The continual pouring of this 160,000,000 gallons (at the two pumping stations) of untreated sewage in the river is a most barbarous and dangerous method of dealing with the drainage of London. This has been well recognised by the authorities, and the Metropolitan Board of Works have had allowed them by the Special Commission a sum not exceeding £200,000 a year for the purpose of establishing means of precipitating and purifying the sewage at the outflows. Experiments of considerable extent have been carried out to deal with this question by chemical means, and quite recently some £30,000 have been spent in chemical precipitation. The chemical method is at work in several towns in England, but is unsatisfactory for several reasons: one is the great expense for chemicals; another is the actual labour in mixing; moreover, the precipitation accomplished, the effluent has still to be oxidised or purified, and the addition of chemicals to the water still tends to a prejudicial effect by reason of its alkalinity.

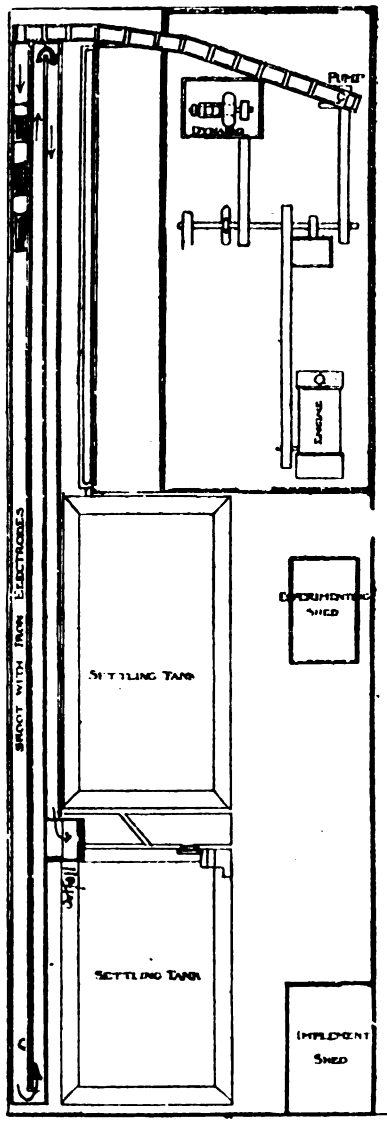

Fig. 1.—Plan of Electric Sewage Works at Crossness.

These defects are entirely overcome by the electrical system of treatment. The cost, as far as can be judged, is much less. The expense of chemical treatment is not accurately known, but varies in different towns from 30s. to 70s. per 1,000,000 gallons, whereas Mr. Webster calculates that the electrical system will cost only 13s. per 1,000,000 gallons for the actual cost of working, not including interest and depreciation, or including this, which will vary according to the make of engine and machinery, say, not over 20s. per 1,000,000 gallons. Mr. Webster, therefore, calculates that for the actual cost of working, the amount for purifying the total London sewage will be about £36,000 a year. When it is remarked that the authorities have been considering the expenditure of over £100,000 a year for this purpose by chemical means, the saving of the electrical process can be seen at once Even calling it £50,000 or £60,000 a year, this would be

Digitized by Google

one-half the expenditure proposed, and even cost for cost a better effect would be produced by the electrical process.

The Principle of the Electrical Treatment.

Mr. Webster has been working in connection with sewage and water treatment most of his life, and was for some time a pupil of the late Dr. Letheby, who in 1857 recommended the Metropolitan Board of Works to try the lime process or the sulphate of iron process for precipitating the sewage. Mr. Webster conceived the idea that the precipitation might be brought about by electrolysis, and made some experiments to carry out this process with carbon plates; but it was not until about three years ago that the idea of using iron plates as electrodes, which has made the process a success, occurred to him.

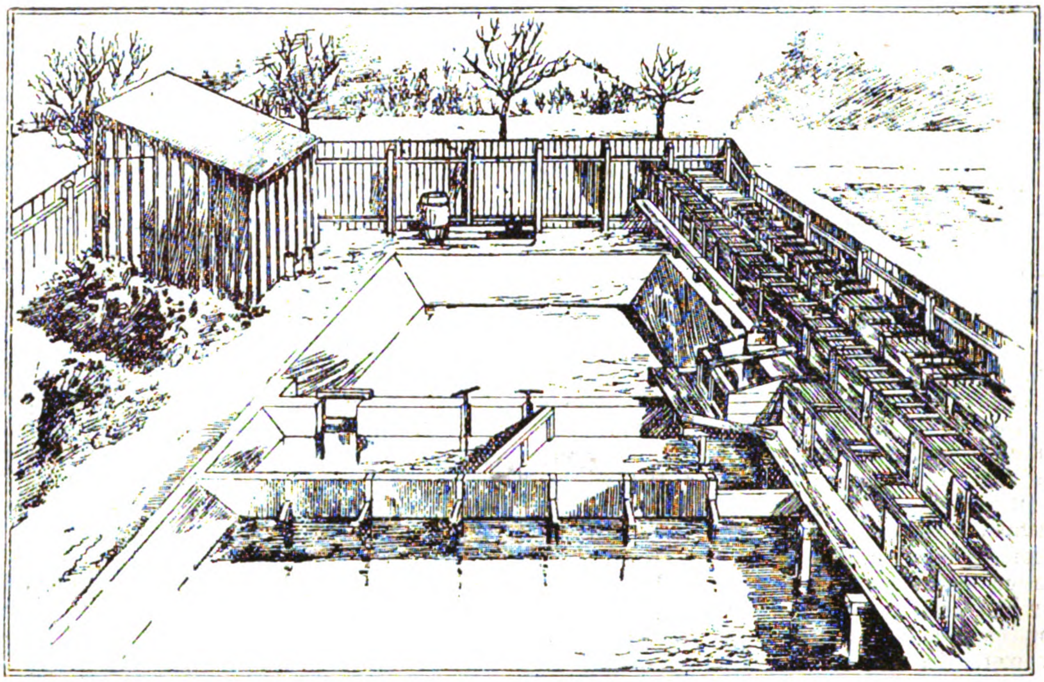

Fig. 2.—View of the Shoots.

On Wednesday, Mr. Webster showed some experiments with test-glasses of sewage, heated by electrolysis, with iron electrodes, to illustrate the action which takes place in his system. Several tall glasses were filled with sewage of varying strength, taken from the pumping station the day before. Wires were led from the dynamo to a pair of electrodes, which consisted of three long strips of iron on a wood frame; and when this simple arrangement was placed in the vessel and twisted about ebullition at once commenced, the matter in suspension became flocculent and rose in a scum to the top. In a few minutes the absolutely black and opaque liquid became variegated, the particles became detached, and shortly the liquid became more or less clear, with the solid matter separated. The scum and solid matter rises at first with the ebullition of hydrogen to the top, but afterwards subsides, and the effluent can be run off. The reaction is supposed to be as follows: At the positive pole nascent chloride and oxygen are given off, forming hypo-chlorite of iron. This hypo-chlorite of iron is precipitated by the ammonia, soda, etc., at the negative pole, and forms hydrated ferrous oxide. This particular oxide has the property of combining with organic matter, and flocculent particles are formed, which carry away the whole of the matter in suspension. The organic matter in solution is oxidised, and with proper care the water may be drawn off perfectly pure and bright. That the matter in solution is precipitated, was shown by the action of the same current upon a tube of water tinted with an aniline dye, the colour of which was rapidly taken out by the action. The effluent water, as a rule, is not only purified, but has actually gone to the other side, and remains a disinfectant. The effect of the bleaching quality of the sewage after treating was illustrated in another experiment: the characteristic smell of chlorine could be distinctly smelt upon shaking the specimen, and a little added to a glass of water which had been tinted with indigo rapidly took out the colour, showing the bleaching effect of the treated sewage.

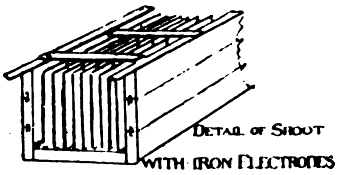

Fig. 3.

The Method in Practice.

At first the method adopted was similar to that of the test-tubes on a much larger scale. Huge tanks were erected, and plates of iron were connected and placed in these tanks; the whole quantity of sewage was heated and then drawn off to settle while a second lot was run into the tanks. It was found, however, that a continual motion of the electrodes was required to get sufficient contact with the liquid, and it was decided to abandon the tank system and adopt the method of having the liquid in motion instead of the plates.

The system now at work at Crossness is illustrated in the accompanying figures, Fig. 1 being plan of the works. It consists, in effect, of a long shoot doubled twice upon itself, down which the sewage gently flows after having been pumped up by the pump at one end (see view of the shoots, Fig. 2). All along this shoot are placed the electrodes in groups of 15 plates each. The arrangement of the plates on the shoot is shown in Fig. 3, the plates lying along the direction of the current. There are 22 sets of 15 plates each in parallel, and six such sets in series. The electrical pressure across the electrodes is 2·8 volts; the total pressure is therefore six times this, and, allowing a certain loss in the leads, makes the pressure at the dynamo to be 20 volts. The manner of connection between the sets in series is illustrated by the diagram, Fig. 4. The shoot is of wood, but in any permanent work it would be of brick, concrete, or iron, and the bottom would be lined with asphalte or other suitable material. The plates at present are of wrought iron, but for ordinary work would be cast out of ordinary pig iron.

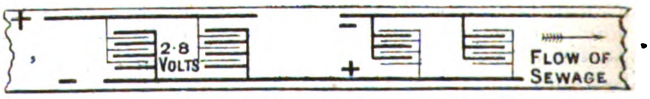

Fig. 4.—Diagram of Electrical Connections.

The sewage as it comes in flows along the upper shoot

Digitized by Google

and back again twice, all the while passing between the electrodes ; every particle comes in contact with the plates and becomes electrolysised. By the time it has got to the outfall, a few minutes only, it is sufficiently treated ; it is run into one or other of the settling tanks and allowed to settle for an hour, perhaps two, and the effluent is then run off into the river. Such is Mr. Webster's system of electrical treatment of sewage, a simple and eminently scientific method, which cannot fail to entirely revolutionise the systems of town disposal of sewage.

THE DYNAMO HOUSE.

The dynamo used is an Edison-Hopkinson, working at a pressure of 20 volts, and capable of developing an energy of 43 h.p. The whole of the current is not at present utilised, about 500 amperes being the quantity now employed. The dynamo is driven, by means of counter-shafting, by an engine of old type, made some 25 years ago, of 20 h.p.

The speed of the dynamo is regulated by a Rung's pneumatic speed indicator, connected with the dynamo, but placed beside the engine-driver. The regulation of the strength of current for the different qualities of sewage is very simple. All that is required is to keep the voltmeter at 2·8 volts across the electrodes. If the rain falls, the voltmeter immediately goes up to 3 volts or over by increase of resistance, and the speed of the dynamo is then lowered to give the usual pressure.

POWER REQUIRED.

The experiments at Crossness have proved that with 27 h.p. it is possible to treat 1,000,000 gallons of sewage in 24 hours. These figures relate to London sewage, where the rainfall is mixed with the sewage. For towns where the rainfall is distinct, less power would be required, for the stronger the sewage in chlorides, etc., the less the electrical resistance.

As to the cost of the engine power, we need hardly state that the newest type of engines suitable for driving dynamos may be taken to consume two pounds of coal per h.p. hour, and according to the price of the coal will be the working cost. The experiments carried out with reference to the amount of iron consumed by this process tend to prove that the consumption in continuous working should not be more than two grains per gallon. Here, again, the cost entirely depends upon the district in which the works are situated, with regard to the price of pig iron. The plates are 1in. thick, and if used in sufficient numbers would last for many years when once fixed. For instance, a town with a flow of ten million gallons of sewage per day, corresponding to a population of 333,000 at 30 gallons per head, will require to treat this amount of sewage a consumption of iron not exceeding 464 tons per annum. On calculating the amount of mechanical power required per head of the population, Mr. Webster finds it represents $\frac{1}{1225}$ of a h.p., or 8 h.p. per 10,000.

It will be seen that the above plant is practically in lieu of the mixing-tanks, machinery, and chemicals employed in chemical processes for the treatment of sewage, and if such electrical plant is designed to meet the peculiar requirements of any particular district it should cost much less and have a greater efficiency than any other process known, for not only does this electrical method precipitate the matters in suspension, but it also removes organic matter in solution, and forms a precipitating and disinfecting process in one operation.

THE SYSTEM IN PRACTICE.

The present works—where the system is shown in operation at the rate of 12,000 gallons per hour—have cost Mr. Webster some £5,000 to erect and carry on, and in the work of experimenting and arrangement of the station he has been ably assisted by Mr. March, his assistant electrician. In carrying the system into practice, Mr. Webster does not intend to carry out the work himself, having already as large a business as contractor as he is able to conveniently manage, and he is now building the precipitating tanks at Crossness which will be used whichever system, chemical or electrical, is ultimately adopted. Mr. Webster has carried the system to a practical point, and wishes rather to arrange with sanitary or electrical engineers or town authorities to work his system under a royalty.

The average of 20 analyses taken at Crossness during 1888-9 show that of raw sewage, very turbid and opalescent, containing 33·35 parts of suspended matter in 100,000, the effluent was clear, containing 1·56 parts per 100,000.

SETTLING TANK.

The visitors on Wednesday were shown a new settling tank invented by Mr. Houghton, son of the engineer to the sewage works, which is extremely ingenious and simple, not necessarily part of the electrical treatment, but which will probably be employed in the new precipitation, etc., works at Crossness. One side of the tank is composed of a series of shutters like venetian blinds, which fall outwards, one after the other, to let the water out. A float behind the shutters, rising as the water rises, closes the shutters, each locking the one below. When the tank is full, after being left to settle, the water begins to flow over the top shutter, the float falls, and the shutters open one after the other downwards, drawing the water off the top always, and allowing the sediment to remain without disturbance from currents.

CORRESPONDENCE.

ELECTRIC LIGHT CIRCUITS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I have read Mr. Fish's paper in your last issue with much interest, but I find it impossible not to take exception to his first conclusion, as to the standard of insulation to be adopted in order to obtain immunity from danger to human life. I object to it principally for two reasons : (1) that R is a variable and not a fixed resistance, and (2) the value of C as a death-dealing factor is not known with sufficient accuracy. Mr. Fish having obtained 4,000ω to 15,000ω as the hand-to-hand resistance of several persons, takes a somewhat curious mean of 5,000ω—a hard and fast mean, be it observed—and proceeds to calculate the value of C in each case, assuming E and R to be fixed quantities. Now this appears to me to possess the solidity and safety of the house built upon a quicksand : it's all right, so long as nothing comes along to disturb it. The mean of 5,000ω is, all things considered, a rather low value to take as the normal hand-to-hand resistance of the body *when the hands are dry*. My own tests are higher ; but it is also a fact that if the hands are moist—if the high skin resistance is partially neutralised—the resistance falls to 400ω or 500ω, and in this case Mr. Fish's first value would be

$$\frac{1,000}{500} = 2 \text{ amperes.}$$

To my mind, a provision which depends upon an uncertain and extremely variable physical condition, upon the nature of the contact made, and upon other considerations which it is not necessary at present to discuss, is by no means satisfactory. The matter is an important one, but as the question really deals with workshop practice, not calling for any elaborate theories, would it not be best met by taking means to ensure the invariability of R within reasonable limits? This might be done with less trouble than is now entailed by the precautions governing the safety of coalminers, and if insisted upon by those having control of electric light and power enterprises, should procure immunity from danger for those engaged in practical work. Suitable clothing, etc., should be worn, and the hands and wrists soaked in a non-conducting oil or composition, or frequently dried with a naphtha or paraffin rag. Before engaging in any possibly dangerous work the resistance of the operatives should be measured. In this way the risk would be greatly minimised. You would not venture to place a delicate instrument in circuit with an unknown E.M.F., why should you, then, venture a human life blindly? If a law were passed prohibiting the employment of workmen whose hand-to-hand resistance should at any time during working hours be less than ten times the voltage, a way would very soon be found out of the difficulty.—Yours, etc.,

QUERIST.

SOME ELECTRIC LIGHTING CENTRAL STATIONS IN EUROPE AND THEIR LESSONS.*

BY PROF. GEORGE FORBES, F.R.SS. (L. AND E.), MEMBER.

(Concluded from page 243.)

I am not going to discuss at present the whole question of insulation, but rather to draw conclusions from the experience of the past. At the present moment vulcanised indiarubber and okonite are the substances which have the highest reputation for durability and high insulation under all conditions. These, like other cables, are sometimes covered with lead, but in their case it is only as a mechanical protection, especially during the process of laying, because the destruction of the lead would not destroy the insulation. Of late years a class of cables has been much praised, about which I wish to speak. The copper conductor, stranded or otherwise, is covered with any fibrous material, preferably jute, impregnated with bituminous oils. This covered core is enclosed in the lead pipe. In this class of cable the insulation depends upon the lead being water-tight. We all know of many places where this type of cable has done good work for a limited time, and many of us were inclined to believe that it was quite satisfactory; but I think I am right in saying that none of us know of its having worked successfully in any place for three or four years. I have said that a cable of this kind has hitherto been exclusively used in Berlin, the lead being covered with layers of tape or braid soaked in a preservative compound, and the whole armour-plated with two closed spirals of iron ribbon. I regret to have to tell you that this insulation has been a failure. It goes on well enough for about three years, then the lead gives way, the covering on the copper is permeated, and chemical or voltaic action sets up in the copper, which itself becomes disintegrated. So far as experience goes, this type of cable seems to me to be unsuitable for permanent work with the electric light. I trust that in the discussion we shall have some facts brought out. I had hoped, from what Berthoud and Borel, and also Waring, had done, that this would not be so, but the Berlin experience leads me to think otherwise; and on looking through the testimonials of makers I do not find that these cables, when placed underground, have ever worked electric light circuits beyond the three years fixed by the Berlin people as being destructive. I have been told, but I cannot believe it, that there is one company in London actually proposing to put such lead-covered cables without covering into iron pipes. Of course, everyone knows they would soon be eaten into by galvanic action.

At Berlin and elsewhere I believe there is the intention of trying some modification of the system of using bare conductors, first practically used by Mr. Crompton at South Kensington. Taking economy into account, it is probable that for low-tension circuits this is an admirable plan. It is probable that it may also be adapted to high-tension circuits by using oil insulators to support the bare conductors. When copper strip is used, it is necessary to raise the cover of the trough in order to increase the number of conductors: this is very expensive. For my own part, I would prefer a drawing-in system, if it were otherwise equally good.

No information has ever been given as to (1) the maximum or (2) the minimum insulation resistance of the conductors at Kensington Court, but perhaps this information will be given during the discussion.

At the present moment it seems to me that the only types of underground cable proved suitable for permanent work are either bare copper supported on insulators, or else vulcanised indiarubber, or perhaps okonite. Especial care must be taken to avoid an insulator which is injured by the gases which permeate the soil of a town, or which has the property, like pitch, of becoming viscous, and so letting the copper become decentralised.

Meters.

The next lesson which the experience of foreign stations in Europe and America has taught us is the importance of charging the consumers of electricity by meter, like gas. I find that at present most companies in this country are charging the larger proportion of their consumers by contract, making an annual charge for each lamp. This appears, from evidence collected everywhere, to be a fatal mistake. It is the universal experience that those stations pay best where meters are used. In many stations it is found to be the best plan to make a fixed annual charge, which may be put down as the rent of meter, and then an additional charge proportionate to the quantity of electric current supplied. This has the advantage of preventing customers putting in place a large number of lamps which during the greater portion of the year are idle, but which on festival occasions may all require current. Such idle lamps are very expensive to the suppliers, because a large reserve of machinery must be lying idle during the whole year to be ready for such occasions.

Within the last month I have described before the Society of Arts* the different meters which are valuable, without pretending to estimate their relative value. For continuous currents we have the Edison and Aron meters, for alternating currents we have the Schallenberger meter, and for both classes my own "Windmill" meter.

Converters.

The induction apparatus used with alternating currents is called a "converter," "secondary generator," or "transformer." The reduction of pressure from the primary to the secondary circuit is generally 20 to 1, but sometimes more. A large number of types have been invented. I have elsewhere described the Westinghouse converter, which I have tested and found to be very efficient, even though the largest one he is in the habit of supplying is only for 40 lights.

Only the larger size of Zipernowski converter is so efficient. Three sizes are made, varying in efficiency from 95 down to 88 per cent., though the latter is a converter suitable for 25 lamps. Many of the types which are made in England I feel sure are far from efficient. There is a general opinion that the loss in the converter is necessarily small. This is by no means the case. A great deal of care must be taken in the design to get a satisfactory result. I think there is a general idea that any of the converters now on the market in England will give an efficiency for the average number of lamps in circuit of about 90 to 95 per cent. I should be much surprised if there are more than two types in use in this country which have an efficiency for the average number of lamps over 70 per cent. Yet, so far as I am aware, no maker in this country ever tests the efficiency of the converters which he supplies. The efficiency of a converter falls when it is under-loaded. If the converter in a house is adapted for 100 lamps, and only three or four lamps are in use, then, with many converters, the current which is being used is double or treble what is required for the lamps. This defect in some converters is clearly shown in the load diagram of the Grosvenor Gallery installation, where during the hours of minimum supply the current sent out from the station is seen to be abnormally high—far above that of the load diagram of other central stations—and at the hours from 4 to 6 a.m. in October current sufficient for 4,000 lamps is indicated on the station meter. This curve shows a loss of 20 per cent. The type of converter which Westinghouse has perfected is one of low magnetic resistance. The worst ones now being made in England are of high magnetic resistance. The waste in a converter, independent of magnetic friction, varies as the square of the magnetic resistance.† The waste due to magnetic friction varies as the length of the magnetic circuit, if the induction in the iron is the same. These high magnetic resistance converters require a great deal of copper. The magnetic friction is so great that they would probably work better with an open magnetic circuit, as shown by Lord Rayleigh (*Phil. Mag.*, 1886).

Slow and High Speed Engines.

I need hardly tell you that the most startling difference I found between the best European and American practice is the question of speed of revolution of dynamos. In America, 1,000 revolutions a minute is the normal speed for an alternator of 250 h.p.; in Rome, the 600 h.p. dynamos revolve at 125 revolutions per minute; at Berlin, the 400 h.p. engines at 80 revolutions per minute. In Europe there is a tendency to condemn high speed as such, whereas high speed is more objectionable only in the type of machine where the revolving part is more massive, less perfectly balanced, less capable of standing centrifugal strains, and has a longer distance between the bearings. In every other point high speed is an advantage, especially in economy of plant. Now compare the Zipernowski and the Westinghouse dynamos, choosing of the former the one without Pacinotti teeth on the armature, as made by Elwell-Parker. These two machines are electrically identical, but in one the armature is fixed, in the other the field-magnets. The armature can, and the field-magnets cannot, be perfectly balanced. The weights are not very different. The armature is more capable of standing centrifugal strains than the coils of the field-magnets. For all these reasons, the Westinghouse may be run at high speed, and gain all the advantages of economy. Of course the necessity of introducing belting has to be considered in this case. But then turn to the Parsons alternator, which drives direct, and being the lightest, best-balanced machine, with great capacity of resisting centrifugal strains, and with the only scientific bearings in the market. Here we have a machine where all the advantages of high speed may be safely acquired and great economy introduced. People are apt to forget that slow speed means large machines with no increase of output.

Speed of Alternations.

Now I come to a very important point. What speed of alternations shall we use? In Rome they have 83 alternations, or 41 complete periods, per second. In America the Westing-

* Paper read before the Institution of Electrical Engineers, Feb. 28.

* Society of Arts *Journal*, January 25, 1889.

† See my formulæ for converters, *Journal* of the Society of Telegraph Engineers and Electricians, vol. 17, part 71, p. 153.

Digitized by Google

house Company have 267 alternations, or 133 periods, per second. What are the advantages and disadvantages, and why have these makers adopted different plans? I will answer this in detail to the best of my ability. First, Westinghouse went to rapid alternations because he wanted his converters to be of reasonable size. Second, he wanted to economise plant by using high speeds, and it would be very difficult to have slow alternations with high speed. Third, Ganz and Co. (Zipernowski) wanted to drive their machines at slow speeds, under which circumstances they cannot easily get rapid alternations. This is how these things were arrived at. Now let us see what the results are.

1. With rapid alternations the size and cost of the converters is diminished. Most people seem to think this is a small matter. A moment's consideration shows that it is not so. It is found that in most houses the size of the converter does not exactly fit the number of lamps, so a size larger must be used. Hence, for a 7,500-light plant converters for 10,000 lights are required. The price of these, for the sizes used in houses, is (as the average of many makers) £5,000. The cost of engines and dynamos combined (Parsons) for the same would be about £6,000. You will now see that the cost of converters is as important as anything else.

Mr. Kapp has stated, I venture to think erroneously, that the size does not vary with the speed of alternations. This is opposed alike to experience and theory. Westinghouse knows this. I am informed that Mr. Ferranti knows it, and Mr. Zipernowski has told me so in a recent letter.

2. There is, however, an important gain by slowing the alternations. It is then easier to work in parallel. This is due to the fact that the machines have more time to get into step. If I considered parallel working essential to success, I should say, "Sacrifice the cost of converters, and use slow speed." Otherwise, I should say, certainly and without hesitation, "Use rapid alternations to increase the efficiency and economy."

Working in Parallel.

The experience of Rome is encouraging to anyone who thinks parallel working essential. For my part I do not. Subdivision of mains is far more practical in most cases, and enables you easily to cut out special districts if a fire or other trouble occurs. It also gets over the trouble of increased resistance in large conductors with alternating current, dwelt on by our President in his opening address. If I have more than one station in a town, and I want one to assist the other, I would do so by trunk lines between the stations, to which a dynamo can be attached at one end and feeders at the other. Of course, both stations must supply the same type of converters; hence, in such a system it would not do to use dynamos of various speeds of alternations at the different stations. I would certainly prefer parallel working as being simpler for the men at the central station, if no complications are introduced to make the machines work in parallel, and if the system were equally economical, but I do not consider it at all essential. I venture to think, however, that the plan now universally proposed for making machines work in parallel will not long be tolerated. This is to introduce into the machine a large amount of injurious self-induction, thus diminishing the plant efficiency and rendering the equalising of pressure with varying loads very difficult. I have confidence in the ingenuity of our inventors, who will soon devise a less objectionable plan.

Automatic or Hand Regulation.

The question now arises whether the regulation of potential should be accomplished by hand or automatically. In all low-pressure systems, such as Berlin, it is done by hand. A workman soon gets to know at what hours special attention must be paid to this, and on the low-tension system with shunt-wound or compound-wound machines the regulation required is slight. Where the saving in attention is not very great it is always unadvisable to trust to automatic dodges. The case of alternating-current dynamos with high self-induction is very different, for the electric pressure then varies enormously with the current. In this connection such a machine resembles a series-wound direct-current machine with high resistance. The changes are so frequent that some automatic adjustment is necessary. Ferranti, Lowrie, and others have used the sagging of a wire to effect this, and they regulate the pressure at the dynamo, not at the centres of distribution, which is wrong. The apparatus looks too delicate for an engine-room. But Ganz and Co. use a very practical type. They also regulate for the centres of distribution. I also prefer the method used by Ganz and Co. of regulating the large changes by hand, and only the small changes automatically. This is necessary, owing to the very large adjustments necessary with alternators of high self-induction.

In conclusion, I feel confident that all those who are working to maintain England's supremacy in this department of industry will agree with me that the practical details necessary for successful central station working must be thoroughly well thought out beforehand, and that much saving of time and money can be effected by gathering hints from those who have spent years of time and tens of thousands of pounds on these details.

I frankly admit that I have learnt more that is of practical value in this line from the inspection of actual work done than by reading books.

But we must remember that the low price of gas in England, the cheapness of coal, and the relative cost of labour, all introduce special factors which will partially differentiate the English practice either from that of the continent of Europe or of America.

I wish, now, that the last words of this paper may be words of thanks to the gentlemen in other countries—whether in Europe or in America—who have the control of central stations for the courtesy which they have extended to me in my endeavours to assist, to the feeble extent possible to me, in maintaining the position of this country in the progress of this new and important industry.

LONDON COUNTY COUNCIL.

At the meeting of the London County Council on Tuesday last, the General Purposes Committee reported that they had had before them the following important letter from the Board of Trade:

"Board of Trade (Railway Department),
London, March 13, 1889.

"My Lord,—I am desired by the President of the Board of Trade to inform your lordship that the question of electric lighting in the metropolis is at present receiving the serious consideration of this department. Thirteen applications for provisional orders under the provisions of the Electric Lighting Acts, 1882 and 1888, in respect of areas within the metropolis, are now before the Board.

"In dealing with these applications the Board of Trade are at once confronted with two important questions of principle—(1) What should be the extent and nature of the area to be granted? (2) Should or should not concurrent powers be granted to two or more companies within the same area?

"As regards the former, many considerations must be taken into account—*e.g.*, what is the financial position of the undertakers applying for statutory powers in any given area; how far any one company would be in a position satisfactorily to supply such an area; and in connection with this much would depend on what distance electrical energy for electric lighting purposes can be safely and conveniently furnished from a central station.

"As regards the latter question, on the one hand it appears to the Board of Trade to be highly desirable to avoid the grave inconvenience to which the public were subjected when there were competing gas companies supplying the same areas in the metropolis, and, further, in the case of electric lighting, that uncertainty exists whether mains can be satisfactorily laid in close proximity to each other. On the other hand, some of the local authorities in the metropolis appear to be desirous to encourage competition, and are anxious to avoid the creation of a monopoly or *quasi*-monopoly for electric lighting by giving any company exclusive powers for any one area.

"Before deciding on the action to be taken on the applications at present before the Board of Trade, they propose to adopt their usual procedure and to hold a local enquiry, of which full notice will be given, and at which all those interested can be heard, but they are anxious to take no definite step which may have important bearing on the future policy to be pursued with regard to electric lighting in the metropolis without communicating in the fullest manner with the County Council of London.

"In this determination they are greatly influenced by the consideration that before long the jurisdiction which the Board of Trade now exercise in regard to electric lighting matters in the metropolis may be transferred to the County Council, and they would therefore be most unwilling to take any action which might hamper that body in dealing with the question in the future.

"With this view they propose, as soon as the report of the enquiry has been received, to forward it to your lordship for the information of the County Council, and I am at the same time to express a hope that this Board may then be favoured with any observations which the County Council might wish to offer upon this large and very important question.—I have the honour to be, my lord, your lordship's obedient servant

"Henry G. Calcraft.

"The Earl of Rosebery."

The committee had also received a further letter from the Board of Trade stating that the local enquiry referred to would take place on April 3 next, at 10.30, before Major Marindin, R.E., at No. 8, Richmond-terrace, Whitehall.

It was agreed that several members of the committee should attend the enquiry.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months'	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

THE BOARD OF TRADE.

The letter of Mr. Calcraft, from the Board of Trade, to Lord Rosebery, the chairman of the London County Council, is just at this moment of great interest. The letter is given elsewhere. It states that at the present time there are 13 applications for provisional orders for metropolitan districts under consideration at the Board of Trade. Further, before deciding upon the action to be taken on these applications, it is intended to hold a local enquiry, which enquiry is to be held on the 3rd of April next, at 10.30, before Major Marindin, R.E., at No. 8, Richmond-terrace, Whitehall. The result of this local enquiry will undoubtedly be of very great, if not of supreme, importance to the electrical industry, so far as the distribution of light and power are concerned. Mr. Calcraft's letter mentions two important questions of principle involved in the consideration of the applications: (1) What should be the extent and nature of the area to be granted? (2) Should or should not concurrent powers be granted to two or more companies within the same area?

With all due deference to the wisdom of the Board of Trade, we should say these questions do not really merit five minutes' consideration. The answer to the first cannot be foretold by any system of rules and regulations. The extent depends upon the capital of the supply company; the nature cannot be affected by any regulations of the Board of Trade. Their rules will not turn a residential into a manufacturing district, nor an area covered with artisans' dwellings into streets of theatres. But we should contend that the "extent of area" depends again upon the answer to the second question, "concurrent powers" or "non-concurrent powers." Men who contend that "concurrent powers" should be granted for the purpose of encouraging competition, are not far removed from the category of those dubbed by Carlyle as mostly inhabiting this mundane sphere of ours. If the Board of Trade, or any other authority, be desirous of seeing supply companies "cut each other's throats" at the expense of shareholders, let concurrent powers be granted. Otherwise, rigidly exclude one company from another's district. There are a hundred sensible ways of keeping down "selling prices," rather than driving merrily along the road to the Bankruptcy Court. If electric lighting is to be a success, two sets of distributing mains cannot be permitted in the same district. If such a system did not quite double the initial cost, it would nearly do so; and the cost of maintenance, and the cost of litigation, would be enormously increased. It is useless to consider electric lighting in the dilettante way half the supply companies and contractors would have it considered. If they obtain a provisional order for a district, their aim should be to light every room, be it in princely mansion or labourer's

Digitized by Google

hut, in the district. They should not be permitted to pick or choose; but this really seems to be provided for in the Act, and so need not be discussed. The plans of the supply company should be sufficiently elastic from the very first to permit the supply of all the electric energy, both for light and power, likely to be wanted in the district, not only in the immediate present, but in the distant future. The gas companies do not lay mains of only sufficient capacity to supply two houses now built along a long road in a new district, but of sufficient capacity to supply all the houses in the road when they are built. The district allotted then to any company should be proportional to the capital of the company—that capital being sufficient to enable the whole area to be supplied. A more important question by far than either of these drafted by the Board of Trade is, whether concurrent powers should be given to different companies for the distribution of light and power. At the present moment those who favour the alternate current system of distribution cannot provide for power users, and the question whether the wants of the latter are to be supplied by another company in the same district, is important. Here, again, English notions seem to us to follow the motions of a cat dancing on hot bricks, ever changing, never resting for a moment on the same spot. The letter of Mr. Calcraft does not seem to contemplate the double distribution, and yet the one not referred to is commercially of far greater value than the one mentioned. We again say it seems a sheer waste of money to have two distributing systems, even if one be for light and the other for power, in any district. Probably the enquiry to be held will lead to the expression of various opinions upon this subject, and may elicit information not at present accessible to the public. We are convinced, however, that the questions cannot be separated. It will, perhaps, be advantageous to the industry when the powers governing the metropolitan area are handed over to the Council, for then the subject can be looked at as a whole, while now each application has to be treated separately and individually, except, of course, when several applications are for the same district.

The electrical industry should be well represented at this local enquiry, and see that the right sort of evidence is given, evidence the result of personal experience, and of a practical character, and not evidence of the "I believe" character. What is wanted is the "I know," no matter how egotistical it may seem, in contradistinction to "I have heard," "I have seen," and "I believe." The man not actually engaged in the work is always twelve months or more behind those who are always constantly putting down and arranging installations. If subsequently this enquiry has a bad influence upon the industry, there will be no one to blame but the members of the profession themselves. We trust, too, that the evidence tendered will be on a wider basis than individual welfare. The aim should be to guide the Board of Trade and the London County Council in the right direction for the true development of distribution of electrical energy. It must be recognised that whatever action is taken by the London County Council will have a very direct influence upon every other Council in the kingdom that has to consider similar questions.

USEFUL ELECTRICAL QUESTIONS FOR TROPICAL CLIMATES.

We are always glad to hear from our able and esteemed contemporary, the *Electrical Review*, but we fancy that in this instance our queries have been misunderstood. We asked these questions with a view to obtaining a record of the experiences of our readers in the tropics; whereas our contemporary, taking it for granted that the conditions are everywhere the same, has disposed of the whole matter with a few cut and dried extracts from Clark and Sabine. The questions we asked were as follows:

1. Is the coefficient of variation of resistance with temperature mathematically correct for copper coils, and more especially galvanometer-coils?
2. Is capacity variable with temperature?
3. Are high-resistance coils of platinum-silver reliable, or is it not a fact that, under certain climatic conditions, they show residual charge—that is, act to a certain extent as a secondary cell, destroying the accuracy of tests?

Now, we have not asked these questions without good and sufficient reason, and we venture to think that in the immediate future we shall be able to place a few interesting facts before our readers.

With regard to the coefficient for copper coils, 0·209 per cent. per degree F., it is all right, of course, within the limit of reasonable temperatures; but is it correct when the temperature is excessive? Take, for instance, the case of a galvanometer whose adjusted resistance is 6438 ohms at 66deg. F. The temperature at time of test is 110deg. F., a difference of 44deg., or in resistance of 592 ohms (about). When our readers get these differences, let them test their galvanometers and see if the calculated equals the observed increase. Our experience does not confirm the mathematical accuracy of the coefficient for high temperatures.

In reply to our second question, our contemporary says, "It is generally admitted that the effects of temperature on capacity are, so far as practical work goes, absolutely *nil*." It is a matter of opinion as to whether sufficient is known of condensers to enable us to thus dismiss them as among the subjects that are exhausted. Upon what does capacity depend? Upon the area of the plates, and the nature and uniformity of the dielectric. If the plates vary, and the insulation varies with temperature, capacity must vary as well—whether to any appreciable degree remains to be seen. It may not be noticeable in, say, a ten microfarad condenser, but it is noticeable in a submarine cable of, say, 280 microfarads capacity, whose shore ends are laid through warm shallows. It is only reasonable to suppose that it should be so, for the area of the copper varies with temperature, and the dielectric also varies with temperature, pressure and period of immersion. As a matter of fact, the *apparent* capacity of a submarine cable may be said to vary with the insulation; for the reason that although a higher or lower absolute resistance may not argue a capacity higher or lower than the given quantity while the cable is undergoing electrification, it has a decided influence upon the discharge readings, and therefore allows an error to creep into the test. To make this clear, we will suppose the cable to be theoretically perfect. That being so, it will retain its charge for an

Digitized by Google

indefinite period, and a discharge taken at any time will give the true capacity value. If, however, the cable be imperfect, there will be a loss during the interregnum between charge and observation; and the longer the interval and the lower the resistance of the dielectric the greater that loss will be. It will be admitted that in the event of a broken-continuity fault we have to rely entirely upon the standard capacity of the cable. We will suppose this to be 0·350 micro per knot, and further suppose the cable to have a length of 1,000 knots, thus

A	50 knots	900 knots	50 knots	B
	Hot shallows	Deep sea.	Hot shallows	

The value 0·350 micro per unit of length is, under the most favourable conditions, obtained from a test of the total capacity (taken shortly after immersion) divided by the length in knots. The value is given, and no one troubles further about it. It is unalterable.

Some years afterwards, in the middle of a tropical summer, the cable develops a broken-continuity fault, and we proceed to localise it, heedless of the facts that (1) the insulation basis (if we may be allowed the expression) is changed with prolonged immersion in deep water; (2) the C R is different, owing to difference of temperature; and (3) the shore ends are laid in hot shallows, whereas the deep-sea portion is in cold water. Is the C R the same in the shallows as it is in the remainder of the section? Is not the insulation resistance much lower? There is not the same loss of current throughout; the cable is not homogeneous, and cannot be considered so, electrostatically or otherwise. We remember a case in point. The deep-sea section of a 950-knot cable, tested from the ship, gave very nearly the correct—that is, the standard—capacity, but the 40-knot shore end laid in shallow water presented an abnormally low insulation resistance, and tested from ship and shore 0·02 micro per knot less, which, according to the stated capacity of that particular cable, made a difference in the length of three knots—a very appreciable error, for with the end sealed and the 40-knot section perfect, the capacity test (if the standard electrostatic cap: was correct) should have given the distance to within a fathom.

As regards condensers proper, they are continually going wrong in the tropics, and very seldom test to their marked values. We will give some further particulars later on. Meantime we should like our foreign readers to favour us with their experience. We shall have something to say next week about our third question.

ON THE DESIGNING OF CONTINUOUS CURRENT DYNAMO MACHINES.*

BY PROF. JAMIESON, M.I.C.E., F.R.S.E.

The discussion on this paper took place on February 26, 1889.

Prof. Jamieson explained the leading features of his paper by referring to the wall diagrams which he had prepared of the magnetic and electrical circuits of the Kennedy and Faraday dynamos. He concluded by working out the following demonstration of how magnetic fields are measured, and of how Kapp's constants are derived. He also stated what changes had to be made in these constants to suit different degrees of magnetisation and qualities of iron.

Unit Poles.—The force, F, exerted between two poles of strengths, m and m', placed at a distance, L, centimetres from each other, is

$$F = \frac{m \times m'}{L^2} \text{ dynes.}$$

If m and m' are each unit poles, and their distance apart is 1 centimetre, then

$$F = \frac{m \times m'}{L^2} = \frac{1 \times 1}{1 \times 1} = 1 \text{ dyne of force.}$$

A dyne is unit force in the C.G.S. system, or that force which, if acting for 1 second on a mass of 1 gramme, imparts to it a velocity of 1 centimetre per second.

* Paper read before the Institution of Engineers and Shipbuilders in Scotland.

Method of Reckoning the Number of Magnetic Lines of Force in a Magnetic Field.—Suppose a unit free pole, p, situated at the centre of a non-magnetic sphere of unit radius, r (1 centimetre), and that the whole surface of this sphere is plotted out into squares of unit area (1 square centimetre). Further, suppose that free unit poles, $p_1, p_2 \ldots p_{12}$, are placed at the centres of *each* of these squares, then it follows from the previous statements that the unit pole at the centre of the sphere would exert unit force (or 1 dyne) on each of the unit poles at the surface of the sphere.

But the surface of a sphere $= 4\pi r^2$.

And since $r = 1$ centimetre or unit length, the surface of the sphere is $= 4\pi$ square centimetre; therefore there are 4π dynes of force emanating from the central unit pole, or what is usually termed 4π magnetic lines. Consequently, a magnetic line represents a force of 1 dyne.

If we have any other magnetic pole of strength, M, then the number of lines which flow from it are equal to

$$4\pi M \text{ lines.}$$

Let $M = 100$, then

$$4\pi M = 4 \times 3{\cdot}1416 \times 100 = 1{,}257 \text{ lines.}$$

Magnetic Fields Produced by Currents in Solenoids.—We will make reference here to a spiral conductor or solenoid (without any iron or other core) conveying a current which produces a magnetic field. Then the intensity or number of lines per square centimetre of its cross-section (at right angles to the direction of the lines and at the centre) is equal to

$$\mathbf{H} = \frac{4\pi n C}{l}$$

(see index to symbols below).

In another case the same solenoid is fitted with an iron core, and the same current is supposed to be sent through it. Now, however, we find that the number of magnetic lines per square centimetre of cross-section (within the bar) have increased to

$$\mathbf{B} = \mu \mathbf{H} = \mu \frac{4\pi n C}{l}.$$

1. *Method of deriving Kapp's constant* **2** *from the fundamental formula for* **H** *and* **B**:

Let **H** stand for intensity of field, or C.G.S. lines per square centimetre.

„ **B** „ magnetisation induced by **H** in the iron in C.G.S. lines per square centimetre.

„ μ „ permeability of the iron core.

„ C „ current in solenoid in C.G.S. units.

„ n „ number of turns of spirals in solenoid.

„ l „ length of solenoid in centimetres = 2·5, **L** (inches).

„ s „ cross area of iron in sq. cms. = 6·45 **S** (square inches).

$$\mu = \frac{\mathbf{B}}{\mathbf{H}} \qquad \therefore \mathbf{B} = \mu \mathbf{H}.$$

$$\text{But,} \quad \mathbf{H} = \frac{4\pi n C}{l}, \qquad \therefore \mathbf{B} = \mu \frac{4\pi n C}{l}.$$

Now, as stated before, 1 Kapp line = 6,000 C.G.S. lines.

∴ The Kapp lines induced in the core by current in solenoid equal the

$$\frac{\text{number of C.G.S. lines per sq. in.} \times \text{area of core in sq. ins.}}{6{,}000}$$

$$\mathbf{K}_L = \frac{\mathbf{B} \times \text{area in sq. inches}}{6{,}000} = \mu \frac{4\pi n C \times 6{\cdot}45}{6{,}000 \times 2{\cdot}5} \times \frac{\text{sq. inches.}}{\text{inches.}}$$

$$\text{,,} \quad = \mu \frac{4\pi\, 10\ {}^{1}A \times T_{mw} \times 6{\cdot}45\, \mathbf{S}}{6{,}000 \times 2{\cdot}5\, \mathbf{L}}$$

$$= \mu \frac{3{\cdot}19 \times \text{exciting force} \times \mathbf{S}}{6{,}000 \times \mathbf{L}}$$

But the magnetic resistance

$$\mathbf{R} = \frac{\text{exciting force}}{\text{magnetisation}} = \frac{A \times T_{mw}}{\mu \dfrac{3{\cdot}19\, A \times T_{mw} \times \mathbf{S}}{6{,}000 \times \mathbf{L}}}$$

$$\therefore \mathbf{R} = \frac{6{,}000\, \mathbf{L}}{3{\cdot}19\, \mu\, \mathbf{S}} = 1{,}860 \frac{\mathbf{L}}{\mu \mathbf{S}}.$$

Now, where $\mu = 930$ for magnet wrought iron, as found

Digitized by Google

by experiment, or at the rate of about 14 Kapp lines per square inch,

$$\mathbf{R}_m = \frac{1{,}860\ \mathbf{L}_m}{930\ \mathbf{S}_m} = 2\frac{\mathbf{L}_m}{\mathbf{S}_m}.$$

N.B.—For other values of, μ, the constant **2** varies accordingly.

2. *Precisely in the same way the constant* **1,440** *is found for the air space.* For,

$$\mathbf{R}_{as} = \frac{6{,}000\ \mathbf{L}_{as}}{3{\cdot}19\mu\ \mathbf{S}_{as}} = 1{,}860\frac{\mathbf{L}_{as}}{\mu\ \mathbf{S}_{as}}.$$

Now, if the air space was simply filled with air alone, μ would be equal to 1, and 1,860 would be the constant; but it is to a large extent filled by the insulated copper wire of the armature-coils, and Mr. Kapp has found, from an average of a number of experiments, that this increases the permeability, μ, to 1·36.

Consequently,

$$\mathbf{R}_{as} = \frac{1{,}860\ \mathbf{L}_{as}}{1{\cdot}36\ \mathbf{S}_{as}} = 1{,}440\frac{\mathbf{L}_{as}}{\mathbf{S}_{as}}.$$

N.B.—For other values of μ, the constant **1,440** varies accordingly.

3. *Tangent Function Method for constant* **2**.

Iron molecules when unmagnetised are supposed to lie so 00

When about half saturated they are supposed to be twisted by the magnetic force through an angle, so, *00*

When completely saturated they are supposed to have been turned through 90 deg. from original position, so.. 8

Kapp consequently assumes that the molecules of dynamo iron cores have been twisted through 90 deg. when completely saturated with magnetism, or that the tangent of 90deg. (which is equal to infinity) represents the magnetic resistance in this extreme condition, and the tangent of some intermediate angle represents the magnetic resistance of the actual working magnetisation.

Let σ_m stand for the efficiency of the working magnetisation, or ratio of working magnetisation to complete magnetisation.

Then if 18 Kapp lines per square inch be the working magnetisation of best wrought iron, and 26 Kapp lines per square inch be complete saturation of the iron, whilst the initial magnetic resistance = 1,

Then

$$\sigma_m = \frac{\mathbf{K}\text{ lines per sq. in. working magnetisation}}{\mathbf{K}\text{ lines per sq. in. complete magnetisation}}$$

$$= \frac{18}{26} = 69\%\text{ saturation.}$$

∴ The magnetic resistance $\mathbf{R}_m$

$$= \frac{\text{initial magnetic res} \times \tan \frac{\pi}{2}\sigma_m}{\frac{\pi}{2}\sigma_m}.$$

$$\mathbf{R}_m = \frac{1 \times \tan\ 90^\circ \left|\frac{18}{26}\right.}{\frac{3{\cdot}1416}{2} \times \frac{18}{26}} = \frac{\tan 62^\circ}{1{\cdot}049} = \frac{2{\cdot}13}{1{\cdot}049} = \mathbf{2}\ \text{(nearly)}.$$

From the foregoing it will be observed that Kapp's constants only hold good for particular permeabilities of the different parts of the magnetic circuit. Nevertheless, the formula is an extremely convenient one, and, as has been proved by the examples given, it may be trusted as far as it goes. To those who prefer to refer to tables of magnetic permeabilities, and to work with centimetres, grammes, and seconds, the following formulæ may be used, as more scientifically accurate and elastic in its application.*

The Ampere-Turns on Magnet-Coils.—

$$A \times T_{mw} = \mathbf{M}_a \frac{\left\{ \lambda \frac{\mathbf{L}_m}{\mathbf{S}_m \cdot \mu_m} + 2\frac{\mathbf{L}_{as}}{\mathbf{S}_{as}\ \mu_{as}} + \frac{\mathbf{L}_a}{\mathbf{S}_a \cdot \mu_a}\right.}{4\pi 10^{-1}}.$$

Where $\mathbf{M}_a$ stands for magnetisation of armature in C.G.S. lines.

λ „ the leakage coefficient mentioned before, or $\lambda\ \mathbf{M}_a$ = the magnetisation of the field-magnets—*i.e.*, $\mathbf{M}_a$ is less than the total magnetisation by, say, 20 per cent.

$\mu_m\ \mu_{as}\ \mu_a$ „ the permeabilities of field-magnet iron, air space, and armature core, to be obtained from tests of these or from tables.

$\mathbf{L}_m\ \mathbf{L}_{as}\ \mathbf{L}_a$ „ the same as before, but in centimetres.

$\mathbf{S}_m\ \mathbf{S}_{as}\ \mathbf{S}_a$ „ the same as before, but in square centimetres.

The object of the paper has, however, been to present the calculations and examples in as simple a form as possible, so that they might be understood and applied by any engineer or draughtsman not accustomed to the centimetre-gramme-second system of units.

Sir William Thomson said he felt a great interest in Prof. Jamieson's paper and the statement he had just made to them. The making of dynamos was no longer a thing of the rule of thumb, but everything connected with them was designed beforehand, and a careful carrying out of design ensured well-founded confidence as to what the result would be where it was estimated. That was the fundamental quality of engineering science—to be sure that if proper workmanship were given, the result would be as designed and anticipated. The formulæ put on the board, which were first given practically by Mr. Kapp about three years ago, were of great value in showing dynamo-makers how to do their work. The practical, definite mode of estimating the proper amount of material, and the quality of the same, to be used in the construction of dynamos was of great importance. There were difficulties connected with the quality of the iron which limited the definiteness which could be applied in every case to calculating the result; and here came in the scope for practical experience. He would like to hear what Mr. Jamieson had to say as to the different qualities of cast and malleable iron, and as to the importance of seeking for the very best qualities of iron in respect to magnetic permeability. In most cases of engineering there was a way of getting over defects in the quality of material, and that was by putting in more of it. That method was often eminently unsuccessful. No amount of bad material would compensate for the use of the best material in a great majority of engineering and architectural performances. But there were parts of the dynamo in which a very legitimate compromise between good material in a small quantity and bad material in a larger quantity could be carried out advantageously. One such part was the copper wire in the armature of the dynamo. If they put in a bad quality of copper there they must put in a greater quantity of it; they must increase the air space in which the copper revolved, and they would, therefore, lose enormously in the dynamo efficiency on that account. He need not enlarge upon that point, but everyone knew that in each part of the dynamo the very best quality of conducting material should be used. But now the question of the qualities of iron came in; and he would like to hear Mr. Jamieson upon that point. Suppose they had a field-magnet core of malleable iron, with pole-pieces attached to that core in the usual way, it would be much more readily made of cast iron than of malleable iron. Not only was cast iron cheaper for the same weight of metal, but it was more easily brought into the required shape, for a forging of that shape was much more expensive to produce. Besides the cost of the material the expense of putting it into that form must be considered. By putting in a larger quantity of lower-priced material in the shape of a casting than of better class iron the same purpose was fulfilled. It must be remembered, however, that there were dynamos and dynamos, electric motors and electric motors, and dynamos to be placed in ships and on land, where a difference in weight of two or three hundredweight did not become an important question. On the other hand, dynamos which were to be carried on wheels for electric locomotives, or to be put into certain classes of ships, the question of weight of material came in. He did not say that for a transatlantic liner dynamo a hundredweight or two was of much importance, but where it was to be on a locomotive it was. In speaking of this very simple dynamo made by Rankin Kennedy, he might say that he had had a very favourable experience of it. He was charmed with its simplicity. He had the use of one for some time for a temporary purpose, and liked it so well that he asked Mr. Kennedy to supply him with one, which was now working at the University laboratory exceedingly well. He had not gone into its results particularly to see the amount of work it did, but Prof. Thomas Gray, of the Royal Polytechnic, Indiana, a few months ago made an investigation with the Rankin Kennedy dynamo of the leakage of the lines of force, which they were accus-

* See section on Dynamos, by Prof. S. P. Thompson, D.Sc., in the sixth edition of Munro and Jamieson's pocket-book of "Electrical Rules and Tables," in the press.

Digitized by Google

tomed to call it now. He might diverge here for a moment to call attention to the wonderful perception of Faraday long before the time of dynamos. Long before the time that scientific men knew anything about the distribution of scientific forces, Faraday put it so clear that professors and students, and, a little later, almost every workman, spoke in the language of Faraday of the loss due to leakage of the magnetic lines of force, and in the language of Oily (who figured half a century ago) of the flow or flux of these magnetic lines. Now, Mr. Gray had made an estimate of the leakage of magnetic forces by calculating the total number of lines of force which passed through the effective air space in the Kennedy dynamo in the place where it was effective as compared with the whole number of lines of force calculated by the formula put before the meeting by Mr. Jamieson. He (Mr. Gray) found something like 16 per cent. of leakage, but it was impossible for him (Sir William) to guarantee that figure as absolutely accurate, because Mr. Gray had left Glasgow before they could check it together. This showed that 84 per cent. of the total magnetic force generated was effective; but he trusted that others would pursue the investigation more fully. This matter was obviously of great importance with reference to its relation to the economy of the field-magnets. They would understand that some of the lines of force went this way and others that way [illustrating on the blackboard], and if a pocket compass was held in the neighbourhood it would be found by its action that a very strong force existed at some distance from the dynamo. The simplicity of the Rankin Kennedy dynamo was very marked, more particularly when contrasted with the Gramme dynamo, which was of an essentially vicious character, although of a more symmetrical and evenly-balanced form than the other. Some of the more scientific dynamo-makers preferred the Gramme despite its more elaborate construction, considering it had certain advantages which more than compensated that defect. For instance, Messrs. Mather and Platt, the well-known makers of the Manchester dynamo, instead of a single magnet, placed two parallel to each other. That was essentially a vicious arrangement. He did not say that the Manchester machine was not a really good one; but all he wanted to convey was, that this was a vicious arrangement. The total number of lines to be obtained was not increased by using two magnets. If they imagined those two cores of iron put together, and the same quantity of iron put together, the total number of lines of force would be the same as with the two magnets. Now, they compromised matters by putting the two magnets in the way described in order to obtain a symmetrical machine. He did not want to give an opinion as to the amount of the loss of magnetic lines in that machine, which, he believed, had been stated at one-half. The single-bobbin horseshoe dynamo had undoubtedly not the symmetry of the Manchester dynamo, but that quality might seem a doubtful advantage if weighed against the loss of efficiency amounting to, say, one-half of the lines of force, as it must be remembered how small a part of the whole power of the dynamo was devoted to generating these magnetic lines. But here again he had no doubt Prof. Jamieson could set them right by putting the principles involved before them. From a mechanical point of view the support given to the revolving armature in the Gramme machine was very manifest. On the other hand, the great simplicity of the Kennedy form, of which Mr. Jamieson had spoken in terms certainly not too strong, was a valuable characteristic feature, and that form resulted from applying the bearings in a very convenient way. He then referred to several other well-known forms of dynamos, and said that, in his opinion, the best form theoretically for a field-magnet was a semi-circle, but at the same time he pointed out that there would be difficulties experienced in winding on the wire on such a form of field-magnets. It had the advantage over the Kennedy dynamo by giving less leakage, and diminished the length where the magnetism had to be conducted by iron. In the Kennedy dynamo the magnetism had to be conducted through that [pointing to the diagram on the board] with a mass of iron over the magnet giving a comparatively less effective space, but the laying on of the wire was easy. A round, straight core could be easily made, round which the wire could be coiled as easily, and this being so, the ease of making and the smallness of the cost were great recommendations; besides this, cast iron could be used with advantage provided it were in sufficient mass for the lines of force which had to pass through it.

Mr. M'Whirter said, in reply to the invitation of the Chairman, that he did not know he could add anything of importance to the paper which had been so ably touched upon by Sir William Thomson, and, following such authorities as Sir William and the author of the paper, they must all be very careful in expressing any opinion. Sir William Thomson had spoken of the magnetic leakage, or, in other words, the number of lines of force which passed through the armature compared with the number passing through the yoke of field-magnets. Only the other day he (Mr. M'Whirter) had occasion to test a dynamo having field-magnets of the Kapp type—namely, the Edison form inverted. The armature was of the drum type, with Pacinotti core and Siemens winding. The field-magnet cores were of Swedish iron, the yoke and pole-pieces were of cast iron (cold blast and specially soft), the armature core was of Swedish iron discs, slotted for the winding, and carefully insulated to prevent Foucault currents. The leakage was measured with magnetic densities of from 0·55 to 17 Kapp lines per square inch in magnet cores, and throughout this range the leakage increased from 9·5 per cent. to 20 per cent. of the whole lines passing through the magnet yoke. In this dynamo the angle covered by each pole-piece was nearly 150deg., and the leakage at both poles was only about ·4 per cent. at the highest magnetisation obtained during the experiments—namely, about 17 Kapp lines per square inch in magnet cores. Mr. Kapp, in his paper read before the Society of Telegraph Engineers, November, 1886, gave as the saturation density for hammered scrap 18 lines per square inch, but seeing that in this experiment they easily got 17 lines, it was evident that Kapp's value was much too low, or our iron must have been very much better than Kapp's experimental dynamos. As showing the importance of dynamo designing, his firm, in 1884, had occasion to supply two dynamos for ship-lighting running 800 revolutions per minute. He found that these dynamos worked well, the output being, however, only 4,000 watts. Certain alterations suggested themselves to him while testing these dynamos, all in the way of reducing the magnetic resistance. The iron in the magnets was kept of the same section, but the yokes were much increased, and the joints were also much improved. The amount of iron in the armature was also increased by 50 per cent., and the result was, that now at the same speed this dynamo gave 12,000 watts. Some makers of dynamos went in for a very high magnetic density in the armature core. For example, the Kennedy dynamo mentioned in the paper had 21 Kapp lines per square inch of core, but this very high density, he thought, was obtained at too high a price. His own firm were satisfied with 17 to 18 lines per square inch of armature core. From such dynamos they got excellent work, and this density was easily obtained without excessively large magnets. Sir William Thomson had just said that no doubt the future dynamo must be simple in design, and such as could be produced at a reasonable price. His (Mr. M'Whirter's) firm had for some time got all the iron for magnets direct from Sweden; but except for special purposes, when weight was of great moment, they had decided to use in future only cast iron. He might mention that his firm had just made a much simpler dynamo even than the design called "Kennedy's," and in this cast iron was exclusively used for the magnets. The dynamo was made in two castings, including the base for tension frame. With cast iron of the quality he referred to, the permeability was so near that of wrought iron that very little difference in the magnet cores were necessary, and as this cast iron was cheap there was no difficulty in slightly increasing the diameter to make up for its lower permeability. The result of tests showed that without any sacrifice in the efficiency of the dynamo it would certainly be very much reduced in price. It was cold-blast cast iron of good quality that they used.

Mr. J. D. F. Andrews said that Mr. Kapp introduced various constants for the magnetic resistance of the air spaces with different irons, and thought it wrong to suppose the resistance of the air space was anything but constant, independently of the quality of the iron, and that consequently that constant should be varied which refers to the different qualities of iron. He also suggested the use of ampere feet per square inch of cross-section instead of ampere turns, as being much easier for the calculation prior to constructing the machine. With regard to the relative dimensions of the field-magnet iron and that of the armature, this had been determined prior to the invention of Mr. Kapp's interesting formulæ. It had been found that increasing the size of the field-magnets the sparking at the commutator was reduced until a certain relative size between the two was reached. The reason for this reduction in the sparking had never been satisfactorily explained, and he thought a correct explanation was that the magnetism produced in the armature core by the electric currents, generated in its coils, was more powerful than that in the field magnets at the point of collection, and being of the same polarity, it reduced the strength of the corresponding point in the field-magnet or tended even to reverse the polarity; consequently, the point of collection of the currents was shifted round a few degrees in the direction of rotation to a more powerful point of the field-magnets. If, however, the field-magnets were weak throughout, the point of collection would be always in advance of the brushes, because so soon as the brushes were brought up to that point, the armature current, and consequently magnetism, would increase, and reduce the power of the field-magnets that were generating it.

Mr. R. D. Smillie said that he had lately made some investigations on an old Gramme machine by Messrs. Emerson and Murgatroyd, of Stockport—a firm, he believed, now extinct—which showed the necessity of having reliable constructive data. Prof. Jamieson had drawn attention to the throttling effect due to defective design in the magnetic circuit of the small motor exhibited by him to the members. The Gramme machine referred to showed this in a remarkable degree, the magnetic permeability of the yokes relative to the cores of the

Digitized by Google

field coils, which were of malleable iron, being only 37 per cent. The amount of iron in the armature core relative to the field cores was much too small, and, considering the intensity of the magnetic field, was far above economical saturation; while the length of the wire on the armature was excessive. The pole-pieces were also badly proportioned, considering the small amount of iron in the armature, as they enveloped 84 per cent. of its circumference, and caused a considerable loss in the magnetic field by short-circuiting in air. This was amply proved by cutting away the horns of the pole-pieces, reducing the enveloped area of the armature to 74 per cent., which had the effect, as was to be expected, of reducing the speed of the machines for the same output, 20 per cent., and also the sparking at the brushes. By clamping soft-iron plates to the yokes of the machine of sufficient sectional area to render them equal to the area of the field cores, and making a new armature, which was now in process of construction, he expected to increase the output of the machine 2·5 times, at its normal speed and with a fair figure of economy.

Mr. A. Tanakadate, being called upon by the Chairman, asked whether there was any physical basis for the assumption of magnetic resistance as constant in the Kapp's formula. He also pointed out that the theory of molecular rotation (which was first given by Weber) failed to agree with the experimental results even after the theory was modified by introducing inter-molecular friction; and stated his strong doubt of the theory by alluding to the recent results in the magnetism of nickel by Mr. Nagaoka.

Prof. Jamieson, in replying to the discussion, said: That at the late hour, and considering the large amount of their time and patience taken up prior to the discussion in explaining and amplifying his paper, it would be out of place to say much more at present. They were all much indebted to Sir William Thomson for pointing out so clearly the leading principles which should control the designing of dynamos. He believed that the remarks made by Mr. M'Whirter, together with the magnetisation curves which he had shown (and which would no doubt be published in the *Proceedings* of the institute) answered Sir William Thomson's request for further information as to the different suitablities of wrought and cast-iron for dynamo construction. Of course, no one would now think of using cast-iron for the armature cores, since the core must be laminated as much as possible, and since it was desirable to obtain a higher degree of magnetisation than could be economically attained by the employment of cast iron. Further, since the weight of the armature and the length of its conductor should be as small as possible (consistent with other conditions), the core should be composed of iron of the highest permeability. In the field-magnets, however, cast iron of comparatively high permeability might now be obtained and employed with marked advantage when lightness is not so much an object as cheapness, and where the sacrifice of a small percentage of electrical efficiency is of less importance than handiness in form, fewness of parts and joints, and general getattableness. Mr. M'Whirter referred to Mr. Kapp's paper in regard to the saturation density of hammered scrap iron. Mr. Kapp, however, qualified his statement by saying that "these figures are not to be taken as generally applicable, but simply as *averages* of the usual qualities of iron now obtainable." He would ask Mr. M'Whirter to give him an opportunity of thoroughly testing his new form of dynamo with magnets, core, and pole-pieces made entirely of cast iron; and, with his permission, he should place the results before the Institution. It was only by careful experiment and trial with different qualities of iron worked at different degrees of magnetisation that they could now hope to make any substantial improvements in or reductions of the cost of dynamos, for the machine was already so very perfect. Mr. Andrews was no doubt correct that practice first gave the stimulus to theory, for the precise relations between the magnetisation of the field-magnet and armature cores, and the exciting force was independently worked out by Dr. Hopkinson and Mr. Kapp, in conjunction with their own practical experiments and the results of dynamo makers. Their formulæ and tests, as well as the discussions upon their papers, had been the means of clearing away the "fog" which previously existed. He hoped that Mr. Smillie would give them the complete data of his experiments when he had reconstructed the old Gramme machine. In answer to Mr. Tanakadate, Kapp's constants were for a particular assumed permeability, and consequently, as mentioned prior to the discussion, they must be varied for different degrees of magnetisation and quality of iron employed. He (Mr. Tanakadate) might be perfectly correct in doubting the assumed theory of molecular rotation, but the idea greatly assisted the imagination in conceiving the observed effects.

The Chairman (Mr. Dyer) said they were highly indebted to Prof. Jamieson for his paper on this important subject, and for the practical manner in which he had embodied the results of mathematical and experimental investigations bearing upon it. Some of these investigations might at first sight seem to be of an abstract nature and to have little relation to practice, but it was found that their results were of the highest importance in the design and manufacture of dynamos. He was glad to learn from Mr. Jamieson that the designs of dynamos could be so exactly worked out now that the whole of their proportions and sizes "can be calculated and drawn down with such accuracy that, when constructed, they will fulfil the stipulated conditions to within 2 or 3 per cent., with a minimum of experiment and alteration in the workshop." Everyone would admit that that showed a high state of advancement. It was satisfactory that electrical engineers had got rid of the term "nominal horse-power," as he had recently been trying to induce mechanical engineers to do the same thing. With the conditions under which the former worked it was a comparatively easy matter to do this, and to have recourse instead to the more accurate system of brake-power. At this late hour he did not think it necessary for him to continue the discussion, more especially after the interesting discussion they had had, but he would like to remark that the paper before them was of such a kind as he would like to see often introduced to their proceedings. It manifested to a great degree the intimate relation which subsisted between science and practice, and it was altogether of such a nature that mechanical engineers would welcome such papers as often as Mr. Jamieson thought proper to prepare and read them. He was of opinion that every session they should have a similar good field night for electrical engineering as the one they now had had. He had only further to ask them to award Prof. Jamieson a hearty vote of thanks for his interesting and useful paper.

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

(*Continued from page 240*).

In the Thomson-Houston lamps, so widely used in the United States, a peculiar clutch is employed, consisting of a pair of levers jointed together, one of them being perforated with an eyelet through which the carbon rod passes. The mechanism of this lamp, shown in Fig. 14, consists of a see-saw lever, L L, pivoted at O, and provided with a long tail, T, the motion of which is moderated by an air dash-pot. Below is an electromagnet, M, in the main circuit, and above is a second, S, which is connected as a shunt. The pole-pieces of both are of conoidal shape, protruding through apertures in the armatures, *a a*, and *b b*, to give longer range of pull. The lower and upper arms of the clutch, marked R and K, close together when the tail, T, rises, gripping the carbon rod, C, and raising it. From this diagram, which also shows the electric connections, it appears that the current entering the lamp through an insulated terminal at + P, flows first round M, and then goes to the frame of the lamp. Thence it divides, the main current finding its way to the upper carbon-holder, and so through the arc to the lower carbon, whence it returns (by a route not shown) to the insulated negative terminal, —P. A smaller portion of the current flows up round the shunt electromagnet to —P. The arc is struck by the preponderating main-circuit current in M attracting the lever end of the see-saw lever, and raising the clutch. The feeding is accomplished by the preponderating pull of the shunt magnet as the arc increases in length. The resistance wire across from + P to C constitutes a cut-out circuit, which is brought into operation by the augmented current in S on any failure of the main current. The small coil connected across from + P to the lamp frame is a mere adjustment to regulate once for all the power of the series-coil, *m*, relatively to that of the shunt-coil, S.

It will be noted that in the operation of all these clutch actions there are really four periods. In striking the arc there is a first stage of affairs, where the clutch rises sufficiently to grip the carbon rod, immediately followed by second stage, during which it rises still further, and lifts the carbon rod, so striking the arc. During the third stage or period the clutch still retains its grip, but as the arc burns away the clutch is gradually lowered. This is due, in constant potential lamps, to the weakening of the main current; in constant current lamps, to the increasing opposing action of the shunt. The fourth stage is reached when the arc has burned away so far that the clutch has been lowered to the point where it begins to relax its grip, and now feeding commences, the rod slipping a little, but the clutch simultaneously rises a little, and grips again, again to descend. In a well-adjusted clutch lamp the clutch is indeed incessantly rising and falling through minute distances about the critical position. A bad clutch, or one that is deranged by dirt, will overfeed, and then rise too far, feeding spasmodically. Theoretically, all these clutches possess the retractile property so useful in keeping a steady arc when the carbons are of indifferent quality. But it is obvious that their perfection of action is impaired by dirt, dust, and inequalities in the surface of the carbon rod due to wear and tear. Clutches of the class termed "forward feeding" belong to a different category, as they have, for the most part, no retractile power. In Newton's form (1623^{83}) a piece of steel curry-comb, bent so as to form a sort of lobster-trap, encircles the carbon rod, and forces it gradually forward when mechanical vibrations are imparted to it by a lever, working with a vibration on the plan of the well-known electric bell vibrator, from the armature of a shunt-magnet. The latest variety of this species of forward feed is that of Holmes (769^{86}) shown in Fig. 15. Here, a shunt electromagnet, S, attracts an armature, *a*; the latter being mounted upon a vertical lever. The carbon rod, CC_1, is gripped between two blocks which are pressed against its sides by two curved springs, s_1 and s_2. The armature lever is attached to s_1, and is connected across by a small rod, *p*, to the

* Paper read before the Society of Arts, March 6th.

Digitized by Google

spring s_2. When the armature, *a*, is alternately vibrated backward and forward by the magnet, the gripping blocks propel the carbon downwards. The make-and-break device which turns the current off and on in the magnet-coils, is not shown in the cut. It consists of an ingenious modification of Holmes' snap-switch.

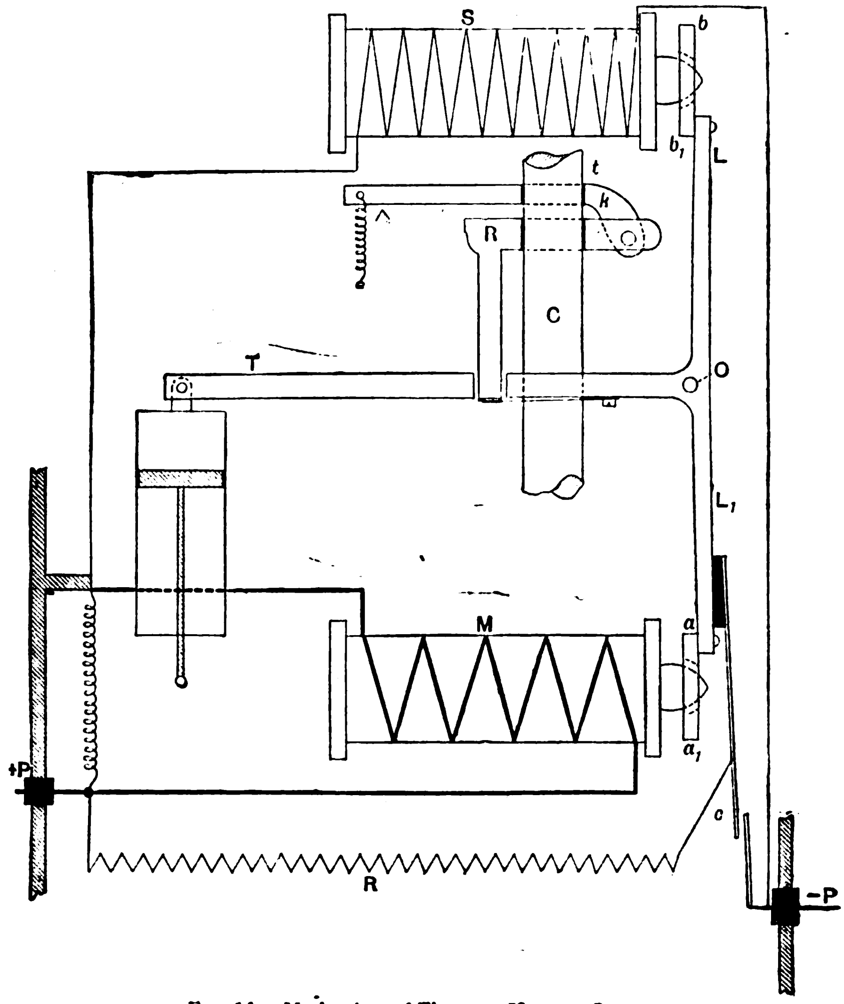

Fig. 14.—Mechanism of Thomson-Houston Lamp.

Passing to the *clutch-wheel* or *brake-wheel* type of lamps, we may remark that although so far back as 1861 Gramme attempted to construct on this plan a lamp (the existence of which was only published to the world in 1888 by M. Fontaine), this species of mechanism appears to be essentially British. The device of applying a clutch to a wheel in order to feed that wheel forward by degrees, the reciprocating motion of the clutch-lever being converted into a motion of rotation of the wheel, is already familiar to engineers in the so-called "silent-feed" movements used in spinning and weaving machinery. A clutch applied to the periphery of a wheel first grips the wheel, then turns it a little. In weaving machinery the "feed" acts in the direction in which the clutch propels the wheel, but in its application to the arc lamp the action is reversed, for the weight of the carbon rod propels the wheel in a direction opposed to the grip of the clutch, and the feeding takes place at those instants when the clutch releases its grip. The matter is best studied by reference to actual cases. Fig. 16 depicts the clutch-wheel of Common and Joel. The descending rack, R, drives the wheel, D, by means of the pivot, P. Pivoted loosely around the same arbor is a heavy lever, which is prevented by a stop,

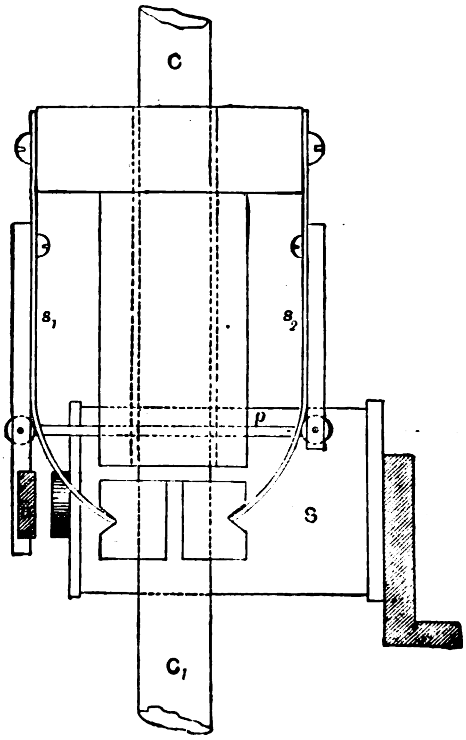

Fig. 15.—Holmes' Feed.

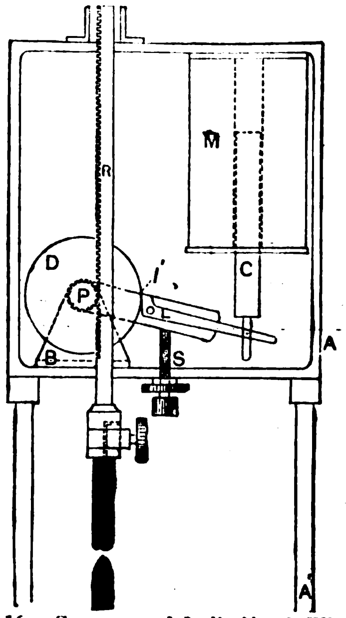

Fig. 16.—Common and Joel's Clutch-Wheel.

S, from descending too far. Pivoted to this lever at L is a second lever, with an enlarged end to grip against the surface of the wheel. The tail of this nipping lever is attached by a pin to the iron core of a solenoid, M. (The latter is wound with a main-circuit coil only if

Digitized by Google

wanted for use in parallel, or with a main coil and an opposing shunt-coil if for use in series.) When the current in the solenoid draws up the core, the nipping lever first turns around L and grips the wheel; any further rise of the core will cause the two levers and the wheel to

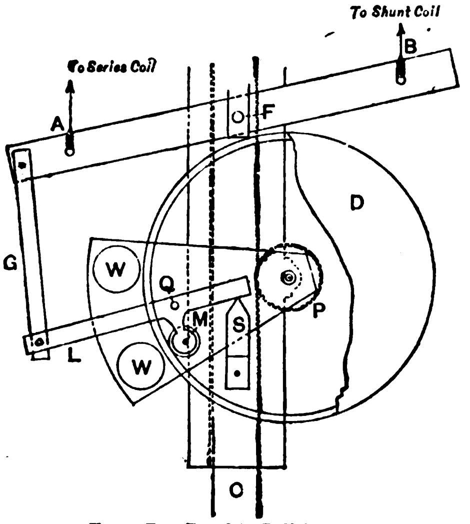

Fig. 17.—Brockie-Pell Lamp.

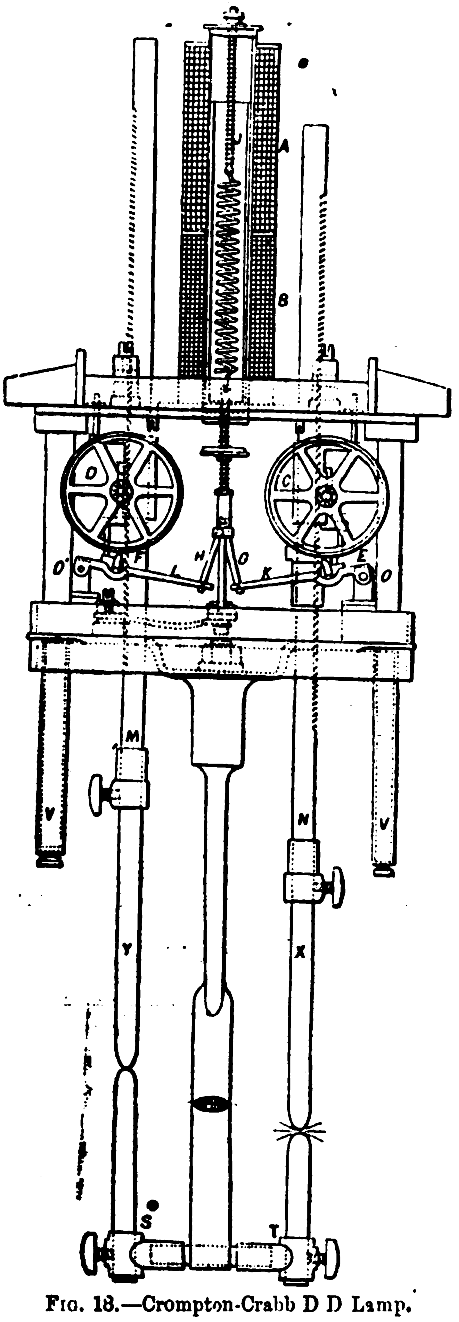

Fig. 18.—Crompton-Crabb D D Lamp.

urn bodily together round the arbor, and this second action causes the arc to be struck. Then begins the third period of action, during which the levers slowly descend until the weight-lever touches S. Then the fourth period begins; any further descent of the core causing the nipping lever to release its grip, and allowing feeding to take place, followed by a slight rise in the core and renewal of grip.

A form of clutch-wheel lamp which has become deservedly popular of late is that known as the Brockie-Pell (4419^{88} and 12681^{88}). The see-saw belonging to this lamp was shown in Fig. 6, of modes of focussing (Fig. 24). The descending carbon-rod drives a wheel having a strong projecting rim, at the inner surface of which a brake is applied. This consists of a small leather pad, *m*, fastened to a short arm which projects downwards from the nipping lever, L, pivoted at Q to a sector-shaped lever behind, which carries two weights, W W, to increase its downward bearing power. This weight-lever is loosely pivoted on the arbor, P, and turns solidly with the wheel when the brake is applied. There is a stop, S, to limit the descent, but it is in this case applied to the tail of the nipping lever. A connecting link, E, joins the nipping lever, L, to the see-saw. The internal position of the brake appears to have two advantages—namely, longer leverage around the fixed pin, making the feed more sensitive, and greater pro-

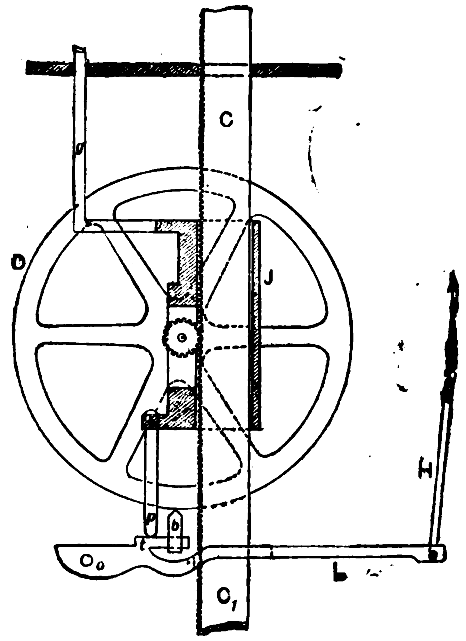

Fig. 19.—Brake-Wheel of Crompton-Cramp Lamp.

tection from dust and dirt. One peculiarity of the Brockie-Pell lamp is seen by reference to Fig. 6—namely, the device by which the core, B, of the shunt-coil is allowed a certain travel upwards before it pulls at the see-saw lever, its thinner part passing freely through a swivelled washer, *w*, on the see-saw. But the washer is of iron, and the core has an enlarged head, *h*. These adhere by magnetic attraction when the shunt-coil comes into operation.

Another very successful form of lamp is the Crompton-Crabb "double differential" (2539^{88}), shown as a whole in Fig. 18, and in detail in Fig. 19. In the lamp shown in Fig. 18 there are two carbon-rods, M and N, of which N comes first into operation, afterwards changing over. On each carbon-rod is cut a rack which drives a brake-wheel, or, rather, a pair of brake-wheels, one behind the other on the

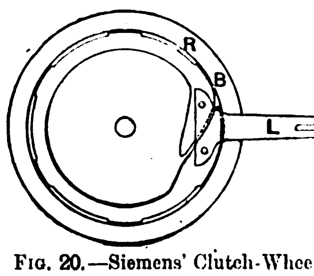

Fig. 20.—Siemens' Clutch-Wheel.

same pinion. The arbor bearing is not, as in the two preceding lamps, fixed in the frame of the lamp, but passes through a short sleeve or jockey, which, when the wheel is free to turn, can slide up or down on the carbon-rod, but is prevented from turning sideways by a guide pin, *g*, above. Below the brake-wheels stands a lever, L, pivoted at *o*, and attached by a link, H, to the core of the solenoid overhead. This lever carries a small table, *t*, and a brake-piece, *b*, faced with phosphor-bronze. When the lamp is out of action, the free end of the lever is down, and the weight of the wheels and the carbon-holder bears down upon the table, *t*, through a pin, *p*, which projects down from the jockey-sleeve. In this position the wheels do not touch the brake-piece, *b*, and are free. When the current is turned on, the main coil of the solenoid attracts its core, first drawing up the lever, which, turning on its pivot as it rises, brings the brake-piece against the rim of the brake-wheels and clamps it. Secondly, the wheels being thus prevented from turning, any further rise of the lever lifts the brake-wheel, jockey, and carbon-holder bodily (the weight of them all resting on the brake-piece), thus striking the arc. Thirdly, as the arc burns away, the lever again descends, until, fourthly, when the tail-piece rests on the table and takes the weight off the brake, the feeding begins. There are many other points of interest about this lamp which cannot here be discussed.

Digitized by Google

Other forms of brake-wheel have been used with success, notably an elastic band-brake, resembling Appold's well-known device, applied outside a smooth wheel, in Statter's lamp (2985^{86}).

The most recent form of clutch-wheel is that devised by Alexander Siemens, 6987^{87}, illustrated in Fig. 20, The lamp to which this device is applied is a holophote lamp for search-lights, with a screw-feed, the screw being turned by this clutch-wheel. It is about one inch in external diameter, and has a projecting rim, R, within which lies an internal metal ring, B, slightly sprung outwards, and cut obliquely, somewhat in the manner of the elastic metal packing-rings used in engine pistons. The two ends of this internal split ring are joined, by two pins, to a small lever, L, which projects outwards. When a reciprocating motion, of either large or small range, is imparted to the forked end of this lever, this internal clutch alternately bites against the rim and pushes it forward, and then releases its grip and draws back. This device constitutes a true positive feed.

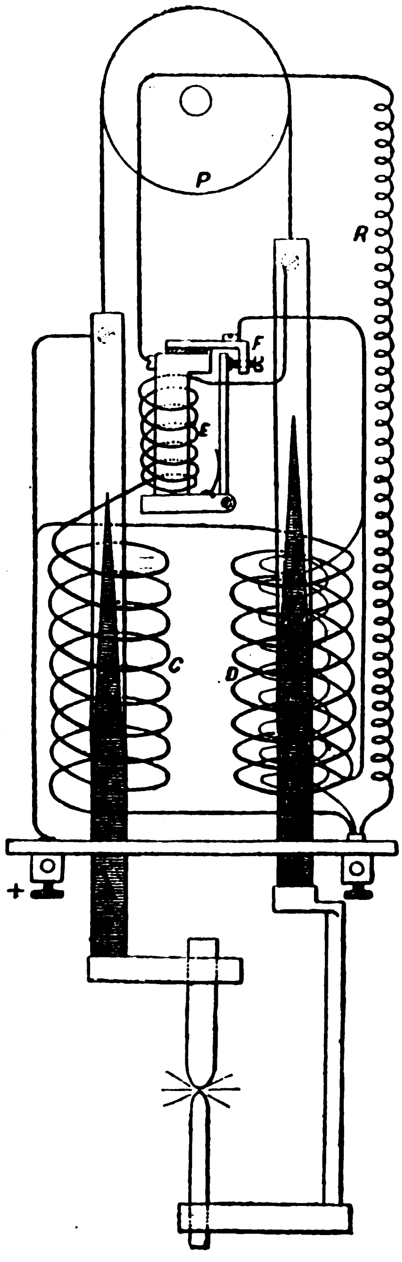

FIG. 21.—Pilsen Lamp.

The same device reappears in a recent lamp by Fein (1888), which has a main circuit-magnet striking the arc by drawing down the lower carbon, and a shunt-magnet for feeding, which vibrates an armature by make-and-break arrangement. The upper carbon-holder is smooth, of rectangular section, with a smooth feeding-roller firmly pressed by a spring against it. This feeding-roller is attached to a clutch-wheel like Fig. 20. The lamp will work even upside down. Unlike the clutch-wheel devices previously described, Fein's feed is non-retractile. The latest patterns of clutch-wheel feeds are those of Mackie (7184^{87}) and Mathis (10740^{87}). The advantages of the clutch-wheel mechanisms over the clutches that act directly on the rods, may be summed up by the remark that they render the operation of the lamp independent of dust and dirt.

Of lamps with *screw-feed* motions the most recent are the projector lamp of Siemens (6987^{87}) mentioned above, and a motor lamp by Maquaire, which is now being used at the Kensington Court lighting station. In the latter an ingenious and simple method of reversing the motion of the motor armature is adopted, so that both striking and feeding are accomplished by the same screw.

The class of lamps in which cord and pulley mechanism is employed in conjunction with a long range open solenoid, goes back to the early examples of Archeran and Jaspar. In the more complex Pilsen lamp (Krizik and Piette, 1397^{80}) two solenoids are used, each with its own coned core, the plungers being connected by cord and pulley, and each bearing one carbon pencil. The arrangement of the circuits of the recent form of lamp is shown in Fig. 21, the core, A, being drawn into the main-circuit solenoid, C, to strike the arc, whilst the differentially-wound solenoid, P, varies its pull on the core, B, according as the carbons are required to approach, to stand still, or to recede, the former action occurring when the shunt current prevails. The special cut-out mechanism, E F, will be alluded to later.

(*To be continued.*)

PHYSICAL SOCIETY.—March 23.

Prof. REINOLD, President, in the Chair.

The following gentlemen were elected members: Sir James N. Douglas, Sir Douglas Galton, Messrs. C. H. W. Biggs, C. Capito, A. C. Cockburn, R. E. Crompton, J. M. Gorham, G. C. Gümpel, W. H. Massey, E. Moynihan, F. J. Mudford, R. W. Paul, and C. E. Spagnoletti.

Prof. J. V. Jones read notes **"On the use of Lissajous Figures to Determine a Rate of Rotation, and of a Morse Receiver to Measure the Periodic Time of a Reed or Tuning Fork."** In determining resistance absolutely by the B. A., or by Lorenz's method, it is important to know the speed of rotation at the instant when the deflection of the galvanometer needle is observed. To determine this, an arm carrying a mirror is caused to oscillate by a pin placed eccentrically in the end of the spindle, and a Lissajous figure is obtained by using another mirror mounted on a vibrating reed driven electrically. Equality of period is obtained when the resulting elliptical figure is permanent, and the frequency of the reed is determined subsequently. In making the experiment it is found convenient to control the speed of the disc by breaking it, either with the finger or a piece of wood. The reed consists of a rectangular steel rod 100cm. long, and section 1·51 × ·60cm., and the length of the vibrating segment can be altered by sliding it through a clamp. To permit of this change without altering the electrical contacts, the latter are formed by two independent springs, one of which is always in contact with the rod. For determining the frequency of the reed, a second pair of contacts are operated by the vibrator, and the currents recorded by a Morse receiver, whilst simultaneously the paper receives marks from a pen controlled by a standard clock. The limit of accuracy of this part of the experiment is found to be $\frac{1}{10}$ per cent. due to changes in the reed's frequency. This is a serious defect, and the author of the paper asked for advice as to the precautions necessary to obtain reeds of constant pitch. **Prof. Ayrton,** whilst recognising the extreme importance of determining speed accurately, suggested that the inconstancy of the reed may be due to the impulse being given at the end instead of at the middle of its swing, and recalled an experiment shown before the society by Prof. Perry and himself, in which the pitch of an electrically-driven fork was varied greatly by altering the adjustment of the contact screw. Referring to Dr. Thompson's modification where two tuning-forks drive each other, it was pointed out that the method requires the synchronism of the two forks to be very exact. **Mr. Blaikley** enquired whether any doors were opened or closed during the experiments, as the pitch of a reed is affected by the size of its resonance chamber. He also stated that the pitch of reeds driven pneumatically could be maintained constant to the part in 10,000, and mentioned that two forks nearly in unison influence each other's period when near together. Referring to the two forks mentioned by Prof. Ayrton, **Prof. S. P. Thompson** said it was advantageous to mount such forks on sounding boxes, for when placed at a suitable distance apart they then exert considerable mutual control. The sketch put on the board by Prof. Jones led Dr. Thompson to suppose that a perfect method of driving forks had been devised, for two springs were shown touching opposite sides of the bar, and such an arrangement might be used to complete the circuit only when the reed is in the middle position. He also believed that forks give greater constancy than single reeds, and mentioned some recent improvements in which one prong of an electrically-driven fork is made of phosphor-bronze. **Mr. T. H. Blakesley,** reasoning from ideas suggested by Mr. Stroh's experiments on vibrating membranes, concluded that the periods of forks placed at ¼ wave length apart would not uninfluence each other. In reply to a question from Mr. F. G. Smith, **Prof. Jones** thought there could be no "creeping" of the reed through the clamp. He also stated that he had been led to use a reed from the results obtained in Delaney's system of telegraphy, and the fact that Lord Rayleigh considered electrically-driven forks satisfactory.

Dr. Hofford read extracts from the following papers:

"On the Clark Cell as a Source of Standard Currents," by Prof. R. Threlfall and Mr. H. Pollock. The authors find, contrary to ordinary ideas, that Clark cells can be used to send currents of considerable magnitude without the E.M.F. being appreciably changed, and have constructed cells which give ·001 ampere steadily for half an hour. This result has been obtained by increasing the size of the cell so that each electrode is about five square inches in area, and the internal resistance is about six ohms. For the ordinary small test tube cell, the resistance of which may be about 1,500 ohms, the current ought not to exceed ·00001. On closing the circuit the P.D. (potential difference) drops almost instantaneously to its steady value, and when the circuit is opened, rises equally rapidly to very nearly the original E.M.F. The cells completely recover in time. If the current sent be too large, the P.D. falls for a time, and afterwards rises and tends towards a fixed value. In this respect, Clark's cells are greatly superior to large Daniells sending current through the same resistance. The paper contains several tables and curves, as well as valu-

Digitized by Google

able results respecting the close agreement between the E.M.F.'s of a great number of different cells.

"On the Application of Clark's Cell to the Construction of a Standard Galvanometer," by Prof. R. Threlfall. A large cell as above mentioned, together with a known platinoid resistance, are used to standardise a reflecting galvanometer, constructed with a single movable coil sliding in guides so as to vary the constant in known proportions. Two controlling magnets are carried on opposite sides of a sleeve sliding on a central tube enclosing the long fibre, and a small hollow copper cylinder in oil acts as damper. The tangent law was found by calculation to be practically correct up to 15deg., and the scale is curved so as to read tangents on a scale of equal divisions. To give this result, the approximate polar equation to the curve is shown to be $r = f\ (1 + 207\theta^2 + \cdot 0269\theta^4)$. In standardising the instrument, a known current is sent through it from the Clark cell, and the controlling magnets adjusted till the spot comes to a fiducial mark on the scale. By varying the position of the coil, currents ranging from 001 to ·4 ampere can be measured.

"On the Measurement of High Specific Resistances," by Prof. Threlfall. The chief points dealt with are the means for producing thin plates of material of known dimensions, the form and methods of magnetising the needles, and the arrangement of suspension found necessary when great sensibility is required. For producing the plates, two plane platinised brass slabs are used and kept at a known distance apart by micrometer screws, whilst the material is melted between them. The screws are then withdrawn, and the resistance determined by comparison with a megohm, using different E.M.F.'s in the two cases so as to obtain about equal deflections. As regards the galvanometer, after many unsatisfactory attempts to use one made according to the Messrs. Gray's pattern, the coils of that instrument were mounted in the ordinary way, and used with an astatic combination of magnetised steel discs. Extreme care was taken to obtain discs exactly similar, and a pair of electromagnets were made to magnetise them *in situ*, so as to obtain great astaticism. For suspending the magnets, quartz fibres were found greatly superior to silk, the zero of the instrument being very indefinite even with a silk fibre 30in. long. Considerable difficulty was experienced in attaching the mirror to the needle on account of the distortion produced by ordinary cements ; a slow-drying white paint was ultimately used and found satisfactory.

"On the Measurement of the Resistance of Imperfectly Purified Sulphur," by Prof. Threfall and Mr. A. Pollock. The apparatus used is described in the previous paper, the galvanometer of 16,000 ohms being arranged to give the division for 2×10^{-12} ampere. A mean of the results obtained gives about 11×10^{13} ohms per cubic centimetre as the specific resistance. In performing the experiments many precautions were required to prevent air current and magnetic disturbances, and paraffin keys were found to give much better insulation than ebonite ones. In conclusion, the authors enumerate the chief points to which attention should be paid in designing and using very sensitive galvanometers. They consider it desirable to use quartz fibres at least 6ft. long, to provide very fine adjustment for the controlling magnets, whose supports should be independent of the suspension arrangement, and believe the whole should be placed in a thick soft-iron cylinder. **Mr. Boys,** speaking of attaching mirrors to wires, said he found a very small speck of shellac varnish to be very satisfactory. As regards quartz fibres, Prof. Threlfall's method of producing them differed materially from his, and the fibres were much thicker. He considered it quite unnecessary to use fibres anything like 6ft. long, and thought 15in. quite sufficient where the weight to be supported was not large. **Prof. Ayrton** regarded the results obtained from Clark's cells to be of extreme scientific and commercial importance, for they showed that a very convenient standard of E M.F. could also be used as a standard for current. **Prof. Thompson,** after commenting on the convenience of good E.M.F. standards, expressed a hope that Prof. Threlfall would be able to suggest a convenient method for producing a standard ampere.

COMPANIES' MEETINGS.

SUBMARINE TELEGRAPH COMPANY.

An extraordinary general meeting of this Company was held on Monday at the offices, Throgmorton-avenue, London-wall, to consider and decide as to the offer of Her Majesty's Government and the Government of France for purchasing the Company's cables.

Sir Julian Goldsmid, M.P., who presided, stated that on the 16th of July, 1878, they made an agreement with Lord John Manners, who was then Postmaster-General, which, besides providing for giving to the Post Office the proportions of the receipts which were derived from telegraphic communication with the Continent, also contained this important clause : "This agreement shall take effect from the 1st of January, 1879, or so soon after that date as the French and Belgian Governments shall have granted a renewal of the concession to be applied for, and shall remain in force until the 31st of December, 1898, but no alteration of the existing tariffs shall take place unless and until this agreement shall come into operation." His predecessor, the late Sir James Carmichael, forthwith applied to the French Government to give them a renewal or extension of the concession, which would expire early in the present year. The French Government, however, on that occasion, and for three succeeding years, refused to grant the request, alleging that the application was premature. So matters went on until three years ago, when he decided on making a determined effort to put the agreement referred to into force. The Directors had negotiated with four successive Ministries, and three of them nearly came to a conclusion. The last Ministry they negotiated with was that of which M. Rouvier was the head, and he informed the Directors in writing that he was prepared to grant a renewal of the concession for ten years. On the part of the British Government, however, a diplomatic note was then forwarded to the French Government requesting the latter not to renew the concession. The Directors contended that under the agreement Her Majesty's Government had no right to make such a request, but the argument of the Government was that, as a reasonable time had elapsed since the agreement was signed and no renewal of the concession had been obtained under clause 8, they were no longer bound by an agreement which had not been put into force. The policy of Her Majesty's Government had changed, and they had determined to make arrangements by which all the telegraphic communications between this country and France, Belgium, Holland, and Germany should be in the hands of the respective Governments. The Directors considered that this decision, in view of the agreement in question, was extremely hard upon the proprietors in the Company. The Government then made arrangements with the French Government for jointly acquiring the cables between France and England and Belgium and England. The Directors had had frequent interviews with the Government, who had been requested by the French Government to carry on the negotiations on behalf of all the Governments concerned. The sum and substance of the proposals made by the Chancellor of the Exchequer and Mr. Jackson (of the Treasury) was originally that the Company should sell the French and Belgian cables at a valuation price, the valuers being appointed by the Governments and the Company, with an arbitrator, as usual, in case of disagreement. The Directors regarded this proposal as satisfactory, but, to their surprise, about three months ago they were informed that the French Government would have nothing to do with such a method of valuation, and that some other system must be adopted. Troublesome negotiations followed, it being finally decided that the Government should appoint officers to test the cables and ascertain their electrical condition, and that an offer should then be made to the Company. The result of the testing had been that allegations had been made that the cables were patched cables, and that the officer did not consider them to be in electrical condition. The Directors had pointed out that the cables did the work well, without any impediment to the traffic, and that from a business point of view they were therefore in perfect condition. [At the request of the Chairman, the Secretary then read the correspondence between the Company and the Post Office.] Continuing, the Chairman said that the Governments had offered for the four French and the two Belgian cables £22,330, or practically about 25 per cent. of the cost of laying new cables, whereas the Directors had calculated that by the worst terms of a valuation, with recourse to an arbitrator, as originally agreed to by Her Majesty's Government, the Company would receive at least 50 per cent. of the cost of laying new cables. The French and Belgian cables earned in the past half-year about £40,830, and deducting £17,000 roughly for working expenses, a net revenue remained of £23,830, or a little more than the price offered to the Company for earning it. From what he had stated the proprietors would understand that the Directors had been placed in a most difficult position. Two other cables were left to them, which were leased to other companies. If they refused the offer that had been made to them, the Governments might say that they would not have the cables at all, in which case they would only be worth their picking up value—a point which the proprietors must carefully weigh. He suggested that they should pass a resolution to this effect : "That the Directors be requested to inform the Government that, in the opinion of the shareholders, their offer of £22,330 for the purchase of the Company's cables between England and France, England and Belgium, and Jersey and France is far below their value ; that the Directors be authorised to allow the Government to work the cables on and after the 1st of April next, to continue their negotiations, and to conclude the sale of the cables to the Government at the best price they can obtain, and that the Directors inform the proprietors by circular as soon as possible of the result of their further negotiations." In his opinion, and in that of the majority of his colleagues, that was the course which it would be advisable to take. The British Government, he might point out, were taking over a great deal of property which did not concern the French Government in any way.

A discussion followed, in the course of which several shareholders strongly animadverted on the course which had been taken by the British Government.

Mr. Lewis seconded the motion.

An amendment was proposed for adjourning the meeting until Thursday, but, on a show of hands being taken, the amendment was lost, and the original motion was carried.

Resolutions were afterwards passed for winding up the Company voluntarily, and appointing Sir J. Goldsmid, the Hon. H. R. Brand, and the Secretary liquidators.

DIRECT SPANISH TELEGRAPH COMPANY, LIMITED.

The thirty-first ordinary general meeting of this Company was held on Monday at Winchester-house, Old Broad-street.

Sir James Anderson presided, and in moving the adoption of the report stated that in the half-year ended December 31 last they had carried 2,000 more messages, which, however, were composed of 27,000 fewer words. They were face to face with the natural desire of all merchants to make their telegrams as short as possible. An enormous number of messages to the East consisted of only three or four words, and a three-worded message did not pay at all. There had been a decrease of £305 in the traffic receipts compared with those for the corresponding period of 1887, the reduction being owing to the failure of the fruit trade—a circumstance which would have been more serious for them a few years ago, when the messages carried by them were all about

Digitized by Google

fruit and shipping. Since the commercial treaty was framed the messages had been of a more miscellaneous character, and their traffic was a growing and a sound one. Since the date to which the report applied a break had occurred in the Bilbao cable. Fortunately, the Eastern Telegraph Company had a ship at Lisbon, and, in spite of very bad weather, the repair was effected in 16 days. Notwithstanding this interruption, during which they lost some traffic—though not all, owing to the joint-purse arrangement with the Eastern Company—the receipts for the current quarter had exceeded those of the corresponding period of 1888 by £250.

Mr. Edward Etlinger seconded the motion, which was unanimously adopted.

Resolutions were afterwards passed declaring dividends at the rate of 10 and 4 per cent. per annum on the preference and ordinary shares respectively, and re-electing the retiring Directors and Auditor.

NEW COMPANIES REGISTERED.

Bath Electric Light Company, Limited.—Registered by Shaw and Blake, Doctors'-commons, with a capital of £25,000 in £10 shares. Object: to adopt and carry into effect an agreement dated March 8th, 1889, made between C. J. Wharton, F. J. Down, and A. F. Davies, of the one part, and J. Chivers, on behalf of the Company, of the other part, being an agreement for a license to use and work the Thomson-Houston system of electric lighting in the City of Bath, and within a radius of five miles. The first subscribers are:

	Shares.
Major-General J. Burn, 17, Lansdown-crescent, Bath ...	1
Major-General C. A. Benson, Ormond House, Bath	1
H. G. Massingham, Claremont, Oldfield-road, Bath	1
J. Chivers, 2, New Bond-street-buildings, Bath	1
A. Taylor, 8, New Bond-street, Bath........................	1
J. Ricketts, 26, Grosvenor, Bath	1
W. Jeffery, 2, Northumberland-buildings, Bath	1

The number of Directors shall be nine, or such smaller number, but not less than three. The first are Major-General J. Burn, Major-General C. A. Benson, J. Chivers, H. G. Massingham, and A. Taylor. Qualification: not less than 100th part of the subscribed share capital. Remuneration: £50 on every £5,000 or fractional part of £5,000 of share capital or debenture of the Company, provided a 5 per cent. dividend is first earned on the paid-up share capital.

Laing, Wharton, and Down Construction Syndicate, Limited.—Registered by H. F. Kite, 11, Queen Victoria-street, E.C., with a capital of £40,000 in £100 shares. Object: to acquire certain apparatus and articles, undertakings, and installations belonging to the business carried on by C. J. Wharton, F. J. Down, and A. F. Davies, trading as Laing, Wharton, and Down, in connection with the Thomson-Houston International Company's system of electric arc and series lighting. The first subscribers are:

	Shares.
P. G. B. Westmacott, Burwell, Newcastle-on-Tyne.........	20
B. H. Martindall, Everfield, Bickley.....	10
J. Tennant, Saltwell, Gateshead.............................	5
J. T. Merz, The Quarries, Newcastle-on-Tyne	4
W. Crewdson, 60, Courtfield-gardens, S.W.................	5
E. Waterhurst, 44, Gresham-street, E.C.	3
H. G. H. Norman, 5, Southwell-gardens, S.W.	5

C. J. Wharton, F. J. Down, and A. F. Davies, or other persons constituting the firm of Laing, Wharton, and Down, shall during seven years from March 1, 1889, be the managers of the syndicate. The said firm, so long as they act as managers, are to receive, by way of office rent and salary, £500 per annum, payable by equal monthly instalments of £41. 13s. 4d. and a yearly sum equivalent to 10 per cent. of the net profits of the syndicate in each year, but not exceeding £2,000.

PROVISIONAL PATENTS, 1888-9.

November 16.

16,681A. **Improvements in and relating to multiplex telegraphy.** Francis Jarvis Patten, 77, Chancery-lane, London. (Complete specification.) (This application, having been originally included in No. 16,681, dated 16th November, 1888, takes, under Patents Rule 23, that date.)

March 18.

4,722. **Improvements in coupling devices for electric conductors.** Henry Harris Lake, 45, Southampton-buildings, London. (Albert Clark Griggs, United States.) (Complete specification.)

March 19.

4,748. **Improvements in electrical and automatic appliances and methods for manipulating aeronautic balloon batteries in conjunction with aerostatic indicating, fulminating and fumigating repeating magazine batteries, and in shells for same, for the purposes of warfare.** Wm. Howson, Bank-buildings, Sheffield.

4,800. **Improvements in electric conductors.** Henry Harris Lake, 45, Southampton-buildings, London. (Alfred Austin Brooks, United States.) (Complete specification.)

4,821. **Automatic electric induction apparatus.** Louis de Stein, Arthur Podhorzer and Franz Haver Bachmann, 38, Chancery-lane, London.

March 20.

4,846. **Improvements in electric light fittings.** Charles Krauss Falkenstein, Emile Rousseau, and Conrad Krauss Falkenstein, 265, Victoria-park-road, London.

4,849. **Improvements in insulators.** Charles Vernon Boys, 11, Alexander-square.

4,875. **An improved system for electrical transmission of power for traction purposes by direct current.** Moritz Immisch, 52, Chancery-lane, London.

4,883. **Improved apparatus for showing whether an electrical switch or contact maker is on or off.** Frank Geere Howard, 36, Cleveland-street, Fitzroy-square.

4,889. **Improvements in the generation of power for electric lighting and its application to dwelling-houses and buildings generally.** Jules Cerpaux, 33, Chancery-lane, London.

March 21.

4,901. **Improvements in means or apparatus for use in conveying electric currents for lighting or other uses.** Rookes Evelyn Bell Crompton, 55 and 56, Chancery-lane, London.

4,954. **Improvements in electrical battery cases.** Hans Fowler Price, 53, Chancery-lane, London.

4,960. **Improved means for administering electricity to, and otherwise treating, horses and other animals.** Georgina McGuire Lawrance, 45, Southampton-buildings, London. (Complete specification.)

March 23.

5,063. **Improvements in instruments for the measurement of electric currents and electro motive force.** Emil Henri Hüngerbühler and Joseph Torr Todman, 21, Finsbury-pavement.

5,066. **Improvements in sockets or holders for incandescent electric lamps.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, Middlesex. (Alfred Swan, United States.)

5,084. **Improvements in electric clocks with synchronising mechanism.** Alfred Julius Boult, 323, High Holborn, Middlesex. (René Pouchard, France.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1888.

3,328. **Electric contact-makers, &c.** Langdon-Davies. 8d.

4,674. **Medical galvanic batteries.** Fry. 8d.

6,214. **Laying underground electric conductors.** Farquhar. 8d.

6,322. **Galvanic batteries.** D'Humy. 8d.

7,355. **Field telegraph conductors.** Treuenfeld. 4d.

16,048. **Secondary batteries.** Thompson. (Thompson.) 8d.

506. **Electrical switches.** Lake. (Law.) 11d.

759. **Electric railway switches.** Wells. 8d.

1,343. **Measuring electricity.** Nalder and others. 6d.

1,611. **Multiplex electric telegraphy.** Dewey. 8d.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended March 22 amounted to £5,670.

Globe Telegraph and Trust Company, Limited.—The Directors of this Company have declared an interim dividend of 3s. per share for the current quarter, payable on the 18th proximo.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Company, were £4,130.

Eastern Extension Telegraph Company, Limited.—The Directors of this Company notify a further dividend of 2s. 6d. per share, together with a bonus of 3s. per share, making a total of 6½ per cent. for the year 1888. The reserve fund has been increased by £66,101.

Humboldt Electric Power and Mining Company, Limited.—Certificates of shares in this Company are now ready for delivery in exchange for the bankers' receipts for payment of deposit, allotment, and first call, at the offices of the Company, 63 and 64, New Broad-street, E.C.

NOTES.

Personal.—Lord Sackville Cecil has joined the board of the Exchange Telegraph Company, Limited, as chairman.

Madrid.—A concession is being arranged for an electrical tramway of a length of three kilometres in this town.

Foreign Telegrams.—The Post Office announces that the telegraphic charge to Tunis and Algeria is reduced from 4d. to 3d. per word.

Havana.—It is announced that the electric lighting on a large scale is to be carried out in Havana. Satisfactory experiments have been made.

Paris Exhibition.—Amongst the names proposed for the technical advisers of the commission are those of MM. Hippolyte, Fontaine, Hospitalier, and Napoli. No decision has, however, been arrived at.

A Government Laboratory.—An electrical laboratory, under the control of the Government, is to be established in Berlin for the convenience of those of the public who desire to avail themselves of it.

Tenders for Electric Lighting.—The directors of the Exeter Theatre Company are inviting tenders for lighting the new theatre by electricity. Particulars will be found in our advertisement columns.

Tangier.—Dated Tangier, March 28, Reuter's Agency says: "The repairs required in the submarine cable are to be proceeded with immediately. It is not expected that any opposition will be offered by the Moorish Government."

The Telephone in Germany.—The German authorities have decided to establish direct telephonic communication between Berlin and Posen. The latter town will be connected up with all the principal garrison towns on the Russian frontier.

Civil Service Commission.—An assistant is required to the Professor of Chemistry at the Royal Military Academy, Woolwich. Particulars and forms of application may be obtained from the Secretary, Civil Service Commission, London, S.W.

A New Filament.—The Boston *Herald* learns that a Boston electrician has succeeding in making a carbon filament that will give 33 to 50 per cent. more light from the same current than the ordinary 16-c.p. lamp by its side in the circuit will emit.

Work in France.—By decree of the 19th February last, the President of the Republic has approved the contract made between the Mayor of Havre and MM. Ch. Mildé fils and Co. for the laying of electric mains in certain public thoroughfares of that town.

Santa Fe.—The telegraph lines of this province comprise 1,272 kilometres belonging to the Government, 562 to various municipalities, and 736 which are the property of private companies. There are also two telephone companies in Rosario with 2,013 kilometres of line.

Cuba.—The Municipality of Cárdenas, Cuba, have entered into a contract with the Compania Eléctrica de Cárdenas to install the electric light in fourteen streets and three public buildings. The Municipality are to pay 15,000 pesos in gold per annum for six years. At the end of that time the plant is to revert to them.

Electric Tramways.—Mr. Sellon, the engineer of the intended Chesham, Boxmoor, and Hemel Hempstead Steam Tramways, stated at a recent meeting of the Hemel Hempstead Highway Board that it was intended to commence the line between Hemel Hempstead and Boxmoor at once, and that portion of the tramway would be worked by electricity.

Harrow.—At the last half-yearly meeting of the Harrow District Gas Company, it was stated that the price of gas would be, from Lady Day, reduced 3d. per 1,000 cubic feet. It is only a simple arithmetic sum to find the amount saved by gas consumers owing to the reduction in the price of gas in various places when threatened with competition with the electric light.

St. Luke's.—At the St. Luke's Vestry meeting on Tuesday a letter was read from Messrs. Medcalf, of St. Mary-axe, stating that they were instructed by the directors of the London Electric Light Corporation to say they did intend in the present session of Parliament to proceed with their application for provisional powers with regard to their scheme.

Anglo-German Telegraphs.—On the 1st inst., the Anglo-German cables passed into the possession of England and Germany. Henceforth telegrams will be sent direct between the two countries over fourteen wires, and will be 25 per cent. cheaper—an advantage in which Austria-Hungary cannot share, as that country refused to join the convention.

The Electric Light in Spain.—A central station is about to be inaugurated at Ducango, in the province of Bilbao. The small town is to be lighted with 300 incandescent lamps. Similar projects are in view for the towns of Cestona, Azpeitia, and Azcortia (province of Guipuzcoa), where considerable hydraulic power can be utilised. Rumour is also busy with a scheme for central station lighting at Orense.

The Lighting of the City.—At the fortnightly meeting of the Commissioners of Sewers on Tuesday last, the Chairman said the Remembrancer (Mr. Goldney) had an important matter to bring before the Commission relative to electric lighting. Mr. J. V. Moore moved the communication be taken with closed doors, and this motion being carried, strangers were ordered to withdraw, and the discussion, which was understood to relate to the Board of Trade meeting on Wednesday, was taken in private.

The Electric Light and the Gas Companies.—A contemporary says: While the process of electric lighting is not so rapid as some enthusiasts had hoped, the possibility of its general adoption for domestic purposes is not overlooked by the managers of the great gas undertakings, and no efforts are spared to make rivalry an unremunerative venture. Three of the London companies are about to issue circulars offering to supply householders with all necessary fittings for the small payment of twopence per week until the whole is paid off.

Coast Telegraphs.—The Plymouth Chamber of Commerce has been pressing forward the very important project of girdling our shores with a continuous line of telephone and telegraph wires. The coasts of Norway, Sweden, Denmark, Holland, and France are already provided with a system of electrical communication, and it seem strange that we have taken no steps to do the same.

Digitized by Google

The Plymouth Chamber of Commerce estimates that it would only cost something like one hundred thousand pounds to connect all the existing stations with the nearest telegraphs.

The Tide Utilised at Last.—There is a curious water-wheel in use at Bowdoinham, says the *Electrical World*, probably the only one of the kind in existence. It is 27ft. in diameter, with a foot of its rim out of water at high tide; the spokes are wide and set diagonally, like the vanes of a windmill. It turns 18 hours a day by tide-power—running one way with the flow, the other with the ebb. With one foot fall of the tide the wheel is said to give about 50 h.p. Here is an hint, says our contemporary, for electrical engineers. The hint has been given often enough; we are glad to welcome its practical performance.

Animal Magnetism, or Suggestion.—Dr. Pinel, of Paris, has succeeded in hypnotising several subjects by means of the phonograph. All the commands given through this channel were as readily obeyed as those uttered directly, and "suggestions" of every possible sort were as effectually communicated through the medium of the machine as if made *viva voce*. The conclusion deduced by Dr. Pinel is that the theory of a magnetic current passing from the operator to the subject is entirely baseless, and that the real cause of the phenomena of hypnotism is nervous derangement on the part of those subject to them.

The Electrical Omnibus.—The electrical omnibus left the depot of the Ward Electrical Car Company, Limited, on the morning of the 2nd inst., at 9.30, and ran to Euston Station. Some of the directors and manager of the Liverpool Tramways Company were awaiting it, with Sir George Baden-Powell, M.P., and Mr. Houlding, the chairman of the Sanitary Committee of the Liverpool Corporation. The omnibus returned by way of Euston-road, Great Portland-street, and Regent-street, to the company's depot at James'-street, Haymarket. It came through the crowded traffic with perfect ease, and without exciting any alarm.

Coal Combination.—A correspondent to one of the gas contemporaries points out that the suggested coal combination would act disadvantageously towards the gas companies. He points out that they are endeavouring to develop the supply of gas for cooking and heating purposes as well as for lighting, and that all this progress in favour of coal consumption will be thrown out of gear by the combination. He acknowledges that they have two formidable foes to compete with, both of which are making considerable headway—viz., electricity and oil. We are glad to see such acknowledgment, and trust that the competition between electricity and gas will become considerably keener.

One Million Capital.—Rumour is again busy. We hear that Westinghouse is desirous of floating a company in London with a capital of £1,000,000. If such is the case, and we heard it on very good authority, it should bring its lesson with it. There is every appearance of a boom on the face of it, and unless Westinghouse leaves £250,000 of his own capital in the concern to ensure its bona fides, investors would do well to be cautious. We still hold to our contention that no competition over given areas should be allowed. Such a course is likely to end in disaster for all concerned, and once more sacrifice a deserving industry to the insatiable greed of the company-monger.

A Useful Publication.—We have received a work in pamphlet form by Belloc Luigi (G. Bruno and Co., Turin) entitled "Terminologia Elettrica," a vocabulary of electrical technical terms in Italian, French, German, and English. It is really a vocabulary of those technical phrases for which dictionaries are usually consulted in vain; and, as it is carefully compiled, it will be found of great use to those whose inclination or business lead them to peruse foreign technical literature. Its range of usefulness would, however, be extended if four editions were published, so that the four languages could be alphabetically arranged. It would then become a technical dictionary which could from time to time be amplified.

Testing-Room Practice.—It has always been understood that during the conduction of testing operations with low currents and sensitive apparatus, such, for instance, as cable-testing with an astatic galvanometer, the operator should stand upon some insulating substance, such as a sheet of vulcanite or indiarubber. It is now suggested by one who has had a great deal of experience in this direction that not only should this practice be departed from, but that the body of the operator should be effectively connected with an earth of small resistance. The chief reason alleged is that the human body accumulates charge accidentally received up to three or four microfarads, and is liable to very considerably disturb the electrical conditions of the testing circuit.

The Central Telegraph Office.—In the House of Commons, on the 27th ultimo, in answer to a question by Mr. Lawson, Mr. Raikes stated that the actual charge in respect of first-class telegraphists at the Central Telegraph Office for the current financial year could not yet be precisely stated, but it would be less than the estimate. Since the estimates of the expiring financial year were framed, an addition had been made to the establishment of the Central Telegraph Office, and the authorised number of the first class at the present time was 363. In this class of 365 persons there were on the 31st of January last 53 vacancies. To 34 of these promotions had been made within the last few days; and this, practically, was an answer to the petition of December.

O.S.A.—An ordinary general meeting of the City and Guilds of London Institute Old Students Association will be held on Wednesday, April 10th, at 7.45 p.m., at the Central Institution, Exhibition-road, S.W. (Committee meeting at 7 p.m.) The following paper will be read: "Photo-Mechanical Printing Processes," by W. F. Bourne, member. The paper is divided under the following headings: (*a*) Methods of producing intaglio plates; (*b*) methods of producing zinc or relief blocks; (*c*) photo-lithography; (*d*) Woodbury type; and will be illustrated by various specimens and blocks in various stages of production. The second number of the journal has been issued, and contains, besides other matter, Mr. Heller's paper on "Aluminium," and Mr. Albion T. Snell's paper on "Electromotors." In consequence of the rapid sale of this number a reprint has been necessary. Copies may now be obtained, price 7d. each, postage included.

Typical Cable Faults.—As affording some information relative to the behaviour of faults in submarine cables, the following note is not without interest: The fault was made in type C cable by the grapnel, while being raised to the bows, on the 5th of December, 1878, off Capes Villano and Finisterre. The depth varied from 100 to 300 fathoms. In hauling in the cable no strain was observed on the

Digitized by Google

dynamometer, but when the grapnel came to the bows it was found that a very few fathoms of cable hung upon it. The picked up piece tested as follows: End polarised more quickly with Z than with C, and showed a higher resistance with the negative current. The exposure was $1\frac{3}{16}$in. The lowest resistance, C to line was seven ohms. The lowest resistance, Z to line was 40 ohms, highest 200 ohms. The guttapercha was very much drawn. The conductor was broken off short; the ends clean and of uniform length. The sheathing was broken 6in. from end of core.

Electro-Deposition on Glass or Porcelain.—Recent experiments have demonstrated the possibility of depositing metals upon glass or porcelain by means of electricity. The process, which is ascribed to M. Hansen, is thus briefly described: "The great difficulty was found to be that of giving a conducting surface to the glass, because the medium, being no longer susceptible of removal once deposition had taken place, had necessarily to be of such a nature as not to weaken the adhesiveness of the deposited metal. The medium used is a solution of chloride of gold, or of platinum in sulphuric ether, which has received a sufficient quantity of sulphur dissolved in a heavy oil, to bring the whole, after being gently boiled, to a consistency which permits it to be painted on the glass, etc., with a brush. The plate is then slowly heated in a furnace until the sulphur and chlorine are driven off, leaving the gold or platinum adhering to the surface. The plate can then be treated in the ordinary manner.

The Electric Traction Company.—We are informed that there is absolutely no foundation whatever for the so-called "strange rumours" concerning the Electric Traction Company, Limited, and Messrs. R. E. Crompton and Co., Limited, of which the *Electrical Review* professes to have been "credibly informed." The Barking-road installation is now very nearly completed, and the cars have been running this week, and as soon as everything is in thorough working order, the regular service of the North Metropolitan line between Canning Town and Green Gate will be taken over, and worked entirely by electrically-propelled cars. Our contemporary's note was as follows: "*Strange, if True.*—There are strange rumours afloat respecting the position of the Electrical Traction Syndicate. First of all, we are credibly informed that a big company is about to be registered to work the system; and later we hear that Messrs. R. E. Crompton and Co., Limited, have taken the whole thing over. Which is correct? The same report was current respecting the almost defunct Elieson Company and Messrs. Crompton, so it is possible that the latest rumour has about as much truth in it."

Chelmsford.—The decision of Chelmsford is in favour of electric lighting. On the 25th February tenders for lighting by oil, gas, and electricity were considered by the Lighting Committee of the Council, which resulted in the committee recommending a contract with Messrs. Crompton and Co. for five years. This contract was for 20 arc lamps and 72 incandescent or oil lamps, subsequently modified to 110 incandescent and no oil, at a cost of £700 a year. The tender of the gas company showed a reduction of about £100 as against their price of last year, and it may be noticed here that the gas company has taken competitive action, and reduced the ordinary price of their gas by 2d. per thousand feet. The Council had this report before them several times, and some months ago decided to call a public meeting to discuss the matter. This meeting took place last week. After a somewhat stormy discussion, in which all manner of hard things were said about electric lighting, it being asserted that it was almost an entire failure, the proposition was carried "That this meeting is of opinion that the recommendation of the committee be carried out—viz., that the Council be requested to accept the tender of Messrs. Crompton and Co. for the public lighting of the borough." At the meeting of the Town Council on the Wednesday following this meeting, the question was again freely debated, and it was finally resolved to accept the tender of Messrs. Crompton and Co.

The Indian Telegraph Department.—The annual report of the Indian Telegraph Department during 1887-88 shows that a considerable increase took place during that year in the number of miles open, the number of messages sent, and in the receipts. The most important event was the transfer to the department of the Indo-European Telegraph Department. The Indo-Siam route is said to have proved almost valueless. The total length of line open at the end of the year was 93,743 miles, representing 93,517 miles of wire and 226 miles of cable. During the year there was an increase in the total length of 6,657 miles, representing 6,627 miles of wire and 30 miles of cable. A large portion of the wire lines are worked by railway companies, there being no less than 33,043 miles of wire in connection with the various railway systems, and much of the increase in the total length of line noticed above was caused by the opening up of new lines or the extension of existing ones. In Burma, the work has mainly consisted in consolidating and strengthening existing lines. Communication between Upper Burma and Assam has been established by the completion of the line from Manipur *viâ* Tammu and the Chindwin Valley. This line runs from Mandalay to Ava, where a cable crosses the Irrawadi and connects it with Sagain. From thence it is carried across country *viâ* Myinmu to Moniwa, where it meets the Chindwin, and follows the valley up to the junction of the Yu river, after which it follows that river to Tammu. The connection of Upper Burma with India by this route has been attended with considerable difficulty, and the staff employed suffered much from hardship and exposure, which brought on fever and malaria.

Brussels.—The programme for the organisation of a system for the distribution of electricity, adopted by the Common Council of Brussels at a meeting held on the 25th ult., is briefly as follows: Proposals will be received up to the 1st of next July for the establishment and carrying out of a system of electrical distribution, by underground mains, for lighting purposes, for motive power, and other applications of electricity. The competitors will be required to formulate their proposals in such manner as to assure for the first installation at least 10,000 16-c.p. lamps in an area mentioned in the proposal. It should also be stated upon what terms competitors are prepared, should the Council so desire, to extend the lighting beyond the limits laid down. The concession will be for a maximum period of 18 years, but the Council reserve the right to take over the installations after three, six, or nine years, as well as after the expiration of the concession. The terms should be distinctly stated for each one of these periods. The price per 100 watts-hour must be given for (1) private lighting and (2) public lighting generally. Other conditions are, the amounts of the rental to be paid to the State and the caution money to be deposited. The proposals must be

Digitized by Google

drawn up in the clearest possible manner, indicating all the conditions upon which intending competitors are willing to accept the work. The two following clauses should be inserted: The authorities shall at all times have access to the establishments of the concessionaire; the contractor shall be deprived of his concession if it be decided that the work done by him is not efficient. Judgment upon this point to be passed by three experts; one nominated by the Council, one by the contractor, and the third by the President of the Tribunal of the First Instance.

Electric Light in Germany.—The following list of towns in Germany lighted by electric light is given by the *Bulletin de L'Electricité*, and illustrates the progress made in central station lighting in that country. Over 16,000 h.p. is employed in these stations, more than half of which is for Berlin alone:

Towns.	System.	h.p.	Mains.
Barmen	3-wire and accumulators	600	underground.
Berlin:			
Markgrafenstrasse	„	3,900	„
Mauerstrasse	„	2,000	„
Spandaustrasse	„	2,000	„
Dorothienstrasse	„	2,000	„
Brunswick.	„	2,000	„
Bremen	3-wire	600	„
Breslau	„	500	„
Cologne	„	500	„
Darmstadt	3-wire and accumulators	450	„
Dresden	„	500	„
Eberstadt	„	100	„
Elberfeld	3-wire	325	„
Ems	multiple series	100	overhead.
Frankfort	„	1,000	„
Gorlitz	„	450	„
Halle	„	550	„
Hamburg	3-wire	1,200	underground.
Königsberg	„	300	„
Lübeck	„	300	„
Majbeburg	„	500	„
Mulhausen	„	300	„
Olmütz	„	300	„
Strasburg	„	400	„

A large number of these stations have already begun considerable extensions to their plant in addition to these figures. It is noticeable that not one of these stations uses the alternate current system, and that nearly all the mains and feeders are placed underground.

Ship Lighting.—Messrs. W. H. Allen and Co., of York-street Works, Lambeth, have just completed the lighting of a large passenger vessel, built by Messrs. Laird Bros., Birkenhead, for the Compania sud Americana de Vapores. The vessel, named the "Imperial," is one of 2,000 tons burthen, propelled by engines of 4,000 h.p., and is specially built for the trade between Callao and Valparaiso. The boat is fitted with the most modern appliances, and the saloon is lined with maple and satinwood, beautifully ornamented with carvings, and luxuriously upholstered. The electric light has been provided for every part of the ship from the masthead to the coal bunkers, and employs over 230 glow lamps of the Edison-Swan type. The signal lights are considerably stronger than can be provided by the best oil lamps, and are so fitted that oil can be substituted, if needful, at a moment's notice. Special brackets are provided for loading purposes. In the engine-room, bunkers, and holds plugs have been inserted so that the current may be tapped, and a powerful light concentrated in any given spot for temporary purposes. The elegant electroliers for the saloon and social hall have been designed to suit the fittings and furniture, and are adapted both for oil and electricity. The lamps exposed to rough usage are enclosed by damp proof bell glasses, and these are protected by strong wire cages. Cockburn's slate switches and fuse-boxes have been used throughout, each state-room being separately connected. The conductors branch into six circuits from a six-way slate switchboard, and a second board, with the main fuses, and fitted with a voltmeter, is placed on the return circuit. All the wires are enclosed in wood casings. The "Kapp" dynamo is compound-wound, and capable of feeding the whole of the lamps at the low speed of 280 revolutions per minute. It is driven direct by an Allen twin engine, at a steam pressure of 160lb. The engine and dynamo are so fitted as to work without vibration, and no sparks are visible at the brushes. The installation has been superintended throughout by Messrs. Allen's electrician, Mr. J. W. Kempster, and gave universal satisfaction on the trial.

Printing by Electricity.—As has already been remarked, a new departure has been taken in the printing of newspapers, which we think is likely to be largely adopted in the future. On Saturday before last the formes of the *Star of the East* (the evening edition of the *East Anglian Times*) were placed on the Wharfdale machine, which had been geared to a motor in connection with 50 E.P.S. accumulators. The *East Anglian Times* says: The current from the batteries was turned on and the motor at once began to revolve rapidly. A belt from it drove the printing-machine just like a steam-engine, but instead of an engine with a great flywheel, occupying a considerable space, the whole electric motor was not bigger than a barrel churn. Its driving pulley was only 9in. in diameter. There was no smoke and no noise, no need of a man to attend to it. Yet the power generated was ample, and directly the handle of the Wharfdale printing-machine was turned copies of the *Star* began to fly off with great rapidity. All the machines in the room—two printing and two folding—were, for a trial, run simultaneously by electricity, and went at a rattling pace. It was curious and instructive to change from this noisy scene to the small storage room at Messrs. Laurence, Paris, and Scott's central station, where the batteries did their invisible work. There seemed to be a moral lesson about the experiment, that the noisiest agents are not always the most potent. In London and all places where room is valuable, electrical motors would possess many advantages over steam. The whole apparatus can be contained in a closet, dispensing with cumbrous engine, boiler, and chimney-shaft. Then, again, no time is lost in getting up steam, but an immediate start can be made, and directly the work is done a knob is turned and the current from the central station cut off. For intermittent work electric motors must, therefore, be admirable and economical. There are occasions again, rare no doubt, when the use of steam is itself impossible. On the breaking-up of the frost a fortnight ago the main of the Ipswich Water Works burst, and about midnight our engine-driver arrived with a woeful face to tell us that the printing would probably have to be stopped for want of water. Electrical power in reserve would in such, and many another, emergency be of great value to the printer of daily papers, who cannot afford to wait a minute. A breakdown to him of a few minutes is equivalent to the loss of a day. The credit of the performance, which is simplicity itself, says our contemporary, belongs to Messrs. Laurence, Paris, and Scott, and to their Ipswich manager, Mr. Sisling.

ELECTRIC WIRING OF BUILDINGS.*

BY J. D. F. ANDREWS.

The first points for consideration in devising a wire system for electric lighting are, what contingencies will be met with that will affect the system, and what faults will arise in it after its introduction.

Throughout past experience it has been found that the practical pressure of electricity for electric lighting is, within 50 per cent. either way, about 100 volts—the 100 volts being most generally adopted. The chosen conductor is copper, and the most widely adopted insulation is indiarubber in many modified forms; the insulated conductors are usually protected and held in position by wooden casing. We need hardly question the object of the conductor, but what is the object of the insulation? The conductors if held in good dry wood casing only would be protected from interference. Its object is to meet one of the worst contingencies—moisture or water—which is an ever working evil on electric light wires. If you place a copper wire in water with electricity passing along it, the copper will be removed electrolitically from the part of the wire where the electricity enters, and deposited where it leaves. The same process goes on where uninsulated or badly insulated electric light wires lie in water or surrounded by moisture. Even though no electricity is flowing through a copper wire exposed to moisture and the atmosphere, it is acted upon chemically. The result of the electrolitic and chemical actions on electric light wires is to thin them and make them insufficient for carrying the current, and consequently they become heated. Or the result may be that the wire is eaten through when an electric arc is produced. This effect or fault is called an opening circuit, and is about the most difficult and dangerous fault to contend with. It is usual to lay the electric light leading wire in a groove in the casing neighbouring and parallel to the return wire. Water often saturates the casing between them, and when the insulation is poor, the electricity will pass through the moistened wood and char it, often setting it in flames. Faults such as this where a great leak is taking place between the wires are called partial short circuits, and are equally difficult to avoid and as dangerous as opening circuits. The study of the insulation of the wires is therefore obviously of great importance. Most of the results in good insulation were obtained by telegraph engineers before the electric light business was started, but in the new businesses these results were almost entirely ignored. Great insulation was then not considered necessary. Special covering for the wires was devised of a cheap and poor quality, which, it is greatly to be regretted, has continued in use by many contractors to the present day. As previously stated, indiarubber is the base of the insulation of most electric wires, the purer the material the better the insulating properties; but pure indiarubber is easily influenced by air: at first it gets hard, and in course of time changes to a soft, sticky state, when it is useless as an insulation. Pure indiarubber is still the foundation of insulation on the wires, but in the very best qualities it is protected from the atmosphere by an outer coating of what is known as vulcanised indiarubber. Such qualities of insulation consist of first one or two lappings of pure indiarubber, then a layer of indiarubber mixed with such minerals as soapstone, over which again is laid a coating of rubber mixed with a large proportion of sulphur. The wire, with its three coatings, is now subjected to a high temperature in a vulcan by means of steam, through which the rubber and sulphur combine, while any surplus is absorbed by the middle coat, which is called the separator. Such is the insulation of the best quality wires; the inferior qualities and those most generally used are insulated simply with pure rubber and cotton serving, with ozokerite or other compound tape laid together in many different ways, according to the device of the makers. The compound tape is supposed to protect the pure rubber from the air, but it only plays this function to a small extent. The usual reliable life of such wires is from two to three years, and not being reliably waterproof throughout their length, at any time there is always danger of failure through moisture. Vulcanised indiarubber covered wires of the class above described—there are many inferior kinds—is perfectly reliable in water or air for a great number of years. The next contingency that has to be contended with is mechanical damage. The wires being more or less flexible and the covering soft, they are easily damaged. This difficulty is usually met by casing the wires in wood, and it being necessary to employ two conductors for electric lighting—the casing has two grooves, one for each conductor—a cover being fixed over them. Wood casing has the disadvantage of harbouring moisture. Another method of protecting the wires is that of sheathing them with an outer covering of wire as introduced by the writer some years ago in ship lighting. This method protects the wires much more effectually than casing and does not harbour moisture. Iron pipes have been used in many cases, and are an excellent protection; but moisture collects in them, and if there should be a fault in the insulation, it is sure to find it. There is another fault besides the opening circuit and partial short circuit not yet touched upon—namely, a dead short circuit, or a direct contact between the opposite conductors. This is the most frequent fault, and if it were not that there is a simple appliance called a fuse to meet it, it would also be the most dangerous fault. Short circuits usually happen in the fittings where the opposite conductors are necessarily brought nearer each other, and at these points the insulation is generally much thinner and poorer. Short circuits also often happen where the wires cross, and frequently by contact with gas or water pipes, which make very complicated faults because the two wires usually touch the pipes a distance apart, which will be better understood by reference to Diagram 1. Suppose the current to leave the dynamo by the positive wire, pass to the lamps by the branch wire and back by the negative branch wires through the fuse, F, and the negative main to the machine. Suppose now the positive branch becomes connected to a gaspipe at, say, A. This would not indicate itself in any way, and the installation would of course continue working just the same until the opposite wire got connected to the gaspipe, say, at B. Now the current will become excessive, more than the branch wire can carry without getting dangerously hot, before the main fuse, T, melts. In the above description it is assumed there is a safety fuse at F, but it will be observed the short circuit has bridged the wire in which it is inserted, and it is consequently useless to avoid the excessive heating of the wires with such faults above referred to. It is necessary to have fuses, one on each wire, such as at F and S. Under such circumstances, when a short circuit, such as described, between A and B takes place, the fuse, S, would immediately blow and prevent danger. Let us again assume there are fuses on only the negative wires, we will see there might have been even a worse fault. Again, supposing a connection at A with the gaspipe, which is, of course, connected to the earth, we will assume the second connection to take place in the dynamo field-magnets at C. The current will now traverse the positive wire to A, thence to the gaspipe to earth, and back to the dynamo. This route is a short circuit, and one, moreover, that bridges both branch and main fuses, which we have assumed to be only on the negative wire, as is still the practice of some contractors. The consequence of this short circuit is similar to the one from A to B, but worse, because there are no fuses at all left to protect the system. Of course, with another main fuse on the positive wire, such a short circuit could not continue. There is, however, objection to the multiplication of fuses. They are a danger themselves sometimes, such as in the case of a partial short circuit that does not increase the current sufficiently to melt the fuse, but quite sufficient to heat it to a degree dangerous to any inflammable material in the neighbourhood; and it may continue in this condition some little time before it fuses, especially if it is a large one. Another point of danger from a fuse is when it melts it throws out sparks of molten metal. Of course, it will be said that the evils in fuses can be reduced by proper construction. That is true; but it is decidedly better to avoid, if possible, numerous points of danger in an installation resting on special construction or the care of an attendant for their prevention. We will consider later how this to a certain extent can be

* Paper read at the Philosophical Society of Glasgow.

Digitized by Google

achieved. In the foregoing we have considered mainly the contingencies or dangers arising with the introduction of electric light into buildings, and we may summarise the main points as being an opening circuit, a partial short circuit, a dead short circuit, and the fuses. We have considered the dead short circuit to be met by the fuse, although a new element of danger is introduced, which, however, is much less in degree. This new element of danger can be reduced to one-half by connecting one of the leading wires—say the positive to the earth and the gas and water mains, it being only on account of the latter that it is otherwise necessary to provide a fuse on each wire. Diagram 2 will show this more plainly: The current leaves the dynamo by the positive terminal, and meets at once a connection to earth, and the gas and water mains then proceeds by the positive wire to the lights and back to the dynamo. This connection to earth is wilfully effecting the

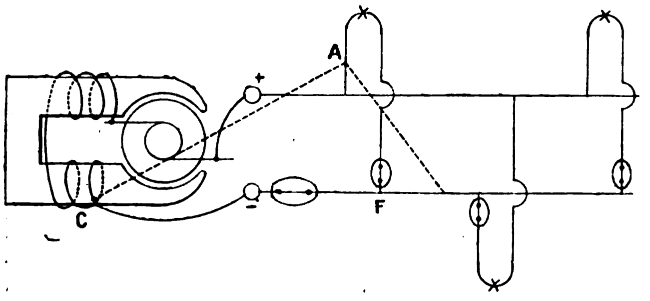

Diagram 1.

fault we supposed might happen, as in diagram 1. But in making the connections to earth we are careful to do so with that wire which has not got the fuses inserted in it, which is contrary to the action of the fault in Diagram 1. Now, if any of the negative wires come in contact with the gas and water pipes, a fuse must instantly blow as if their two conductors themselves had touched. All the electric light fittings would in this case be connected with the positive wire, the negative wire passing down the centre of the tubes. There being in the fittings only a single wire, which can be heavily insulated and made stouter, there is an additional safety against short circuits and fuse melting, besides the very great advantage of being able in a very simple way to wire each part of an electrolier or fitting. Diagram 3 illustrates how this is effected. The current travels from the contact, A, down the wire B, through the contact, C, to the switches, S, S, by the wire D, to the lamps, L, and back by the brass of the fitting to the ball and socket at the top, and away by the earth wire. The wire inside the tubes is never smaller than No. 14 S.W.G., and the contacts are made with a strong small

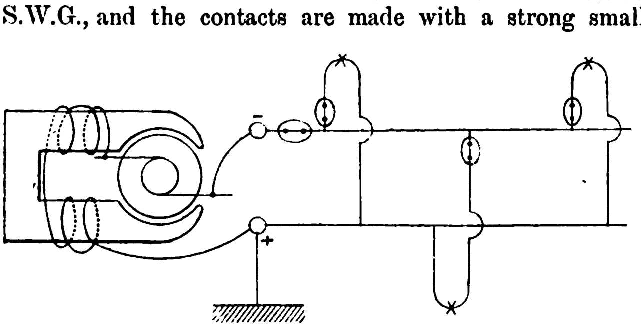

Diagram 2.

spiral spring. The contact at the ball and socket joint projects through, and, being a box spring, it gives and takes with the swing of the fitting, and scrapes on a fixed brass plate in the roof plate. Single or universal joints are quite simple to construct with this system within the same dimensions as for gas; whereas with the two wires passing through the fitting such is impossible. This method of connecting one of the wires to earth is best called the earth system. It is, however, often called the single-wire system, because in its applications to ships the hull of the ship is used as the return wire. In buildings, however, two conductors are required, and, as it is important always to be able to distinguish between the negative wire, in which the fuses are inserted, and the positive wire, which is connected to earth and all the electrical fittings, the positive wire is coloured red, and the negative wire black. The object for connecting the positive wire to earth is that red-coloured wires are usually inferior in insulation quality to black wires, and it is not so important that the return or earth wire should be so highly insulated as the leading wire. We now come to the consideration of means for minimising those most dangerous faults, opening and partial short circuits. Except the means proposed by the writer in the following paragraph, no attempt has been made to treat these faults, except by good workmanship and material. The proposal

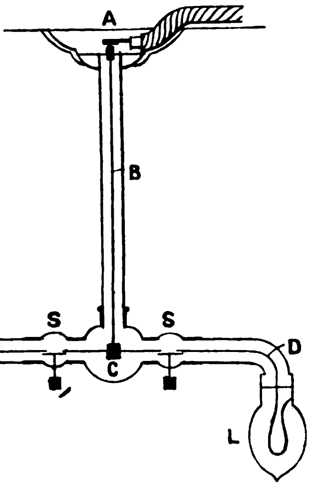

Diagram 3.

the writer makes is to universally adopt the sheathed or armoured wire system devised by him some years ago for use in the exposed and damp places on board ships using the earth wire system, and now extensively used for that purpose. The virtue of this system is that all

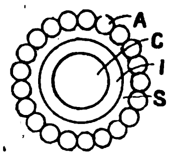

Diagram 4.

faults, partial short circuits and opening circuits, are reduced to dead short circuits. Diagram 4 is an enlarged section of an armoured wire such as is now in use. The pink portion C is the copper conductor; I is vulcanised indiarubber insulation of the highest class, with

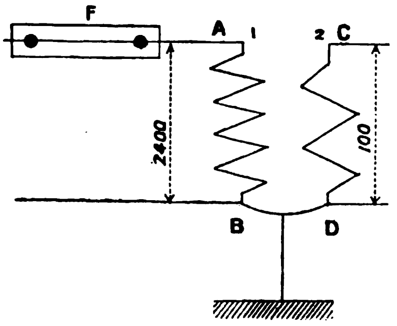

Diagram 5.

a serving of jute and special compound between it and the iron armouring, A, which is a great many times larger in cross-section than the copper conductor, care being taken that it is always more than seven times larger, this being about the difference in electric conductivity of the two metals. It will be understood that the copper wire is the lead, and the iron wire the return. It was assumed in devising this system that an opening circuit in the outer conductor was very unlikely to take place, and so it has been found in practice. It is, however, possible that the inner conductor, through undue strain or a flaw, might have an opening circuit in it, and if such were to take place, the immediate result would be that the heat generated would destroy the insulation between the two conductors, and at once effect their fusion together and a short circuit. As a matter of

fact, however, short circuits in this system have in practice been many fewer, and there have been no opening circuits or partial short circuits. How many of the short circuits were due to such faults is difficult to say—the causes of some were doubtful.

The writer is not aware of any new danger or contingency being introduced with this system of concentric wiring, although he has heard that some people object to it, and, in fact, any system in which an earth connection is introduced; but he has still to learn upon what grounds the objection is based.

In addition to the advantages above referred to, there is another of not the least importance. The electricity being entirely enclosed within the outer conductor, and the electric pressure being only from the centre point to the outer conductor, it is impossible to get a shock through anything more than a very small portion of one's flesh, such as the finger end, except by wilful contrivance.

It is advisable, before closing this subject, to consider how a system of wires supplying a town would be affected by an earth connection of one of the conductors. With any system of supply embodying the series system, I may generally say it is not advisable to employ an earth. I have expressed this point broadly, as it involves complex considerations which would take long to make quite clear. But with all systems on the parallel system, there are many points favourable to an earth connection, some of which can be gathered from foregoing descriptions. It is more important for us to find out whether there is any objection to its use, and with this in view Diagram 5 is placed before you. It illustrates a transformer with its primary leads, and an electric pressure of 2,400 volts at the terminals, A and B, where they join the primary circuit 1 of the transformer. F is a fuse in the primary circuit. 2 is the secondary circuit of the tranformer between the terminals, C and D, of which there is represented a pressure of 100 volts. The terminals, B and D, of the circuits of the transformer are connected to earth, and consequently connected together. The writer is unable to find any danger in thus connecting the 100-volt pressure circuit to the 2,400-volt pressure circuit. Nobody could get a shock to earth, because the pressure between the return wire and earth is reduced to nil. The next point is, is there any greater probability of the insulation of the transformer breaking down because the circuits are joined together at one end? This seems to the writer to be answered by a simple calculation. With the earth connection there is no pressure at one end, but all the pressure, whatever it is, at the other. With no earth connection the pressure is alike at both ends, but at each it is only half the total. The result in both cases is the same. Suppose a connection did get made between the terminals, A and C, in addition to the earth connection, why the 2,400-volt circuit would be simply short-circuited, and the fuse, F, would melt. There is, it is true, a very remote possibility of danger in the event of the great improbability of three circumstances happening in succession—viz., first of all, a connection between the terminals, A and C, as well as the earth; then, the fuse, F, not melting; and, thirdly, the circuit of the secondary of the transformer to open between the terminals, and thus put the 2,400 volts pressure on to the lamps direct, which would, as a matter of course, immediately gasp their last.

There is one other circumstance worthy of mention in favour of the earth connection. Should the wire system at any time be struck with lightning, there is at once a safe connection to earth. Instead of having to pass through a highly-insulating material as when there is no earth connections, lightning has already been known to strike overhead electric light wires, and discharge itself through the dynamos to earth, to the imminent danger of the machine.

USEFUL ELECTRICAL QUESTIONS FOR TROPICAL CLIMATES.

(*Concluded from page 256.*)

With regard to our third question, it had reference to the practical usefulness of platinum-silver coils in hot, humid climates; it being also remembered that the instruments are invariably located on the seaboard. We did not, and do not, wish to dispute the fact that platinum-silver and platinum-iridium alloys, on account of their compactness and small variability, are infinitely superior to german silver for home or continental work. If anything is wrong, it can easily be remedied, or the instrument exchanged. Spare apparatus is at hand or is readily obtainable, and no great inconvenience is likely to result if a coil should happen to develop a fault There are many things, mechanical and otherwise, however, whose constitutions but ill-adapt them for prolonged sojourn in hot countries. Our esteemed contemporary, the *Electrical Review*, says platinum-silver coils are reliable, "provided the silk covering of the wire is *well* dried at a high temperature, and the coils are *afterwards* saturated with hot, pure paraffin wax, so that moisture is excluded and not bottled up, there will be no error through polarisation." This opinion we are ready to endorse. But there is an *if*, and the question is to what extent this *if* qualifies the practical usefulness of platinum-silver coils, such, for instance, as are supplied to foreign cable stations? Perhaps Messrs. Elliott Brothers could give us the desired information?

What we want to get at is this. Certain data and certain apparatus are supplied to cable stations for the guidance and use of electricians and superintendents at those stations. Are those data and apparatus thoroughly trustworthy? We wish to obtain expressions of opinion from those practical workers abroad who have hitherto been dumb, and who, so far as we can see, are not represented in the world of letters. The platinum-silver resistances of which we have mostly had experience are: (1) 100,000ω, boxes made up of 40,000, 30,000, 20,000, and 10,000ω coils respectively; (2) slide resistances; (3) Wheatstone bridges and resistances of the dial pattern. They were all of Elliotts' manufacture. If we describe what happened at one cable station, and add that it was by no means an isolated case, our readers will see that there is some method in our madness.

The station was provided with the following testing apparatus:

Four 10-micro condensers.
One ⅓ " "
One 100,000ω resistance-box.
One shunt-box.
One dial-bridge and resistance.
One astatic galvanometer.
Batteries, etc.

The H. R. dials and shunt-box were of platinum-silver, and had been in use for about three years. Distance from sea about 50 yards. Average temperature from sunrise to sunset 28deg. C.

On inspecting the register of tests, curious discrepancies both in the C. R. and insulation resistance were noticed, and the apparatus was overhauled to discover the reason. The 1,000ω coils of the dial resistance were first tested—ratio 1,000-1,000—and came out as follows:

1. Usual way :

1,000ω = 1,001·3	6,000ω = 6,009
2,000ω = 2,001·1	7,000ω = 7,009
3,000ω = 3,000·3	8,000ω = 8,009
4,000ω = 4,002·4	9,000ω = 9,010
5,000ω = 5,002	10,000ω = 10,011

L King plug in—

9 and E = 1000	5 to 4 = 1000·3
9 to 8 = 1000	4 " 3 = 1000·6
8 " 7 = 1000·4	3 " 2 = 999·8
7 " 6 = 1001	2 " 1 = 1000
6 " 5 = 1000·7	1 to zero = 1001·2

Bridge Reversed.

Coil 1 (usual way):

1,000ω = 1,002·4	6,000ω = 6,017
2,000ω = 2,003·5	7,000ω = 7,019
3,000ω = 3,004·3	8,000ω = 8,020
4,000ω = 4,006·8	9,000ω = 9,023
5,000ω = 5,009	10,000ω = 10,023

The 1,000-1,000 ratio tested all right so long as the 10,000-10,000 was not used for some time previously. The 10,000-10,000 ratio was all wrong, and it was found that the coil on the cable side acted as a secondary cell, in-

fluencing the 1,000 coil nearest to it inductively. Charged for 30 seconds with 18 volts, it gave a discharge of 0·014 volt. Tested as a condenser, its capacity was 0·0627 micro.

The following details may be of interest:

Plugged out all other coils of balance and charged faulty coil for one minute with 18 volts. Then disconnected battery and observed with 10,000ω shunt on galvanometer. Immediate discharge 230 divisions:

1	min	185	fall	45		6	min	115	fall	7
2	„	160	„	25		7	„	106	„	9
3	„	144	„	16		8	„	99	„	7
4	„	132	„	12		9	„	93	„	6
5	„	122	„	10		10	„	87	„	6

On examination the spool was found to be badly fractured at the base, and one end of the coil—although making contact with the standard—without solder. The 1,000 coils of the dial had in every case projecting ends (bare wire) ½in. to ¾in. beyond the soldering.

The H. R. behaved in a still more extraordinary manner. Tested by bridge, 1,000-10,000.

(1) It gave
95,877·3ω corrected to 28·8c

(2) By Sir Wm. Thomson's (capacity) method,
97,350ω

(3) By deflection method,
D through 10,044·8ω (corrected) shunt 5ω = 356
d „ H R „ 50ω = 387
= 91,789ω

and it required 8,000ω (roughly) more in circuit to reduce *d* to D.

(4) By deflection,
91,347ω

(5) By deflection,
90,972ω.

The box was then left until the next day, when it showed a residual charge of 10 divisions on an unshunted galvanometer. The 20,000 coil was then charged for one minute with 18 volts and observed.

Immediate discharge = 6 divisions.
After 1 minute = 2 „

Charged 30,000ω coil as above.

Immediate discharge	= 350 divisions.		
After 30 seconds	= 190 „	fall	160
„ 1 minute	= 155 „	„	35
„ 1·30 seconds	= 140 „	„	15

Charged 40,000ω coil.

Immediate discharge off scale,			
After 30 seconds	= 300 divisions.		
„ 1 minute	= 270 „	fall	30
„ 1.30 seconds	= 255 „	„	15
„ 2 minutes	= 230 „	„	25
„ 2.30 seconds	= 215 „	„	15
„ 3 minutes	= 208 „	„	7

The 10,000ω coil showed no residual charge, but was low in value.

The box was then earthed for ten minutes, and the inductive effect of each coil upon the other coils tried, but no such effect was observable. But even after the ten minutes' earth, the coils gave deflections representing a remaining charge of:

30,000 coil = 40 divisions
40,000 „ = 70 „
20,000 „ = 2 „

These eccentricities on the part of the H.R. made, as may be readily imagined, a considerable and variable difference in the calculated absolute insulation resistance of the cable, variable because D varied with the condition (a condition depending largely upon the humidity of the atmosphere) of the H.R. at the time of observation. In practice the discrepancy amounted to 25 per cent.

After making experiments with coils in which the retentive effects given by the coils of the H.R. were reproduced, it became evident that the phenomenon was due to dampness. The coils were therefore carefully examined and found to be quite free from paraffin wax in several places. They were then subjected to a heat sufficient to evaporate moisture without injuring the insulation or the soldering, and reparaffined at a high temperature. Under this treatment the retentive effect finally disappeared.

Now, german silver, although it has a higher coefficient, is not open to this objection, and it is a question whether for tropical climates it is not better to make the coils of this alloy. Platinum-silver coils require not only to be very carefully made, but to be carefully treated. We have seen the cases containing testing apparatus lying for many hours in the blazing sunlight. The resistance-boxes are in some places placed periodically in the sun *to dry* before commencing to test, and so on. The fault is not necessarily, though probably, with the maker. All these things have to be considered, however, and therefore we have asked our readers in the tropics to tell us what they think of the questions we have proposed.

THE TRANSMISSION OF POWER BY ELECTRICITY.*

BY FRANK J. SPRAGUE.

The transmission of power by electricity is now an established fact, and every day, for the ordinary uses of life, its application is rapidly spreading. The principles of its application are well settled. The dynamo and motor have been brought to a remarkably high efficiency and leave little to be desired as converters of energy. The future of the transmission of power from central stations, under ordinary conditions, is a matter of commercial development. The special application of the transmission of energy over long distances depends chiefly upon the demand which exists for such transmission and the intelligent application of principles already well known. Distance is a relative term. It does not seem a difficult matter to transmit 5 h.p. ten miles, but a gigantic problem to transmit 1,000 h.p. one mile; the latter appeals to our imagination, and yet the former is, in one sense, the more difficult problem, not so much because of any difference in the general principles involved, as in the fact that in the construction of machines of high E.M.F. we meet with more serious difficulties in the matter of insulation and the element of personal danger to the operator.

It is not my intention to enter into any general discussion of the question, nor to go into the particulars of dynamo and motor construction, for the limits of this paper would not permit this; but I shall briefly point out the different phases which the transmission of power by electricity may assume, show some of the general conditions which must be met, emphasise the practicability of such transmission, and then more particularly discuss a new method for the determination of the elements of a single transmission which my own practice has brought out, and which I have found it advisable to adopt. I shall here consider only the use of a continuous current and a direct transmission.

For the purpose of this paper, we may consider the following cases of transmission:

1. Transmission from a central station conveniently situated near the centre of a manufacturing district, over an area of from 1 to 100 square miles, in units varying from a fraction of a horse-power to 50 or 100 h.p. Such a system is illustrated by the Edison two and three wire circuits in operation in a large number of cities in the United States. Referring to my own work alone, its practicability is illustrated by the fact that in Boston I have nearly 150 motors in operation, in New York about 125, and in New Orleans nearly 100; there being in various stations not less than 1,200 machines, varying from ½ h.p. to 30 h.p., and used in no less than 130 different industries. These machines are operated under potentials varying from 100 to 440 volts, and are run on constant potential circuits. The maximum distance in this class of work is, at present, about one mile on 220-volts circuit, and the practical limit for this potential from a single station is about four square miles.

In considering how far this central station work can be carried, we must bear in mind certain facts; power transmitted means the transference of an energy whose value may be expressed, as in all cases of fluid transmission, by the product of the quantity and pressure—that is, by the product of the E.M.F. and the current. With any given amount of energy transmitted, the E.M.F. and the current will vary inversely. The laws of distribution are clear. With any given work done, loss on the line, E.M.F. at the terminals of the motor, and distribution, the weight of the copper will vary as the square of the distance, its cross-section, of course, varying directly as the distance.

* A lecture delivered before the Franklin Institute, November 12, 1888.

Digitized by Google

With the same conditions, the weight will vary inversely as the square of the E.M.F. used at the motor. With the same cross-section of conductor, the distance over which a given amount of power can be transmitted will vary as the square of the E.M.F. If the weight of copper is fixed with any given amount of power transmitted and given loss in distribution, the distance over which the power can be transmitted will vary directly as the E.M.F. Hence, if it is practical to economically transmit power one mile under 200-volts pressure—that is, if the investment in copper is not disproportionate—then, by increasing our pressure to 800 volts, we can transmit this power four miles without changing the ratio of the investment. Of course, I am now speaking of the use of a bare wire and assuming that the cost of stringing the four miles of given weight of wire is no more than stringing an equal weight one mile. Of course, this is not strictly so. As a matter of fact, however, it is a practical thing to transmit and deliver over an area of 100 square miles, from one central station, under a pressure not exceeding 1,000 volts; and the larger the amount of power distributed and the greater the number of units, the more cheaply it can be done. The question arises, "Would it be economical, in a district of this character, to deal with the larger horse-powers?" My answer is unquestionably, "yes." It is true that the actual efficiency of double conversion would vary from 50 to 70 per cent., depending upon the distance and the pressure used, but experience has developed the fact that not over about 35 to 40 per cent. of the maximum capacity of all the machines in a circuit represents the average duty demanded; and since this is so, it follows that the amount of power that can be contracted for will at least equal, probably considerably exceed, the steam-power in the central station. I say "steam power" because in a large majority of cases in this kind of transmission steam, and not water, will be the prime source of energy. When we consider the economy of operating a large, well-designed, and properly constructed steam plant, and the great advantage to the user where the electric motor replaces the ordinary steam engine, it does not need a very shrewd commercial sense to see the advantages of this method. In fact, there is not a city in the United States, no matter how numerous its factories, which could not have them run better than to-day by a well-constructed electrical plant, working under pressures which would not be dangerous to life.

2. Somewhat analagous to the system we have just discussed is the transmission at constant potential, with the motors applied with various loads at constantly varying points. Such a system of transmission is that which exists in the parallel circuit system for railroad work. There are now in the United States alone no less than 60 or 70 electric railways in operation or under construction. The most extensive of these, up to the present writing, is the Richmond Union Passenger Railway, whose characteristics may be cited as an illustration. This has about 12 miles of track, and is operated under a pressure of about 450 volts. The central station has a capacity of about 375 h.p. The farthest point reached is about three and one-half miles from the station. The equipment consists of 41 cars, with 82 machines whose aggregate normal capacity is between 600 and 700 h.p., nearly double the steam capacity. The car units develop anywhere from nothing to 20 h.p. The maximum load which has been put upon the system at one point at any time is the starting of about 22 cars about two miles from the station, requiring, probably, about 125 to 150 h.p. This road now having made nearly 600,000 miles, the practicability of this kind of transmission may be accepted as an assured fact.

3. The transmission from one station to another, at which latter point are a number of independent machines, each of which has a variable load, and is required to run at constant speed. An example of this is the transmission from a water-power to a stamp-mill, where the different batteries of stamps are operated by independent machines. The most satisfactory method is to maintain at the receiving station a constant potential, and to use for the receiving machines motors wound to be self-regulating, according to laws which I gave some time since. The dynamos should either be compound wound, or the field regulators adapted to increase the E.M.F. of the machine as the load increases. Constancy of prime speed is an essential, or if it does not exist then there must be a combined mechanical and electrical governor which will assure a definite E.M.F., which shall correspond to each variation of the current.

4. The transmission between two stations as last mentioned, save that the condition of automatic regulation is not essential. In this case the dynamos may be either shunt, compound, or series wound, and the motors either shunt, cumulative, or series. Such a plant is now running in one of the mines at Aspen, Col. The E.M.F. there used is about 450 volts and the distance somewhere about a mile.

5. Transmission with a single line over a long distance, with the motors distributed throughout the entire line. This is a case which may occur in some manufacturing districts, but is more apt to occur in such work as canal building, dredging, or mining in river beds. It can be accomplished by the use of a constant current circuit, using constant current motors, or with the same aggregate E.M.F. on a constant potential circuit. A marked case is the mining operations carried on at the Big Bend Tunnel of California, in a large river canyon, where about a dozen machines, developing from 5 to 10 h.p., are used for operating pumps and derricks, and are supplied by two lines of from 600 to 1,000 volts potential over a distance of about eight miles from the central station.

Thus far I have considered the distribution with a practically constant potential at the motors, and the parallel method of distribution, as distinguished from the constant current method, where the motors are in series. This last, for large powers and many machines, is a limited and unnatural method, the former a comprehensive and natural method, which facts are entirely independent of the question of relative electrical potentials or currents, because, on constant potential circuits, we can work at 100, 1,000, or 5,000 volts if we choose.

Among some of the special cases of power transmission I will briefly note the following:

6. The transmission from one point to another, using two series-wound machines, where the motor has a constant torque or a load per turn. The motor being at rest, as the E.M.F. of the generator is raised by increasing its speed, or by increasing the resistance of a shunt around its field with any given speed, the current, which may be expressed by

$$\frac{E}{K}$$

will increase until the torque is great enough to start the motor against its load, when the current will become stationary. A motor E.M.F. being now created, the current is expressed by

$$\frac{E' - e}{K} = \frac{E}{K},$$

Any increase of the E.M.F. of the generator will be followed by an equal increment in the motor E.M.F., the difference between the two, and hence the current, remaining perfectly constant. The speed of the motor being known for one E.M.F. and load, its speed for any other E.M.F. may be determined, and fast or slow hoisting be regulated entirely at the generating station.

7. The transmission to one point from another with a single generator and a single motor with variable loads presents two solutions. The first is the use of the compound dynamo and differential motor; but a far more interesting solution is the use of two series machines, which, when properly proportioned, become perfectly self-regulating. I will briefly touch upon the theory of this method of transmission. We have the condition that the same current passes through each field and armature, and also the condition that the speed is constant, while the work is variable. Since work may be expressed as a product of speed and torque, and since the speed is constant, it follows that the motor torque must vary directly as the work. Again, we have as an expression for the work done the product e C. Since the speed of the motor is constant, e must vary directly as the strength of the field, which, where the magnetisation is low, will vary directly as the current, and when more highly magnetised in a much less degree. E being E.M.F. of the generator and K the resistance of the circuit, we have—

$$C = \frac{E - e}{K},$$

and, as we have already stated,

E varies as e, as $E - e$, as C,

and work,

varies as e C, as C^2, as e^2, as E^2.

The dynamo, likewise, being driven at a constant speed, E likewise varies as the strength of its field. If m equals the number of turns of wire in the dynamo field, and n those in the motor field, then the ampere-turns or magnetising forces are expressed by m C and n C. It follows from what proceeds that the magnetisations due to m C and n C should vary in the same proportion; in other words, the characteristics of the generator and the motor must be similar between the limits of the variation in load. Should the machines used be improperly proportioned, then the regulation can be largely determined by putting a resistance in the line circuit, or shunting one or other of the fields with a resistance. The electrical efficiency of the circuit being

$$\frac{e}{E},$$

we have the following fact: That the electrical efficiency is a constant for all loads with the limit of automatic regulation. If the machines are of the same general type, then, when correctly proportioned, the ratio of their weights and watt capacities should be the same as the electrical efficiencies of the circuit.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

COMPANIES AND COMPETITION.

Once upon a time, *vide* the tales of the Arabian Nights, we heard a well-known gentleman speaking of a reform, or series of reforms, he heartily desired, say that no opportunity should be allowed to pass without urging the necessity for such reforms. It is merely a statement of fact to say that individuals cannot undertake central station work—that is, the general distribution of light and power to a whole town, or a whole district of a very large town. An individual or a private firm may initiate such distribution, but the limits of their work are soon reached. The wisest plan to obtain the necessary capital, and the necessary interest in the work, is to promote a local company, in which the shares are held by local people, the consumers of the light and power. With certain reservations, we are altogether against the introduction of what may be called foreign capital. By this we do not mean the introduction of French, German, or American capital, but rather that London speculators and capitalists should not find money for local companies in country towns. There is a move in the right direction when we find Taunton, Bath, Bournemouth, Brighton, etc., favouring purely local companies. The electrical industry, so far as the distribution of light and power are concerned, has much to learn from the history of gas companies. These have been eminently successful companies, and not altogether because of being monopolies. It is almost silly to suggest the possibility of the successful existence of two small gas companies in a small town. Some people who cry out for unrestricted competition, ask for it for different reasons. The buyer of the product wants to buy at the cheapest rate, and he thinks competition just and right. The great capitalist, looking far ahead, sees a way of making competition pay. Shareholders have to bear the loss, and to make this as small as possible sell out at the best price they can get. A long period of no dividends, and with future prospects with competition somewhat gloomy, means a succession of shareholders selling out at a lower and a lower price—each losing a little, and not liking his loss. The wily capitalist buys largely at the low rate, gets a controlling interest, amalgamates the competing companies, and pockets thousands. Our friends in America are great adepts at this kind of thing, and we venture to think the lessons they have taught are not falling upon barren ground in England. At the end of the game the public laugh because they have been gainers, the prime movers in the scheme laugh because their pockets are filled to repletion. The only sufferers are the early shareholders, about whom no one cares, as they are expected to look after themselves; but, looking at the whole business from an economic point of view, a lot of good money has been thrown

Digitized by Google

away. A large part of this may be saved if the system of local companies is followed. There should then be no great waste. The local people can judge better than outsiders as to their real wants, and can see whether under the conditions promised these are likely to be supplied. Then, again, they are gainers from the best possible point of view, in that they are producers of their own goods. Deducting the percentage necessary for carrying on the business, we contend that they get their wants supplied at about cost price, and more than this can no man desire. Let us explain more fully, and take, say Bath, as a concrete example. The local company to be formed at Bath asks for a capital of £25,000. Suppose the residents who want light and power subscribe this capital. They obtain the light and power at an agreed-upon price, and subsequently, if the price is properly arranged, get a dividend. This dividend, we take it, really acts as if the price of the light was obtained at a lower rate. A local company, whose shareholders are users of the goods manufactured, is really a co-operative concern under another name, and there is no known method of production more economical than this. We, of course, assume that the business is conducted in the ordinary fashion by reputable men. In every case, therefore, when a bona fide local company is promoted it has our heartiest sympathies for its success. When we come to deal with London the case is different. No local company can be formed to supply such a huge place, and, according to all the signs of the times, competition will take place till the weakest goes to the wall in each area. Once more we say the shareholders are to be pitied. As will be seen from our other columns, the enquiry referred to in our last issue has commenced, and the first text dealt with is this very one of competition. The wealthiest company, according to the first day's evidence, favours it, but no doubt further evidence will be given on the other side. Even at this early date we hear of rival companies canvassing the same people—one company fixing a time for supply and losing the order, another taking the order, wiring the place, and not fixing a time for supply, rather leaving it to be inferred that the supply can be obtained at once. Other companies are prospecting the same district, and no doubt will canvass the same people. Be it remembered, too, that competition cannot be restricted to two companies, but must be free to all. And so we may see half-a-dozen contiguous houses supplied by half-a-dozen different companies. Each company, of course, will claim the same facilities for laying mains, and, if carried to extremes, the result of unrestricted competition will be disastrous. We earnestly ask those who are so eager to get to work to pause before their action leads to almost irretrievable confusion, and by such forethought adding to the great possibility of future success.

CORRESPONDENCE.

ELECTRIC LIGHTING IN LONDON.

To the Editor of The Electrical Engineer.

Sir,—From a letter which recently appeared in your columns, it appears that the Board of Trade has under consideration a number of applications for provisional orders under the provisions of the Electric Lighting Acts in respect of areas within the metropolis.

Now, in considering these applications the Board of Trade will no doubt have due regard to the interests of the public, and in so doing will especially keep two ends in view—namely:

1. To minimise the serious inconvenience which must arise from the laying of mains and the consequent disturbance of the roadway during that process, especially if concurrent powers are granted within the same area to rival companies.

2. To obtain for the public the lowest possible price compatible with efficiency in respect of the electricity to be supplied.

Hitherto it seems to have been assumed that it is necessary that the company which contracts for the supply of electricity should also own and lay down the mains along which the electricity, when generated, is conducted to the consumer. It is, however, a matter for serious consideration whether it is necessary to assume this.

Is there any reason why the local authority which controls any given area should not itself own and lay down the mains necessary for conducting electricity to a point within the reach of the private consumer? Assuming that such a step were taken by the local authority, it would be easy for such authority to invite tenders from the various electric supply companies for the supply of the required amount of electricity along the mains owned by the local authority, and to charge the company whose tender is accepted a rent sufficient to cover interest on capital expended in laying down and depreciation of the mains.

The advantages of such a plan are obvious. The roadway would have to be disturbed once, and once only. The local authority would control the electric lighting within its own area, and be in a position at any time to take advantage of the most efficient and cheapest system of electric lighting.

A similar problem has already presented itself for solution in the case of gas, water, and tramway companies.

In the two former cases the local authorities failed to move in the matter at the outset, and the result has been high prices during the existence of the monopoly, and the payment of heavy sums under the head of goodwill when the local authorities have at length taken into their own hands the various undertakings.

In the case of some tramways, however, the local authority (*e.g.*, in Manchester and Liverpool) has taken the initiative, and itself laid down and owned the tram-lines, and the results have fully justified them in this course.

It must not be forgotten that a system of electric lighting which is to-day cheap and efficient, may, after a lapse of twelve months, be dear and obsolete.

You will, I am sure, be doing a public service by opening your columns to a discussion which may tend to a solution of a difficult problem of grave importance.—Yours, etc.,

April 2, 1889. H. S. H.

THE LATE C. H. B. PATEY, C.B.

It was with very great regret that the many friends of Mr. Patey heard of his death last week. The sad occurrence took place rather unexpectedly on the Thursday afternoon at his residence, South Lawn, Bickley, and the funeral took place on Tuesday last in the presence of a large number of friends. Charles Henry Bennet Patey was a son of the late Admiral C. G. E. Patey, C.M.G. He entered the Post Office at the age of 19, as a clerk in the secretary's office, in the year 1863. Shortly afterwards, Parliament sanctioned the working of telegraphs by the State, and throughout the arduous work which fell upon the Post Office

Digitized by Google

for some years, in effecting the necessary purchases from telegraph and railway companies and in organising the new service, Mr. Patey rendered valuable assistance, and attracted the notice of his official superiors by the energy and ability with which he discharged his duties. In 1877 he was appointed Assistant-Secretary to the Post Office, and in 1882 the late Mr. Fawcett promoted him to the post of Third Secretary. Thus during the last 12 years Mr. Patey has taken an active part in the management of the Post Office, the general superintendence of the telegraphic service being specially in his charge. When, in 1881, the newly-introduced telephone was judicially declared to be a telegraph, it became Mr. Patey's duty to conduct the delicate negotiations with the telephone companies, which resulted in defining their relations with the department. A little later, sixpenny telegrams were authorised; and to Mr. Patey it fell to place the service on a footing to enable it to cope with the vast increase in the number of messages to be transmitted. Up to the very moment of his last illness he was busily engaged in the pending negotiations and arrangements in relation to the purchase and working of the Submarine Companies' cables. He represented the country from time to time at meetings of the International Telegraph Congress, and on the conference relating to the protection of submarine cables, and conducted frequent negotiations with the Continental Governments on the subject of international telegraphy. There can be no doubt that the strain of work, which was always increasing, and in which he took an intense interest, told on Mr. Patey's strength. About five years ago he suffered from a very severe attack of inflammation of the lungs, and, although his recovery appeared to be complete, his constitution had probably been enfeebled. Mr. Patey was at work at the Post Office up to the end of the week before last; but on the Sunday he was pronounced to be suffering from a return of his old complaint. His condition was not, however, considered to be in any way critical until very shortly before his death, when the action of the heart was found to be failing. He was in his forty-fifth year, and leaves a widow and five sons. Mr. Patey was a vigorous and able administrator, and his loss will be felt in the department which he so zealously served, while those with whom he worked will long miss and lament the genial and manly comrade struck down in the prime of life. Mr. Patey received the distinction of the Companionship of the Bath in the year 1886, on account of his services to the State. Not only can the highest praise be meted out to the late Mr. Patey in his official capacity, but his many personal friends will acknowledge that whatever words of praise may be given can never adequately represent the true state of the case.

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

(Concluded from page 262).

A much simpler pattern of lamp has been several times described with various modifications in detail by Jaspar, 1878; Romanze (3901[81]), Andrews (3393[82]), and lastly by Menges, 1887, whose form is shown in Fig. 22. Here the long core, S N, is drawn up into the solenoid, wound differentially with a coarse wire, A, and a fine wire winding, B. A heavy piston of metal on the top of the upper carbon-holder, *d*, serves both to counterpoise the weight of the core, and to check, as it slides in the surrounding tubes, any too sudden movements. It is often claimed for solenoid lamps that the absence from them of all mechanism renders them superior to all other species of lamps. Yet they are not free from defects; they do not always burn steadily; some of them have the evil habit of "pumping"; and so simple a matter as the elongation of the cord which connects the plungers may put their regulating properties to confusion. In a recent modification by Doubrava the iron cores are fixed, and the solenoid coils slide up and down over them, giving motion to the carbons.

The *screw-feed* lamps have been already touched on. Of these, the most successful in practice is the Cance lamp (3976[81]), which operates by the weight of the upper carbon. The screw is prevented from turning by a nut gripped until feeding is necessary. In Siemens' holophote lamp (6987[87]), and in Maquaire's new lamp (1889), the mechanical turning of the screw forces the carbons forward.

Amongst *magnetic clutch*-lamps the Gulcher lamp, as improved by the Gulcher Company (Whiteman, 1915[82]), still holds its own. In this lamp the single counterpoised horseshoe electromagnet—with unequal limbs—sticks itself on by one pole to the iron carbon-rod, and by the other pole attracts itself upward to strike the arc. For constant potential work it is a very steady lamp. More recently, magnetic clutch-wheels have been used by Dittmar (1886), and by Trott and Fenton (6910[84]).

Motor-lamps have been devised from time to time, those of Tchikoleff, Schuckert, and Gray being perhaps the best until recently. The latest lamp of this type is that of Maquaire (1889). In this lamp there is a Pacinotti ring upon a vertical pivot, on which a worm is cut. This gears into a large wheel, the pinion of which drives the upper carbon-holder by a rack. The motor ring stands between the pole-pieces of

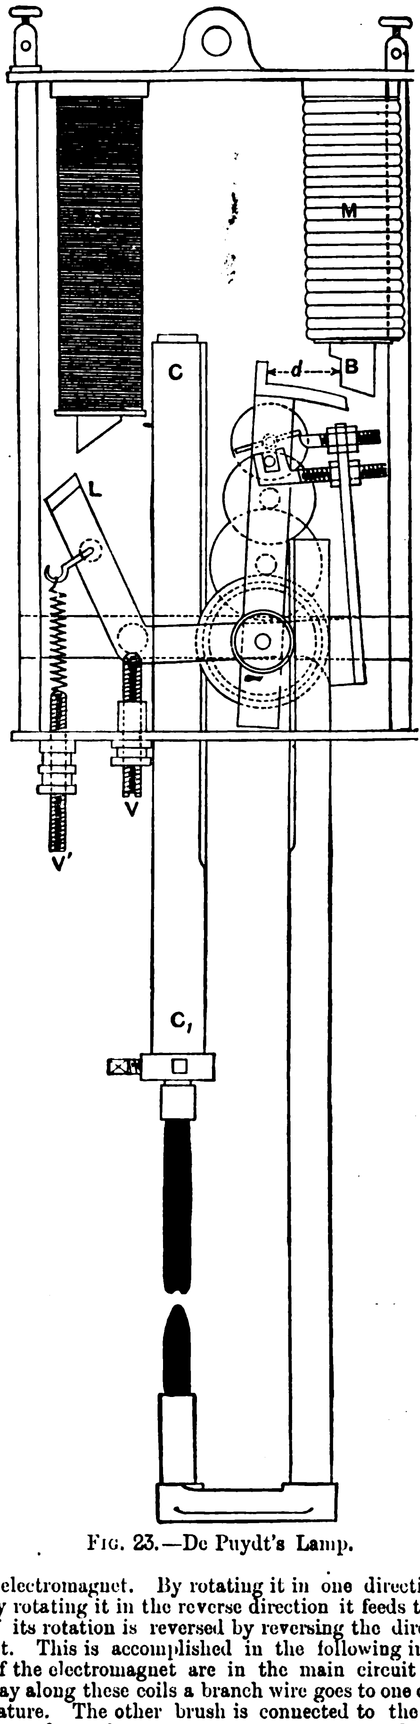

FIG. 23.—De Puydt's Lamp.

a powerful electromagnet. By rotating it in one direction it strikes the arc; by rotating it in the reverse direction it feeds the arc. The direction of its rotation is reversed by reversing the direction of the current in it. This is accomplished in the following ingenious way. The coils of the electromagnet are in the main circuit; and from a point midway along these coils a branch wire goes to one of the brushes of the armature. The other brush is connected to the tongue of a sort of relay, and stands between two contacts, one of which goes to one end, the other to the other end of the coils on the electromagnet. By raising or lowering the tongue the armature is thus connected as a shunt, either to one-half of the magnet-coils or to the other, the current in it being in opposite directions in the two cases. The tongue of the relay is controlled by a separate shunt-coil, which attracts the

* Paper read before the Society of Arts, March 6th.

tongue in order to feed the arc. The feed action of this lamp is extremely delicate.

It would be impossible, in the scope of this paper, to dwell on the *hydrostatic feeds*, on the various modes of producing *vibrating feeds*

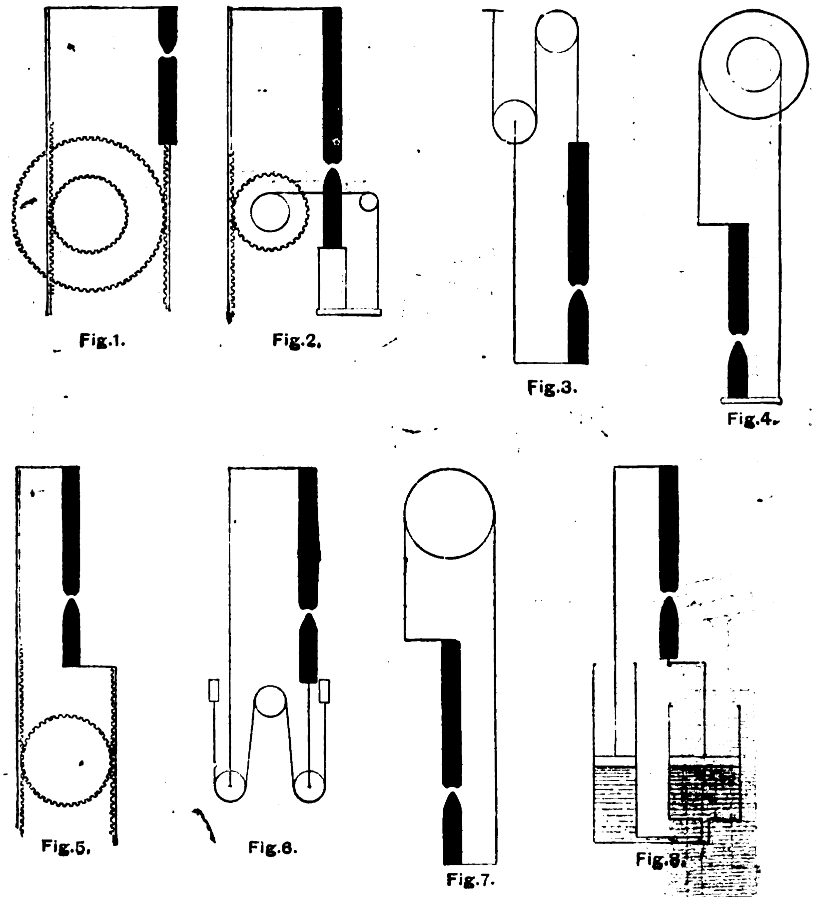

FIG. 24.—Modes of Focussing.

and *hammering feeds*, which have been from time to time suggested. The notion of having a *continuous* feed, the rate of which should be varied as required, is an enticing one, but it has never been made a

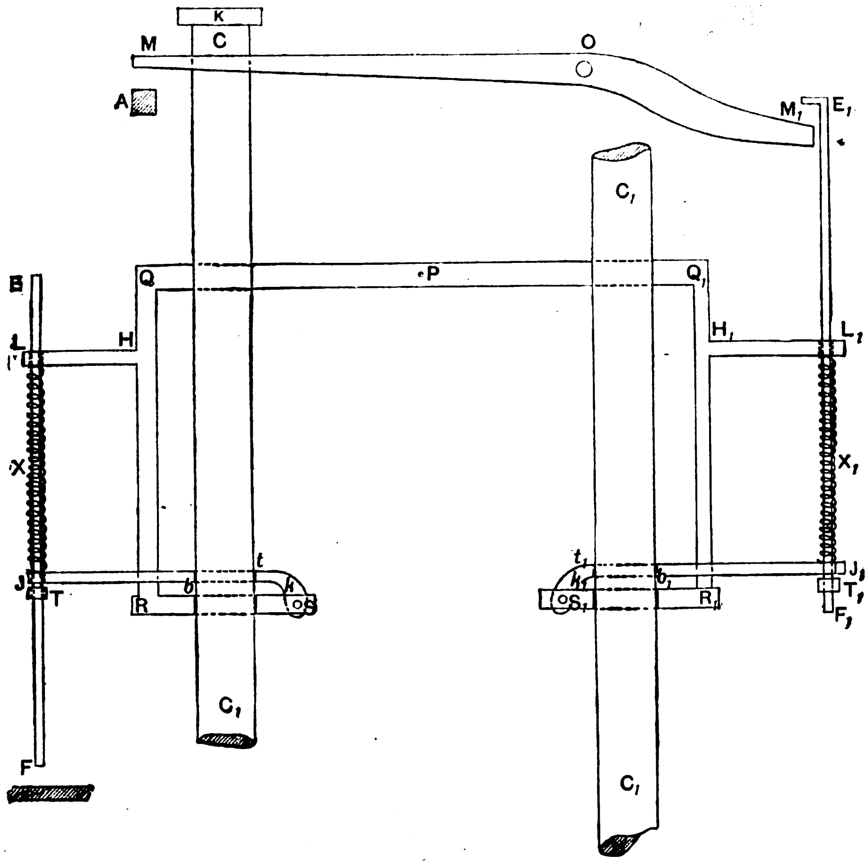

FIG. 26.—Mechanism of Thomson-Rice Lamp.

practical success. Neither have the periodic methods of feeding, at which Mr. Brockie made so brave an attempt in 1881; the flavour of which indiscretion still clings about him in spite of the admirable lamps which he has produced in later years. Mr. Brockie's various forms of arc lamp would indeed well illustrate the whole range of the subject, and the same thing might be said about the numerous successive types of lamp produced by Mr. Crompton. Mr. Brockie has lately produced an excellent little projector lamp for use in the optical lantern, having the negative carbon pressed by spring against abutment screws of steel, whilst the upper carbon is fed forward by a nipping-lever controlled by a solenoid. *Abutment* lamps and *projector* lamps form separate classes by themselves, which cannot here be discussed.

Many of the points alluded to in the preceding descriptions are illustrated by the action of the De Puydt lamp, Fig. 25. This is a

Digitized by Google

rack-train lamp which strikes its arc by lowering the lower carbon and raising the upper simultaneously, and feeds with a fly and detent controlled by a shunt-magnet. The main-circuit magnet, M, attracts obliquely its armature, rocking the train of wheels around the pivot of the first wheel. A lever, L, bent to an elbow which rests on the set screw, V, is also pivoted around the same arbor, and has a vertical arm which carries two attachments; a fork which engages on a pin on the train-frame, and a detent which arrests the fly. The other end of the lever, L, is held back by a spring, but can be attracted up by the shunt-magnet, S, when the detent is to be released in order to feed,

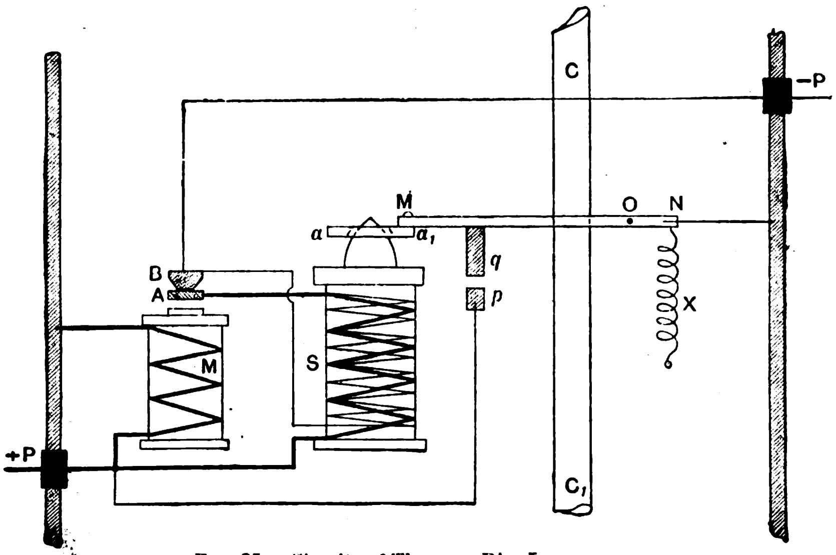

Fig. 25.—Circuits of Thomson-Rice Lamp.

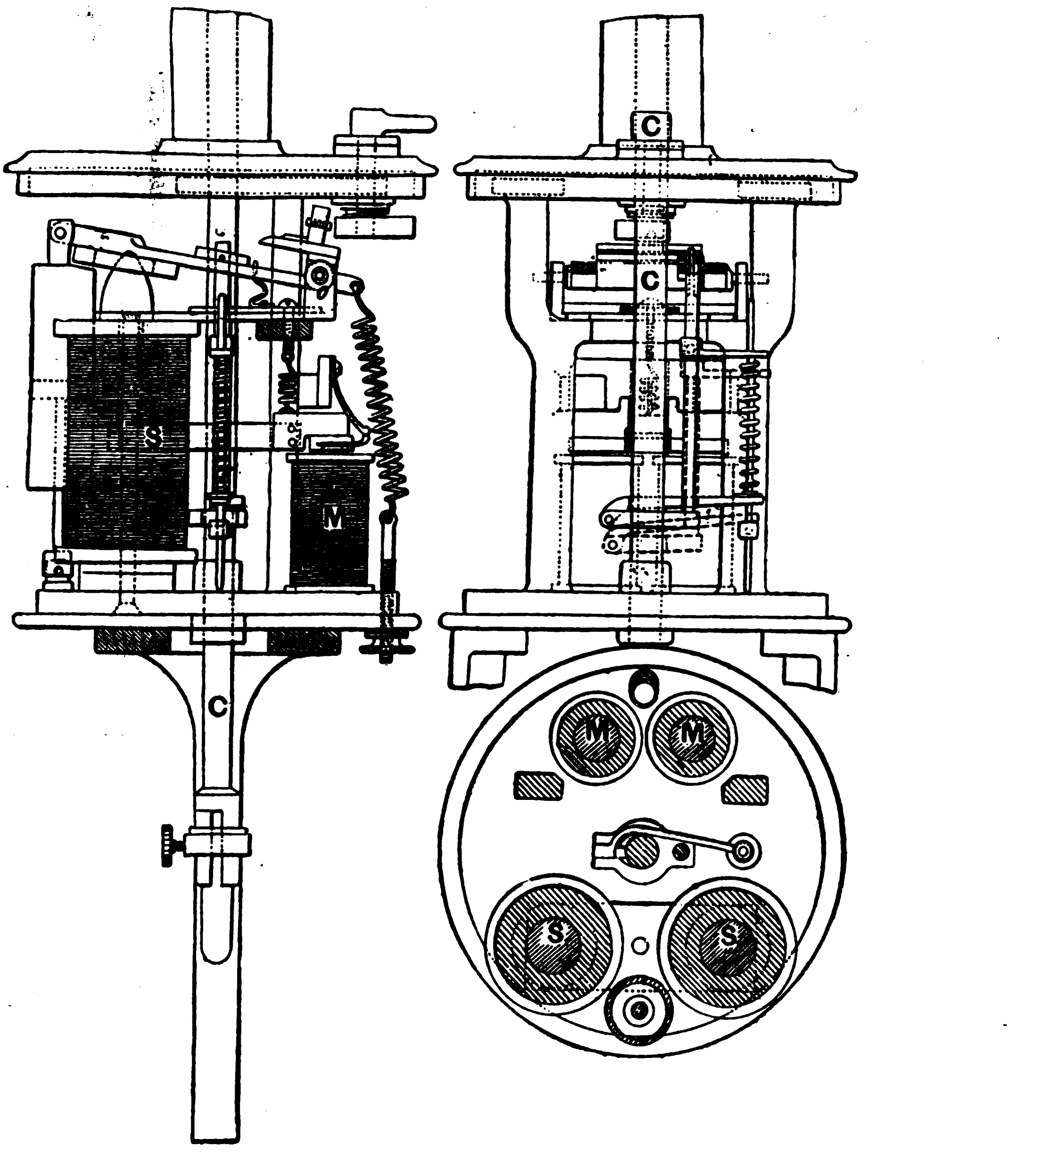

Fig. 27.—General view of Thomson-Rice Lamp. M. The cut-out (or cut-in) electromagnet which opens the contacts of the coarse-wire winding on the electromagnet, S. S. The principal electromagnet, wound with fine and coarse wire. The armature of this electromagnet is attached to a lever pivoted at O, and held at its other end by a strong spiral spring. This armature, in sinking, opens the clutch, and, in rising, closes it on the carbon-rod, which it raises.

Product-Regulation.

Before passing away from the feeding mechanisms, we may return to the question of regulation in general, and in particular to the point that the function of the mechanism of the lamp is to maintain constant one of the two factors of the electric energy, the dynamo being responsible for the other. That part of the electric mechanism which controls the feed is responsible for the steady working of the lamp; and it is this which has to be sensitive to the fall of the current (in constant potential lamps), or to the rise of the potential (in constant current lamps). It is this which must control the feeding mechanism

of the lamp. It may be remarked that the striking electromagnet represents the muscle of the lamp, but the feeding electromagnet represents the brains. Now, if the brains of the lamp have to think about, and control, one factor in the product, why can they be not made to think about and control the product itself? Such a lamp, in which the controlling part is neither an ampere-meter (main-circuit) device, nor yet a voltmeter (shunt) device, but a wattmeter device, ought to make the lamp independent of any fluctuations in the supply. Product regulation is clearly in the abstract better than regulation either by the amperes alone or by the volts alone, or by the difference between them; and the mechanism is certainly such as can be constructed. Such a lamp ought to run on any circuit. Let it be remembered that on a constant potential circuit a shunt-magnet can do no more than a spring might do. Neither can a main-circuit magnet in a constant current circuit do more than a spring. A lamp in which both coils are properly combined, ought to be capable of working on either kind of circuit. Indeed, there are some existing lamps which will very nearly do so.

Relay Lamps.

It is evident that the brains of the lamp need not necessarily be placed inside the lamp itself; the device of using a sort of *relay*, outside the lamp, to watch the lamp and control its feed, is one that has been frequently suggested (Crompton, Abdank, Gerard, &c.). There is one lamp (Jolin, 2570^{83}), in which a shunt relay, itself too weak to move the feed tilting-plate, does the work by opening and closing one of the circuits of a double, differentially wound main-circuit electromagnet.

Retarding Mechanisms.

It would be very easy to write a whole chapter on fans, air dashpots, glycerine dashpots, and the innumerable devices which have been

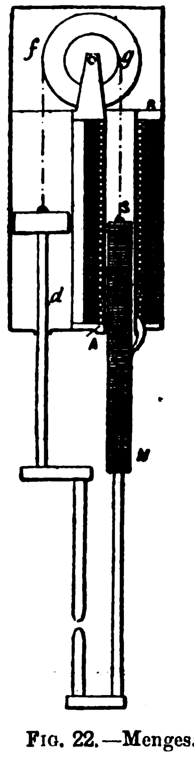

Fig. 22.—Menges.

tried. Two are worthy of mention—namely, Hopkinson's device (153^{81}) of altering the rate of feed by raising or lowering mercury in a vessel in which a fan is continuously rotating, and Brockie's suggestion of a liquid brake-wheel containing internal partitions, communicating by small apertures, so that a liquid could flow but slowly from one chamber to another.

Replacement Mechanisms.

These may be classified as follows:

(*a.*) In rack-train lamps, a ratchet-wheel on first or second member of train.

(*b.*) In clutch lamps with loose clutches, none required.

(*c.*) In forward-feeding clutch lamps, some device for loosening the clutch.

(*d.*) In screw feed lamps, some device for unclamping the screw gearing.

Focussing Mechanisms.

The various ways of giving to the carbons the desired differential rates of approach are best classified by reference to Fig. 24, which gives four methods of producing a motion of the carbons in the ratio of two to one, and four methods of "commercial focussing," in which the carbons are moved toward one another at equal rates.

Change-over Mechanisms.

These may be classified into those which are purely mechanical (Brush, Thomson-Rice, Bürgin, Crompton-Crabb, etc.), and those which are electrical, the current being switched off from one pair of carbons, and switched on to another (Weston, 1163^{82}; Waterhouse, 5185^{81}; Trott and Fenton, 6910^{87}; Noble, 16376^{87}; etc.).

Cut-out Mechanisms.

"Cut-out" mechanisms may also be purely mechanical; but they are more usually electrical, and, in modern forms, enable the lamp to "cut-in" again, on the re-establishment of its proper circuit. Cut-outs which enable a shunt-magnet to strike and feed the arc are described by Lever (8443^{84} and 11501^{84}), and are used in the Thomson-Rice lamp. The latest devices are those of Lauckert (5707^{87}), and Phillips and Harrison (7235^{87}). In many lamps the cut-out circuit is merely a shunt electromagnet stiffly set, which, on the failure of the lamp, receives the whole current, and pulls over a cut-out switch. Gerard (4792^{81}) describes several such devices, as well as a cut-out depending on expansion by heat. In the Pilsen lamp (Fig. 21), the cut-out is in an auxiliary main circuit. Cut-outs depending on the fusion of a wire or of a washer have been proposed by Lontin (2094^{77}), Basilevsky (5026^{84}), and McDill (1887).

The action of change-over and cut-out mechanisms is well illustrated by reference to the Thomson-Rice lamp, of which Fig. 25 illustrates the electrical mechanism, and Fig. 26 the mechanical mechanism of the lamp. The terminals are marked + P and − P. The carbon-rods, C C and C_1, C_1, are held up by their respective clutches, which are identical with those of the Thomson-Houston lamp (Fig. 14) already described. The clutches, when the lamp is not at work, are themselves held up by the spiral springs, X X, which push down the levers, J and J_1, and push up the arms, H L, and H_1 L_1, so gripping the rods. The principal electromagnet, S, with its conical poles, has a pierced armature, *a a*, mounted on the end of a strong lever, M N (Fig. 25), which is pivoted at O, the short tail, O N, being pulled down by a powerful spring, X. This lever, thus held up above the poles of the electromagnet, is connected to point P (Fig. 26) of the clutch-frame, and holds it up. The adjusting nuts of this frame are so set that when P descends, the lower end, F, of the pin, E F, strikes on the base plate and opens the clutch for the left carbon-rod, so striking the arc of this pair of rods. When the pencils of this side are consumed, the rod C C has descended so far that its projecting head, K, strikes the long lever, M M, the other end of which raises the pin, E F, so bringing the other clutch into action. The electric arrangements, Fig. 25, are as follows: The magnet, S, is wound with a few turns of thick wire, and with many turns of fine wire. The cut-out (or cut-in) magnet, M, is wound with coarse wire only. The upper carbon-rod is connected electrically to the frame of the lamp, whilst the lower carbon, insulated from the frame, is joined by a wire (not shown in the figure) to the negative pole. The current entering at + P passes first round the coarse wire on S, most of it going through A and B (which are in contact), and on to − P; but a little of it, after traversing the coarse wire coil, turns back along the fine wire coil and goes by this by-pass route to B and − P. As a result, the armature is strongly attracted, and the lever, M N, descends, causing the carbon-rod to drop. This now opens another route for the current. Starting at + P, some of it will flow through M to the frame, thence through the upper and lower carbons and so to − P. This current will attract the armature, A, and break the contact between A and B, breaking the coarse wire circuit through S, leaving the fine wire path still available. Consequently S loses most of its power, and the spring + pulls up the lever M N, so striking the arc. The shunt-circuit (fine wire) through S is still at work, and continues to operate the feeding, increasing as the resistance of the arc lengthens.

The present attempt to furnish a classification of the various mechanisms, electrical and mechanical, of the arc lamp, is probably extremely imperfect, but it may at least claim to supersede the old and ludicrous division of lamps into "monophotal" and "polyphotal.' In conclusion, it may be pointed out that there exists a curious sort of family likeness between the several members of the three species of lamps most in use. The rack-train lamps, which may be considered as the prevailing continental type, are for the most part, in their design and construction, essentially clockmakers' lamps; they have a horological aspect. The clutch lamps so universal in America have a sort of sewing-machine look, the working parts being only finished where necessary for actual work, all else being left rough or merely painted over. The clutch-wheel lamps favoured by British inventors have, in contrast to these, a look as though they had been designed and constructed by a trained engineer; they are essentially engineers' lamps.

APPENDIX.

Sample of Filling up of Schedule.

SCHEDULE OF ARC LAMP MECHANISM.

Name of Lamp.—Thomson-Houston. Single arc.

Nature of Supply.—Constant current; *amperes* 9 8.

Resistances.—*Main-circuit coil*, 0·09; *shunt*, 279; *cut-out*, 0·85 *ohms*.

A	*Driving power* ...	Gravity on upper carbon-rod.
B	*Striking*	Main-circuit electromagnet attracts lower end of see-saw, lifts clutch.
b	*ditto adjustment*	(1.) Special resistance-coil shunting main-circuit coil. (2.) Spring on tail of clutch.
C	*Feeding*	Shunt electromagnet attracts upper end of see-saw, lowering clutch.
c	*ditto adjustment*	Same as *b*.
D	*Moderating*	Air dashpot on horizontal tail of see-saw.
E	*Replacement*	None required.
F	*Focussing*	None.
f	*ditto adjustment*	None.
G	*Change-over*	None.
H	*Cut-out*	Insulated contact on lower end of see-saw, pulled over by shunt-coil, and puts cut-out resistance as shunt from + to − terminal.

BOARD OF TRADE ENQUIRY.

Major Marindin, C.B., C.E., on behalf of the Board of Trade, opened an enquiry at the Westminster Town Hall, on Wednesday last, for the purpose of hearing, on the part of a number of electric lighting corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

The first case that came on for hearing was that of the London Electric Supply Corporation, Limited, who were represented by Mr. Pember, Q.C., Mr. A. K. Lloyd, and Mr. J. C. Graham, instructed by Messrs. Deacon, Gibson, and Metcalfe. The application of the corporation was opposed by Mr. Moulton, Q C., and Mr. R. S. Wright, instructed by Mr. Sidney Morse, on the part of the Chelsea Electric Light Company and the Electric Power Storage Company.

In opening the case for the London Electric Supply Corporation, Limited, **Mr. Pember** said that the authorised capital of the Corporation was £1,250,000, the subscribed capital was over £800,000 the paid-up capital, £585,000; the sum that the company had already expended on the prosecution of their works was £430,000 odd, and therefore they had on hand of actually paid-up capital over £150,000. He mentioned these figures merely to show that the inspector had to deal with a company which was financially very large, very powerful, and thoroughly substantial. He would presently give a little more in detail the nature of the machinery and buildings that were in course of erection, from which it would be seen that the company had not only got money, but that it was being spent in a wise and farseeing way. The company began operations by buying out the station known as the Grosvenor Gallery—in other words, by buying out what they called Sir Coutts Lindsay and Co., Limited. From that station they supplied—in a manner which would be detailed by the witnesses—something like 33,000 electric lights. They had gained in the course of the business that had been conducted there—a business which had afforded them very great insight into the method of supplying electricity for private, domestic, and public purposes—considerable experience, and he might say at once that it led them to the absolute conclusion that it was not expedient to have generating stations in populous neighbourhoods. Their intended system was the very opposite of that. They proposed, instead of having a generating station in each locality of London for the purposes of supply, to have one large station at Deptford, in Kent. From that station they proposed to have trunk mains running into London along the railway embankments and across the parapets of the bridges, with high-pressure currents; while in London itself it was intended to lay distributing mains along the streets, establishing local stations for converting the current and supplying light to private consumers by means of ordinary wires carried into their houses. There was a very sharp line of demarcation between that system and the one which he believed all those who were competitors to them adopted, and was identical with that which had been carried on at the Grosvenor Gallery station. The area of the provisional order which they asked for was undoubtedly a large one, but if it was compared with the one originally asked for it would be seen that several parishes had been struck out.

Mr. Moulton requested that the names of the parishes now omitted from the original plan (a sketch map of which was handed to the inspector) should be at once read.

Mr. Pember said they were as follows: St. Mary Abbots, Kensington; St. John, Hampstead; St. Mary, Islington; St. Leonard, Shoreditch; St. Luke; St. George-in-the-East; the Whitechapel district; St. Mary, Lambeth; and St. George-the-Martyr, Southwark; thus leaving as their area of supply the parishes of St. Martin-in-the-Fields; St. Margaret and St. John (united), Westminster; St. James, Westminster; St. George, Hanover-square; Chelsea; Paddington; St. Marylebone; St. Pancras; St. James and St. John (united), Clerkenwell; the Strand district; the St. Giles' district; the Holborn district; the City of London and the Liberties thereof; and the extra parochial places of Lincoln's-inn, Gray's-inn, and the Inner and Middle Temple, all in the county of Middlesex; the Greenwich district, in the county of Kent; St. Mary, Rotherhithe; St. Mary, Newington; St. Mary, Bermondsey; the districts of St. Olave, St. Saviour, and Christchurch, in Surrey. That gave the area of the order, which would be clear to everybody. There was one point in connection with it to which he wished to call attention. They did not ask for any exclusive grant of the districts over which their area extended. They did not oppose competitors. They were quite ready to allow the Board of Trade to grant an order to anybody else within the limits of the area over which they sought power. That being so, it seemed to him, and he could not help thinking that Major Marindin would agree with him, that there were two main questions of principle involved in their case. The first one he would formulate in this way: was it advisable to grant a large area to any one company? Secondly, was it advisable to give to more than one company powers over the same area? They, of course, answered "Yes" to both questions. He would at this point suggest that Parliament obviously intended that there should be competition. He remembered very well Mr. Stanhope's Committee of 1882, at which they discussed the question of competition *versus* a regulated monopoly, and he recollected that the theory of a regulated monopoly, such as was the case with gas companies, was rejected, the committee electing to leave the matter open to competition, and it was for that reason that they fixed no maximum price for electricity in 1882. If that was the principle upon which Parliament proceeded, it would be obvious that the Board of Trade should be open, at all events, to consider the question of unlimited competition in an area. If the question were answered in the affirmative by that body, it was clear that the first question would be answered in the affirmative, too, because if it was held advisable to give several companies power over the same area there was no harm in giving a company that worked over it as large an area as it might be able to cover. But he wished to point out that the possession of a large area upon which a company could employ its capital profitably—with the hope, in fact, of getting a large and remunerative business—was a very great encouragement to the application and investment of a larger capital, and surely when the money was well applied and wisely invested it induced cheapness in the article supplied by economical working. It encouraged a company to seek out the very best appliances from time to time, and generally offered an encouragement to enterprise, making it profitable to the public as well as to the company concerned. That was his view of the case. At all events this they were clear about, that there was nothing to prevent the Board of Trade from giving effect to the view in the two Acts of 1882 and 1888. It had a perfectly free hand in the matter, and they hoped the Board of Trade would give effect to it. He thought that if Major Marindin saw the works of the company at Deptford, to which he (the speaker) advised him to pay a visit, he would admit that though they were large they were very compact, and that he would feel, as the speaker did, they were a thoroughly well-devised attempt on the part of a company that hoped to be one of the forces of electric light in London, and to do something analogous for the public to what the Gas Light and Coke Company did when they removed out of London—to the great relief of the community—their works to Beckton. In fact, he hoped that Deptford would become, so to speak, an electrical Beckton. Their works consisted of four double engines and dynamos, two of 10,000 h.p., and two smaller ones of 1,500 h.p. each. The two latter would be ready for use in the course of a month from that day. The first large one would be ready in the month of November, and the second in December. Those engines would be amply sufficient to give a constant supply of 230,000 lights, and it was not too much to say that the plant could be quadrupled very speedily if it were required. He believed he did not overstate the case when he said that the company on their present premises could, if they were called upon to do it, give a daily supply of a million lights. For the carriage of the trunk mains into London, they had a very simple and very wisely designed expedient. Instead of breaking up the streets as they came along, they had made an agreement with the South-Eastern Railway Company, with the Brighton Railway Company, with the London Chatham, and Dover Railway Company, and with the Metropolitan Railway Company for the carriage of the company's mains along their respective lines, and outside the parapets of their bridges, so that there would be no breaking up of the streets in the suburbs as the mains were brought into town. The mains would be brought in at Charing Cross, he believed, South Kensington, and at various other points. But this was a matter which he would prefer to leave to the witnesses. Suffice it to say that the mains would strike the streets of London at convenient places. The high-pressure currents would be converted into low-pressure currents at their stations, being thence distributed, as he had said, by the ordinary supply wires to the different private and other houses desiring to use the light. Let him say a word as to the relative advantages of their system and those of other systems. In the first place, there was the removal of the different generating stations out of town to one place in the suburbs, which was a very great boon to all the parishes to be supplied. There would be no noise of moving machinery on a large scale at several spots, there would be no smoke, no vibration, and no carriage of coal through the streets. As to the first three matters, very little need be said. It was obvious that the absence of the manufactory itself must be a great advantage to everybody, for he believed that it was conceded on all hands that there was a nuisance caused by existing stations in London. There was one, he believed, at Paddington, another at Jermyn-street, and a third at the Grosvenor Gallery, where the nuisance was proved to be very great. In fact, he did not go too far when he said that lawsuits in connection with the nuisance so caused had been avoided only by the fact so far as the company were concerned, that they had assured those who suffered from it that they were doing their very best to persuade the Board of Trade to give them the order and adopt their system. The community had therefore shown a certain amount of forbearance over what he hoped would be only a temporary inconvenience. As to the matter of coal, that stood on a somewhat different footing. He was told that if 200,000 people were supplied with the electric light—and a very moderate estimate indeed would be one light per head, which would make 200,000 lights—he was told that, if the electricity required to take that number of lights to London were manufactured there, 408 tons of coal, or thereabouts, would be required for their production daily. He would ask them to note that that quantity of coal was calculated on the assumption that no condensing engines were of practical use in such populous places as they were dealing with. Now, 400 tons a day would be carted in 200 loads. To that number would have to be added a certain number more for the removal of ashes and the carriage of oil and other things. Let them say that 10 at least would be added. That would mean an addition to the traffic in the streets of the heaviest class of vehicles, not to mention the obstruction caused by the unlading of the carts, and the destruction of the roads, which would not be inconsiderable. They had then to consider the question of coal storage, which would not be practicable to any great extent, and the consequence of that would be that it would leave the undertakers of the enterprise to live from hand to mouth, as it were, with the result that in the event of a heavy snowstorm or fog, or any other condition of things which would prevent the ordinary supply of coal coming with its accustomed regularity, there would be a great part of the parishes supplied with the light left in temporary darkness. Let him now turn to another advantage—the economy of production—which their system involved, and the consequent cheapness of price to the consumer under the spur of competition. First, there was the concentration of the plant and premises for the purposes of production, in itself no mean advantage. Their main station out of

Digitized by Google

London would be on cheap land, and would be an agglomeration of several small stations, with a collection of engines, dynamos, and other plant in one building. There would be facilities for the storage of coal, and there would be economy of management in the shape of labour, in the shape of space, and in the shape of plant. The ready substitution of one piece of machinery for another could be readily effected by the mere turning of a switch in case of any accident happening to one piece. Again, and this was a very important point, they got cheapness, facility, and regularity of the coal supply, because they had a large wharf on the banks of the river to which their own steamers could get up. He was told that, setting aside all other advantages, in this respect they would have an advantage in the price of their coal alone by having to pay only something like 12s. 6d. to 15s. a ton, whereas they had now to pay 20s. to 25s. a ton in one of the central parishes of London. Finally, they had plenty of space, and an abundance of water at command. There were other advantages peculiar to their mode of producing electricity, and from the method of distribution, not to mention the small loss of the electricity generated, which would be better explained by more scientific witnesses than himself. Mr. Ferranti, their electrician, would explain the advantages of the continous current over the storage system which depends on the use of accummulators.

At this stage of the proceedings, a specimen of the mains which the company propose to use was handed in. They consist of an inner and outer copper tube, of about 2¼in. in diameter, the current having to pass up the inner and down the outer tube, the outside of which is carefully insulated.

Mr. Pember, continuing, said it would be plain that by the use of these mains the breaking up of the roadways was reduced to a minimum. While on this subject, he wished to add that they were perfectly willing to co-operate with any other company that might be serving the same district as theirs, so as to secure a joint opening of the streets from time to time, and thus prevent the multiplication of the process. Their system of distant transmission had been thoroughly well tested, and 30 miles were found to be a perfectly safe distance for transmitting electrical energy. But, of course, the distance over which their currents would be transmitted was far less than that. He thought it was now necessary to notice the other orders, and the attitude of those who sought them, as well as that of the vestries, to the London Electric Supply Corporation. Having enumerated the various companies who are asking for areas to light, he went on to say that the list of orders asked for he would dismiss by saying that the company only opposed them generally, having nothing to say against them, or to show how much better the company's system was than other people's. The method of other companies did not concern the London Electric Supply Corporation except on one condition, and that condition was in the event of the Board of Trade saying only one company should be allowed in one area. If that were to be the rule guiding the Board of Trade, then the London Electric Supply Corporation would oppose them all equally. They said that their system was the best for the supply of London, and if the system of competition were adopted, and one or more companies were allowed to go over the same area, this company were so thoroughly confident of the conditions and the terms they gave that they did not fear the presence of any number of other companies in the field. He found that in the parish of St. Martin-in-the-Fields the Metropolitan Company asked for a special Act, which he believed was to be brought before them for the purposes of that enquiry as a provisional order. Then the Electric Power Supply Company asked for powers in St. Martin-in-the-Fields, and so did the Westminster Power Corporation. (A voice: "The Westminster Power Corporation have abandoned that.") With regard to St. Margaret's and St. John's, Westminster, any definite action was postponed until after the Board of Trade enquiry. Then cames St. James', Westminster, in which the Metropolitan Electric Supply Company had asked for a special Act for it, as well as for St. Martin-in-the-Fields. The Westminster Electric Supply Company were there also. The vestry there assented subject to certain amendments, which, of course, had to be discussed. In St. George's, Hanover-square, he found that the Metropolitan, Chelsea, and Westminster Companies were all competing with them. In Chelsea they found the Metropolitan and the Chelsea competing with the existing order. The parish there agreed. In St. Marylebone they found the Metropolitan Company against them, and there the vestry withheld its assent. When they came to the Strand they found the Metropolitan, the Electric Power and Storage competing against them. (A voice: "Westminster has withdrawn.") The Strand dissented. In St. Giles they found the Metropolitan against them, the vestry assenting with conditions. In Holborn they again found the Metropolitan, and again the vestry assented with some slight condition. In the City of London they found the Metropolitan once more, and the City dissented. In the Clerkenwell district they had no competitor, and the local authority assented with conditions. In Rotherhithe they had no competitor, and the parish assented with conditions. In Lambeth the Metropolitan cropped up again, and the parish had issued a formal objection. There were two parishes—St. Mary's, Bermondsey, and St. Olave—where there were no competitors, and the authorities assented conditionally, and lastly there were St. Saviour's and Christ Church, where they found the Metropolitan, and where the local authority assented.

Major Marindin: Conditionally or absolutely?

Mr. Pember: Absolutely, I think. He must ask to go a little through the objections raised, and for that purpose he would take a typical parish or two, and by those means the general scope of the objections would be made clear. The first objection he would like to mention was one which he hoped the Board of Trade was not in the least likely to entertain. It was that the 42 years during which the companies were to be allowed to have enjoyment of their order, and which was settled by the legislation of 1888, should be cut down to 21 years, which had been previously settled by the Act of 1882. He thought that Parliament and everybody concerned had come to the conclusion that 21 years was a great deal too short a period, and that the electric lighting enterprise had been greatly crippled by the Act of 1882. The committee appointed by the House of Lords, and presided over by Earl Camperdown, in 1886 had such overwhelming evidence as to that fact that the Act of 1883 was the direct outcome of it, and considering the great retardation in the development of electric lighting, he did not think that Parliament or the Board of Trade would hark back to the 21 years' limit. He could quite understand a local authority desiring to get hold of such property on easy terms. He would select the objections raised by the parish of St. James', Westminster, which were fairly typical ones.

Mr. Moulton asked that the objections should be put in.

Mr. Pember said that he would hand them over to the opposing counsel in the course of the day. The first objection had reference to the power of the company to transfer their undertaking. It was certainly an open question whether undertakers under a provisional order could or could not transfer their undertaking. He saw in the legislation of 1882 and 1888 no express power enabling them to do so. He saw clause 11 of the Act of 1882 pointed to the notion that they were to be allowed to transfer an undertaking providing the Board of Trade consented. It was a matter, at all events, it seemed to him, not for the local but for the supreme authorities to determine—namely, the Board of Trade—and they were abundantly safeguarded against any improper transfer. The next thing that he noticed with regard to the Vestry of St. James', Westminster, was that they asked for the insertion of a clause requiring them to satisfy the Board of Trade as to their financial responsibility. He should have thought that the Board of Trade, until they were satisfied of what was called their responsibility, or their substantial power to carry out what they intended, would not give the company an order at all. The company did not blink any enquiry into their financial position. It was as sound as that of any company could be. Another suggestion made was that the parish asked that the undertakers should provide in some way a deposit of money for the satisfaction of the Board of Trade, presumably as a guarantee that they would carry out the work. He felt to treat that matter as a question of degree. If it were a question of depositing, say, £10,000 or £20,000 in respect of the whole area, to be repaid in the manner which the parish might indicate, he did not know that his company would offer any serious objection to it. But if it were to go much beyond that figure, if it were to be anything like such a sum as had been hinted—about £5,000 for every parish concerned, for example, and there were about a dozen or twenty parishes—that would amount to a serious sum of money, and he did not think it wise to recommend the Board of Trade to recommend such a suggestion. It would be against public policy to lock up such a sum of money, which might be very well expended on the furtherance of the order itself. The next point he noticed was that it was desired to insert a provision prohibiting the placing of any electric line above ground, along or across any street without the express consent of the local authority. He thought that was a point that ought to be determined by no one but the Board of Trade, who would consider it on its merits. The next amendment he cared to notice was that the distributing-boxes which were to be placed in the street should be of a size and pattern to be approved by the local authority. To that his only objection would be that it would be giving the local authority too much power in a matter in which they might not be able to form a judgment. Coming to the question of overhead wires, he said that was a matter with which they must deal with considerable care. The proposal was that words should be inserted to the effect that the order was to confer no powers to place overhead wires. If those were the exact words he would have, he thought, no objection; but he would strenuously object to the words going one bit further. At the present moment they believed, in common with a great many other companies, telegraph and telephone companies, that they had the common law right of owners and occupiers to carry the wires at a sufficient height as to take them from house to house. It was common knowledge that such wires were carried all over London, and they would strenuously object to any words being inserted which would have the effect of controlling or limiting their present legal rights in the matter. The next point was that the undertakers might forthwith and should be bound to lay their mains compulsorily at any time after the expiration of 1½ years after the commencement of the order. That was a question of degree. The next point was in section 15, which dealt with the failure of the undertakers to lay down mains, etc., in which case the order might be revoked, and the words as to the whole or part of the area were substituted for the words as to whole or part of a street.

Mr. Moulton observed that that was a most serious point in the order.

Major Marindin: If you fail to supply any particular street, the order may be revoked as to whole or part of the area in respect of which default shall be made. That is as I understand it.

Mr. Pember said that the next proposal was the substitution of courts of summary jurisdiction in lieu of the arbitrator appointed by the Board of Trade. That had reference to clause 16. He could not help thinking that an arbitrator of the Board of Trade was a far better person than a police magistrate for dealing with any such questions as might arise under the order. Clause 18 provided that, "where any such requisition is made by the local authority, it shall not be binding on the undertakers, unless at the time when such services is effected, or within 14 days thereafter, there be tendered to the undertakers (it required by them) an agreement executed by the local authority for binding them to take for a period of three years at the least a supply of electricity for lighting such public lamps in the street, or part of a street, in respect of which such requisition is made as may be under their management or control, and to pay for the same an annual sum not exceeding 20 per centum per annum upon the cost of providing and laying down the required distributing mains, and any other mains or additions to existing mains which may be

Digitized by Google

necessary for the purposes of connecting such distributing mains with the nearest available source of supply." To that was added: "Provided that in streets where the undertakers have distributing mains laid for the purpose of general supply it shall not be necessary for the local authority to guarantee any annual sum except the cost of the electric current actually consumed by them." Now, as he understood it, the requisition which that particular parish—St. James', Westminster—had made upon them was that they should be compelled, if it were required, to lay in those mains and to give the supply in street lamps without that guarantee of 20 per cent., notwithstanding that clause 43 provided the price to be paid by the local authority for the public lamps should be settled between the local authority and the undertakers. It was obvious to everybody, he believed, that the least remunerative part of the business either of an electrical company or a gas company was the supply of the lights to the public streets; and he thought it would be, to say the least of it, very hard if the local authority, in a street or part of a district where there was nobody caring to take the electric light for the purpose of private consumption, were to call upon the promoters to lay mains down that street for the purpose of lighting the lamps without some consideration. It was true that in section 43 it could be settled by agreement between the parties, but it was equally true that unless street lighting were supplemented by private consumption, electricity would not pay at all. As to the insertion by the local authority of testing places and the necessity for keeping instruments for making tests, he did not think that they would object to that. As to clause 36, where it was suggested that where there was ground for apprehension of their supply being interfered with, owing to the defective conditions of the consumers' fittings, there should be a right of appeal to a court of summary jurisdiction. There, again, he thought that any such dispute would be better settled by an ordinary Board of Trade arbitrator. Under clause 38 it was proposed to increase the distance within which street lamps were to be lighted from 50 to 75 yards. That the company readily acceded to. In clause 39 they had a proviso intended to protect them against responsibility from default which did not arise from negligence, for which it was said there was no necessity. But he did not agree with that view. The next amendment of importance had reference to the 56th section, relating to the exemption of generating stations from "The Metropolitan Building Act, 1855." They asked that the rules which governed that Act should not be made applicable to any building of the company three miles from St. Paul's Cathedral, and used by them wholly for the generation of electricity. After alluding to some other minor objections, he said he would ask the inspector to consider the different objections, and if they were not sound, to disregard them. At the same time, if they were sound he ought to report to the Board of Trade to that effect, and the Board would refuse or give to the company their order, either absolutely or conditionally, as the case might be. But he would ask the inspector to consider that the dissent of any of those local authorities, or any objection conditionally on the part of those local authorities, was in the nature of a veto, and it was obvious that if they looked at section 2 of the Act of 1888 no such veto was intended to be given. By the Act of 1882, the local authorities had no right to assent or dissent to an order. The Board of Trade had to give their notice that they were to give an order. The question of their anterior assent or dissent was not mentioned. In 1888 there was a modification of that to the extent that no provisional order should be granted by the Board of Trade, except with the consent of the local authority, unless the Board of Trade, in any case, were of opinion that, having regard to all the circumstances of the case, such consent ought to be dispensed with in such case. That made it perfectly clear to his mind that the Board of Trade had the undoubted right to grant the order, or any other order, against the wishes of the local authority if they thought that the wishes of the local authority, either as a matter of principle or as a matter of detail, were unreasonable.

Mr. Goldney (the City Remembrancer) intimated that the City objected to the terms of both companies which proposed to take the City into their area.

The enquiry was then adjourned for a short time.

After the company reassembled,

Lord Crawford and Balcarres was examined by Mr. R. S. Wright in support of the London Electric Supply Corporation's claims, and in the course of his examination admitted that the experience that he had gained at the Grosvenor Gallery led him to the conclusion that the electric light could be better supplied from a large central station in the suburbs than from many small stations in a populous neighbourhood. It had many advantages to commend it. It obviated the nuisances of noise, smoke, and vibrations from the working of machinery, and many others. A large area could be undoubtedly worked by one company. He gave it as his emphatic belief that the development of electricity as a motive power would completely throw into the shade its development as a lighting medium. He endorsed the remarks of Mr. Pember in his opening statement as to the amount of the company's capital, and the character and extent of the works at Deptford. The distance which electricity could be transmitted for their purposes was to be counted by many miles, and it could be done with absolute safety to the public. Being at Deptford, the company could save greatly on its coal account, while considerable economy in the management could be effected. He did not know that it was an advantage to the undertakers to have one or more competing schemes in the same area at the same time, but it would certainly benefit the public. By the mains that they proposed to lay there would be no yawning chasms in the roadways which were caused by the laying of gas mains, for they would be quite satisfied to lay their tubes about 10in. to 12in. below the surface of the ground. There was no reason why two or more of these mains should not be laid down in close proximity to one another.

Cross-examined by Mr. Moulton, the witness said he saw no objection to two or more companies working in the same area. There were certain objections on scientific grounds as to testing, distributing-boxes, and so on, which he was prepared to leave to the Board of Trade to decide as between them and their competitors. He did not think that every method that the company were adopting was open to any other company to take up. The advantages which they derived from their removal were chiefly in connection with their having chosen a site for their works conveniently situated near the river, which would result in many economies and facilities not otherwise attainable. Their plant would supply 230,000 lights. The statement with regard to the procession of 200 carts a day was taken from their experience at the Grosvenor Gallery. They proposed to distribute in their mains at a pressure of 2,400 volts. Their second transformers were in the customers' houses.

Cross-examined by the City Remembrancer (Mr. S. Prior Goldney), he further deposed that they had got applications for from 70,000 to 100,000 private lights. They included the City in the area because they hoped to do good business. He could not say that they had made any special calculation as to the amount of profit to be made from the City or any other place. It was impossible to put in any allocation of capital to be spent for the City or any other place. When fixing upon the capital, they decided to have a million to begin with. They then said they would have £250,000 extra in order to provide extra power when that power was required. That capital was practically untouched. They had got no debts. If they got this order he thought they would go to the public for more capital. They struck out the places that had been mentioned simply as a matter of convenience.

The **Remembrancer**: Convenience of supply or convenience of cash?

The **Witness** thought that they put aside altogether any convenience of cash. There was no use worrying about that. To questions subsequently put to him, the witness said that St. Margaret's was abandoned from the very first, because they never intended to work there. As to St. Mary Abbots, Kensington, they were offered by the vestry to light three or four turnip fields and the Kensal Green Cemetery, and he declined to go there.

Major Marindin: As a matter of fact, the Kensington Vestry has split their parish up into five or six areas and given those areas to different companies. The part that this company was given was not likely to be very remunerative. That was the reason which Lord Crawford gave.

The **Remembrancer** next asked why Paddington was abandoned.

The **Witness** replied that they were obliged to abandon certain things, and they abandoned what was most unfavourable to themselves. St. John, Hampstead, and St. Mary, Islington, were taken off because they thought their area too large. The same answer was given with regard to the remaining parishes abandoned. He did not say that a million and a quarter of money would be sufficient to absolutely suffice for the area sought. If they were to light the whole of London, it would require five or six millions. He contemplated lighting the whole of the area as it originally stood, but not by this order alone. Next year or the year after they contemplated getting a further order. He did not see why the City should be eliminated from that particular order.

The Court then adjourned.

LEGAL INTELLIGENCE.

IN RE THE MIDLANDS ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

This was a motion on Saturday last, under section 35 of the Companies Act, 1862, to rectify the register of shares of a company by striking out the name of Mr. Arthur Chamberlain, of Birmingham, as holder of 2,074 £10 ordinary shares, on the ground that they had been issued at a discount, and, therefore, under an *ultra vires* contract. The question raised was whether the contract under which the shares were issued really was a contract to issue those shares at a discount, or to issue them in consideration of a debt of the amount of the nominal value of the shares. An agreement was entered into, dated April, 1887, between Mr. Arthur Chamberlain and the company, which provided for the sale of certain concessions to the company. The agreement also provided for advances being made by Mr. Arthur Chamberlain on account of the company, payable on demand by the company to Mr. Chamberlain, with interest at the rate of 15 per cent. per annum from the dates of the advances, with an alternative that Mr. Chamberlain should have the option of taking shares, to be paid for by the advances, without interest, but with the addition of 15 per cent. on the money advanced. The amount advanced to the company by Mr. Chamberlain to the end of 1887 was found to be £18,041. 5s. 11d., and £2,706. 3s. 9d., or 15 per cent., added to that sum brought the amount for which Mr. Chamberlain was to have the option of receiving shares up to the aggregate sum of £20,747. 9s. 8d. A second agreement was made between the parties in April, 1888, which recited that Mr. Chamberlain had elected to accept in satisfaction of £20,740, part of the aggregate sum, 2,070 fully paid-up shares, leaving a balance due to him of £7. 9s. 8d., and provided that, as soon as that agreement should be registered, that number of shares should be issued to him. That agreement was registered, and the shares issued to Mr. Chamberlain, on whose behalf this motion was made to determine whether the transaction was legal. It was clear that a year's interest was not due on the whole of the advances, so that £2,706. 3s. 9d. was more than interest at 15 per cent per annum.

Mr. Birrell appeared for Mr. Arthur Chamberlain.

Digitized by Google

Mr. R. J. Parker, for the company, submitted that the whole agreement of April, 1887, was to be taken together, and the sum of £20,747. 9s. 8d. was therefore a debt due partly for advances and partly for purchase-money; and the shares were therefore issued for an equivalent debt, equal to their nominal value.

Mr. Justice North considered this argument more ingenious than sound, for the parties by their agreement had shown that the transactions were distinct, and had themselves severed them. The nominal purchase-money, he said, was more than the advances and interest. The shares were therefore issued at a discount, and it followed that the contract to issue them was void.

COMPANIES' MEETINGS.

EDMUNDSONS, LIMITED.

The statutory meeting of this Company was held on their premises, 19, Great George-street, Westminster, on the 28th March.

Mr. John R. Wigham, J.P., chairman of the Company, occupied the chair.

The **Chairman** congratulated the shareholders on the satisfactory position of the Company. He stated that a larger amount of trade had been done since the acquisition of the business by the Company dating from July last than in the whole of any year during which the trade had been carried on by their predecessors, and that the prospects of the Company, in view of the advances that are being made in electric lighting, are exceedingly encouraging. He also mentioned that the shares had been all taken up within a few days after the issue of the prospectus, and that they are held exclusively by the customers of the Company and by the Directors, many of the former being amongst the largest consumers of electric light in this country.

The outgoing Directors were all re-elected.

CITY NOTES.

West Coast of America Telegraph Company.—The receipts of this Company for March were £5,950.

Direct Spanish Telegraph Company.—The estimated receipts for March were £2,129 against £1,900.

Telephone Company of Austria, Limited.—This Company has declared the usual half-yearly dividend to 31st ult. on their preference shares at the rate of 6 per cent. per annum.

West India and Panama Telegraph Company.—The estimated receipts for the half-month ended March 31 were £3,714, against £3,714. The December receipts, estimated at £5,149, realised £5,229.

Direct Spanish Telegraph Company.—With reference to the taking over of the Submarine Telegraph Company by the Government, the Direct Spanish Telegraph Company, Limited, announce that the acquisition has nothing to do with this Company.

Cuba Submarine Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during March was 5,992, estimated to produce £4,500, against 4,919 messages producing £3,835. The receipts for December, estimated at £3,500, realised £3,508.

Anglo-American Telegraph Company, Limited.—This Company has declared an interim dividend for the quarter ending March 31, 1889, of 12s. 6d. per cent. on the ordinary and 25 per cent. on the preferred stocks, less income tax, payable on the 1st of May to the stockholders registered on the books on April 1, 1889.

Oriental Telephone Company, Limited. — The report of the Directors of this Company, for the year ending December 31 last, states that the revenue account shows a balance at credit of £6,652, which has been transferred to profit and loss. Including the sum of £3.603 brought forward from the previous year, the amount available for disposal is £10,254, which the Directors recommend should be dealt with as follows: To place £2,500 to a reserve fund, to apply £3,000 in final extinction of preliminary expenses, to write off £341. 4s. 8d. for depreciation of stores and balance cost of reconstruction of the Rangoon exchange, and to pay a dividend of 3 per cent., free of income tax, on the paid-up capital of the Company other than the vendors' shares, carrying forward £686.

Companies for the Month.—The following electrical companies have been registered during the past month:

Bath Electric Company, £10 shares	£25,000
Corinthian Electro-Medical Battery Company, Limited, £1 shares	25,000
Devon and Exeter Turkish, Medical, and Swimming Baths Company, £1 shares	7,000
Halifax Mutual Electric Light and Power Company, Limited, £5 shares	20,000
Laing, Wharton, and Down, Construction Syndicate, £100 shares	40,000
Nottingham Electric Light and Power Company, £10 shares	100,000

Eastern Extension, etc., Company, Limited.—The report of this Company for the half-year ended December 31 states that the gross receipts, including Government subsidies, amounted to £238,854, against £232,660. The working and other expenses, including £23,883 for cost of repairs to cables and expenses of ships, absorbed £71,519, against £69,570, and the net profit for the half-year, with £47,903 brought forward, is £166,101. One quarterly interim dividend of 1¼ per cent. was paid for the half-year, and it is proposed to distribute another of like amount, making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 3s. per share, or 1½ per cent., making a total distribution of 6½ per cent. for 1888. The balance of £66,101 has been carried to the general reserve fund, which, after being credited with the interest on investments received during the half-year, and debited with the cost of the partial renewals of the Java-Australian cables off the Lombok Straits, amounting to £18,987, now stands at £690,455.

Electrical Power Storage Company, Limited.—The report of the Directors of this Company states that the gross profit for the year is £13,273. 15s. 3d., which includes all royalties and receipts, the bulk of this profit being derived from the manufacture of storage batteries and special apparatus in connection therewith. The expenditure for the year, including debenture and other interest, etc., is £11,709. 3s. 8d., and the balance, added to the amount standing to the credit of profit and loss, makes the sum of £8,372. 13s. 6d., out of which the Directors would recommend a dividend were it not that the increasing volume of business demands a larger working capital, and the best method of securing this has been, and is, a subject of anxious consideration by the Directors. During the year under review there was a considerable increase in the Company's business, while, as compared with the corresponding period of the year 1888, the orders received this year up to date have already nearly doubled. To meet this rapid growth of business, it has been necessary to make a considerable outlay on the Millwall Works, and to increase the staff. This additional outlay amounts to £1,827. 3s. 6d. Among the many new electric light installations employing storage batteries may be mentioned the Lyric Theatre, where a 1,000 16-c.p. E.P.S. battery is erected; the London Joint-Stock Bank; the private residences of Sir Henry Meux, Bart., J. Fletcher Moulton, Esq., Q.C., Alfred de Rothschild, Esq., Dr. John Hopkinson, F.R.S., and the Royal Arsenal, Woolwich. The new form of battery, known as the "1888" type, continues to give satisfaction. A number of scientific and technical institutions have adopted accumulators—viz., the Central Guilds of London Institute, Millard Laboratory, Oxford; Cavendish Laboratory, Cambridge; University College of Wales, Cardiff; Heriot-Watt College, Edinburgh; Queen's College, Cork; and the University of Japan, Tokio. A gold medal was awarded the Company at the Brussels Exhibition for their exhibit of storage batteries and accessory apparatus. Central station lighting, which the Directors have regarded as ultimately the main source for the use on a commercial scale of storage batteries, is at last beginning to attract the serious attention of the public, and it is hoped that many of the applications for provisional orders now before the Board of Trade may be granted and confirmed by Parliament during the current year, as, until that result is attained, the full effect of the alteration of the law by the Electric Lighting Amendment Act of 1888 cannot be felt. The only company in the metropolis which possesses the requisite Parliamentary powers is the Chelsea Electricity Supply Company, under 50 Vic., cap. xviii., with which company a contract has been made for the supply of a large accumulator battery for its central station and sub-stations. The Chelsea Company will work its central station on the distribution system of the E.P.S. Company, and will supply light during the present month. Batteries have also been furnished for central stations in various parts of the kingdom. Accumulators for train lighting have been in demand. Extensions have been made to the lighting plant of the London, Brighton, and South Coast and Great Northern Railways, and batteries for this purpose have also been furnished to the Midland, London and North-Western, and Taff Vale Railways, and South-Western Railway of Russia. For ship and yacht lighting, a new type of accumulator has been designed, and has been supplied to the British navy, the Italian and Danish navies, and to yachts, among which may be mentioned the "Mohican," "Wanderer," and "Torfrida." The lighting of 40 omnibuses of the London General Omnibus Company is carried out by means of E. P. S. accumulators. In surgical batteries a new use for accumulators has been found, and a portable type battery has been made from which current is supplied to cauteries, induction-coils, motors and lamps, and to give special facility for recharging in London, Messrs. Coxeter and Sons, the surgical instrument makers, have established a charging station in Grafton-street, W.C. For the propulsion of electric tramcars a large order has been received from the Electric Traction Company for storage batteries for six cars for working on the Barking line. An interesting experiment has also been made by Mr. Sandwell in propelling tram cars by batteries carried on a separate truck or bogie. In electric launches, worked from storage batteries, progress has been made, as E.P.S. batteries are used in the "Maldon" and the "Viscountess Bury," the latter a boat 65ft. long by 10ft. beam. E.P.S. accumulators are also employed by Mr. Radcliffe Ward in his method of propelling vehicles on ordinary roads by electricity. Throughout Europe the advantages of the use of storage batteries are gradually being realised, but several causes have tended to delay their general adoption. This year the Directors hope the amount of royalties will be substantially increased, as the various companies and firms with whom arrangements have been made to manufacture E.P.S. batteries under royalty have completed the erection of their factories. These are to supply the batteries in Germany, Austria, Hungary, France, Russia, Finland, and the Scandinavian countries. The Electrical Accumulator Company of New York is pushing the business vigorously in all directions on the American continent, and a pamphlet published by that company, showing how successful it has been in establishing its patent rights in the United States, will be read by the

Digitized by Google

shareholders with much interest. The retiring Directors are Sir Daniel Cooper, Bart., and J. Irving Courtenay, Esq., who, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, and Co., also offer themselves for re-election.

NEW COMPANIES REGISTERED.

Corinthian Electro-Medical Battery Company, Limited.—Registered by C. Doubble, 14, Serjeants'-inn, Temple, E.C., with a capital of £25,000 in £1 shares. Object: to manufacture, buy, sell, let or hire, and deal in machines and apparatus for the automatic delivery of goods, etc. The first subscribers are:

	Shares.
E. L. Lovell, Springfield, Barnes	1
F. T. Rushton, 57, Sackville-road, Hove	1
A. Bellingham, 23, Albert-square, S.W.	1
C. A. Bury, Highfield House, Leeds	1
G. M. Duncan, 19, Gordon-street, W.C.	1
C. Spencer, 47, Durham-road, Manor-park	1
C. J. Downie, Canty Bay, North Berwick	1

The number of Directors shall not be less than two nor more than five. The first are E. L. Lovell and F. T. Rushton. Qualification: the holding of £100 stock. Remuneration as may be determined in general meeting.

Halifax Mutual Electric Light and Power Company, Limited.—Registered by C. Doubble, 14, Serjeants'-inn, Temple, E.C., with a capital of £20,000 in £5 shares. Object: to generally carry on the business of electrical engineers, manufacturers, contractors, and electric lighting, and to acquire concessions from or with governments, municipal or other authorities, for the supply and production of same. The first subscribers are:

	Shares.
F. H. Bowman, West Mount, Halifax	1
J. Asquith, Old Market, Halifax	1
J. Haley, Cleckheaton	1
M. Brown, Hipperholme	1
A. Fletcher, 71, Northgate, Halifax	1
G. A. Blackburn, 18, Northgate, Halifax	1
R. Needham, 9 and 11, Crown-street, Halifax	1

The number of Directors shall not be less than three nor more than seven. The first three subscribers to the memorandum of association are the first Directors. Remuneration to be determined in general meeting.

Planet Electrical Engineering Company, Limited.—Registered by F. T. Webster, 7, Great St. Helens, E.C., with a capital of £20,000 in £5 shares. Object: to carry on the business of an electric light company in all its branches. The first subscribers are:

	Shares.
R. C. Batley, Seaborough Court, Crewkerne	1
J. H. Newman, 2, Great George-street, S.W.	1
H. E. Moojen, 18, Broadway, Streatham	1
F. T. Webster, 7, Great St. Helens, E.C.	1
F. Iago, 2, Victoria-mansions, S.W.	1
J. Stuck, 2, Victoria-mansions, S.W.	1
A. L. Shepherd, 2, Victoria-mansions, S.W.	1

The Manufacture of Aluminium.—For the production of aluminium in France, the Societe Electro-Metallurgique has just been formed with a view to erecting extensive works at Forges (department of Tsere). Heroult's process will be adopted, which is fusing the rebellious metallic alloys by means of a metallic current, and separating the metal by electrolysis. Dynamos, each of 7,000 amperes and 70 volts, generate the current, and two vertical turbines of 300 h.p. yield the motive power. In addition to aluminium-bronze, the plant will produce all the alloys of aluminium, with the exception of such as become volatilised at the same temperature as aluminium. It is estimated that a daily production of aluminium alone of 300 kilos will be attained.

PROVISIONAL PATENTS, 1889.

March 25.

5093. **Improvements in electric batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

5095. **Improvements in the form and manufacture of the frames, plates, and cells of storage or secondary batteries.** Thomas Joseph Haslam, junr., of the firm of Wm. R. Box and Co., 105, Middle Abbey-street, Dublin. (Complete specification.)

5104. **Improvements in apparatus for communicating, by means of an electric current, with railway trains when in motion.** Albert Edward Lewis, 70, Wellington-street.

5116. **Improved electrical storage battery or accumulator.** Thomas Pease, 3, Kimberley-street, Princes Park, Liverpool.

5127. **Electric razor.** Ellis J. Davis, 65-66, Chancery-lane, London.

5131. **Improvements in transformers for alternating currents.** Alphonse Isidore Gravier, 6, Bream's-buildings, London.

March 26.

5140. **Improvements in the laying of underground conductors for the conveyance of electricity.** Sidney William Baynes, 4, Hallfield-street, Manningham, Bradford, Yorkshire.

5142. **Improvements in systems of electrical distribution.** Stanley Charles Cuthbert Currie, 6, Livery-street, Birmingham. (Complete specification.)

5152. **Improvements in electrical, gas, or other lamp globe or shade holder.** Elijah Atkins, 12, Cherry-street, Birmingham.

5176. **Improvements in or connected with electrical installations.** Elmer Ambrose Sperry, 1, Quality-court, Chancery-lane. (Complete specification.)

5209. **Improvements in electrical alternate current motors.** Martin Hamilton Kilgour, 226, High Holborn, London.

March 27.

5241. **Improvements in magnets, magneto-generators, and telephones.** Philip Middleton Justice, 55 and 56, Chancery-lane, Middlesex. (Elias M. Greene, United States.) (Complete specification.)

5251. **Improvements in generating and storing electric energy.** Rankin Kennedy, 46, Gibson-street, Hillhead, Glasgow.

5282. **An electric time indicator, with or without calendar.** Alfred Horace Gladwin, 77, Chancery-lane, London.

5293. **Improvements relating to apparatus for the distribution and conversion of electric currents.** Thomas Hammill Hicks, 45, Southampton buildings, London. (Complete specification.)

March 28.

5322. **Apparatus for obtaining readings from indicators placed at a distance by the agency of electric currents.** Thomas John Murday, 20, High Holborn, London. (Complete specification.)

5348. **Measuring and regulating electrical frequency and currency.** William Edward Ayrton, 2, Upper Phillimore-gardens, and John Perry, 10, Penywern-road, both in London.

March 29.

5377. **Improvements in electrical testing instruments.** Frederick King and William Phillips Mendham, Western Electrical Works, Narrow Wine-street, Bristol.

5391. **Improvements in the method of and appliances for insulating electric wires.** Hermann Aron, 6, Lord-street, Liverpool.

5407. **Improvements in fuses and cut-outs for electric circuits.** Arthur Cecil Cockburn and Henry William Handcock, 32, Gaisford-street, Kentish Town, London.

5423. **Improvements in conduits or supports for electric conductors.** Frank King, 47, Lincoln's-inn-fields, London.

March 30.

5509. **Improvements in electric arc lamps.** Herbert Ernest Fenner, 115, Cannon-street, London.

SPECIFICATIONS PUBLISHED.

1887.

4225*. **Electricity meters.** Hookham. (Amended specification.) 1s. 1d.

1888.

3672. **Electric circuits.** Edmunds. 8d.
5191. **Storage batteries.** Edmunds. 6d.
5704. **Switchboards, &c.** Raworth. 8d.

1889.

362. **Working metals by electricity.** Lake (Thomson.) 8d.
1401. **Generating electricity.** Dyer and others. 6d.
1677. **Electric switch.** Whittingham. 8d.
1892. **Electric motors, &c.** Boult (Serrell and another.) 8d.
2066. **Secondary batteries.** Paget. 6d.
2276. **Primary batteries.** Guitton (Sappey.) 11d.

NOTES.

Telephones at Milan.—A new central exchange will be shortly installed at Milan, in the Galerie Victor-Emmanuel. Lines will be run for 3,000 subscribers.

Naples.—A proposition has been made to the Municipality of this town for the establishment of an electric tramway consisting of five lines, of a total length of 14·7 kilometres.

Electric Automatic Box Company.—The company of this name has, it is reputed, amalgamated with the Automatic Trading Company, the latter requiring "an increase of capital."

Telephone to France.—M. Coulon, Director of Posts and Telegraphs (says the Paris correspondent of the *Times*), has directed experiments to be made, with a view to telephonic communication between Paris and London.

Elieson Electric Company.—Those of our readers who are interested should not forget the sale of this company s plant at Plashet Hall Works, Romford-road, Stratford, E., on Wednesday next at 12 (for one) o'clock.

Rome. — The Co-operative Telephone Company of Rome inaugurated the installation of electric light in the whole of its central exchanges and offices on the 4th of last month, in the presence of a large number of authorities.

Rotherhithe.—The clerk reported the receipt of a letter from the London Electric Supply Corporation, stating that they did not intend to proceed with the provisional order this session for supplying electric light in the parish.

Paris.—The electric light company for the supply of the district of Clichy, Paris, though yet in formation, has had a concession granted by the Municipal Council, and is negotiating for the purchase of a site for its central station in the Rue des Dames.

Arc Lights in Shaftesbury Avenue.—The large new premises adjoining the Café Monico, taken by a large clothing firm, are fitted with 35 Pilsen arc lights, and are to be run from the station in Holborn from a Waterhouse constant current dynamo.

Royal Meteorological Society.—At the next meeting of this society, to be held at 25, Great George-street, on Wednesday, the 17th inst., at 7 p.m., a paper will be read "On the Deaths caused by Lightning in England and Wales from 1852 to 1880."

Arc Station in London.—We understand that the central station for 200 Waterhouse arc lights in London we mentioned some time ago is progressing satisfactorily, and the engines are now being fixed. It is intended also to distribute power from this station.

France.—On the 13th ult. the President of the French Republic paid a visit to the Edison central station in the Palais Royal, where he was received by M. Am. Vernes, the chief engineer of the company. We are informed that M. Carnot expressed the liveliest satisfaction with the installation.

Distribution of Power in France.—A central station for the distribution of power by electricity has been installed at 18, rue Beaubourg, Paris, by MM. Tschierer and Fuchs, manufactures at Puteaux. A Corliss horizontal engine of 110 h.p., and two Gramme dynamos of 370 amperes and 110 volts are employed.

A Uniform for the Indian Civil Service.—The Government of India has fixed upon a distinguishing uniform for members of the Civil Service—such as the Survey, Postal, Telegraph, and other departments—when attached for service with troops in the field.

The Bell Telephone Patent.—In the Chancery Division of the High Court of Justice, on Monday, before Mr. Justice North, the action of the United Telephone Company, Limited, *v.* Siemens Brothers was disposed of, the parties having come to terms. The action was brought for an injunction to restrain the defendants from infringing the well-known Bell telephone patent.

China.—The Emperor of China having decided to introduce the electric light in his palaces, an engineer from Messrs. Siemens and Halske, of Berlin, recently arrived at Pekin with the necessary material. Before, however, this gentleman will be allowed to proceed with the work of installation, he will be required to demonstrate that the light is not obtained by supernatural means.

Overhead Wires.—In the House of Commons on Monday, Mr. Ritchie, in answer to Sir G. Campbell, said he had communicated with the President of the Board of Trade, who was considering the possibility of making regulations on this matter ; but no power could be given to local authorities to deal with it without legislation, and the Government did not at present propose to introduce a Bill on the subject.

Electric Motor Work.—Mr. Nell, writing from 16, Mark-lane, E.C., informs us that the Sprague Electric Railway and Motor Company, of New York, of which he has been acting as representative, have disposed of their patent rights. Mr. Nell, having large connections for this class of work, is now open to form an alliance or to take up the general agency of a responsible firm with a view to pushing electric motor work.

Electric Lighting of the British Museum.—In the House of Commons, on Tuesday, in reply to Mr. H. Gardner, Mr. Jackson said that it had been decided to extend the electric light to the British Museum, and to make the experiment of evening opening. Sir G. Campbell asked whether the promise had not been made that the first experiment in this direction should be at the Natural History Museum. Mr. Jackson said that it had not.

Electricity at Ipswich.—Messrs. Laurence, Paris, and Scott have recently been called in to light the library at Norwich. The same firm contributed some interesting adjuncts to the exhibition which was held last week at Ipswich. These included two electric motors, one of half horse-power, and another of four times that force, which was used to drive a lithographic press shown in working by Mr. Norman Adlard, of the Butter Market, Ipswich.

The Series Tramway.—We have received from the Series Electrical Traction Syndicate, Limited, a neat and well-printed pamphlet containing the collected "Opinions of the Press" upon their new undertaking at Northfleet. In this pamphlet, the article, with illustrations, describing the line from this journal is given at length. The article in another column is to be taken as impartial criticism to elicit more definitely the advantages or otherwise of this system.

Heavy Steel Casting for Deptford Engines.—A 75-ton ingot was successfully cast at the Parkhead Forge, says a Dundee paper on Saturday. It is the first of a set of

Digitized by Google

crankshafts for the London Electric Supply Corporation, Limited, and is 20ft long. The shaft into which it is to be forged is 26ft. long by 36in. diameter, being for the largest electric lighting machine in the world. The shaft, with a 12in. diameter hole through centre, will itself weigh 23 tons when completed.

Electric Parcel Cart.—At the end of our article on the electric omnibus, we mentioned that the Ward Electric Car Company were intending to build an electric parcel cart for an enterprising London tradesman (not Whiteley), which is to be run at a speed of 12 miles an hour, for delivery of goods in the suburbs. The cart is now in a fair way of completion. It is rather high in appearance, with three wheels—something like a tricycle—the two wheels being the driving wheels and the front one the steering wheel. The cart will be running on the roads in three weeks or so.

Davey-Paxman Engines.—The last of six handsome engines supplied by the firm of Davey, Paxman, and Co., of Colchester, will arrive this week at the Paris Exhibition, where they will be employed in supplying the electric light to the great world's fair. These engines, which are all fitted with Paxman's automatic expansion gear, and with very sensitive governors, range from 40 to 100 h.p., and are chiefly of the Girder type. In addition to these, six Colchester engines from the same firm will be at work lighting the Boulevards, and six more have been supplied to a French syndicate.

Church Struck by Lightning.—A terrific thunderstorm broke over Dartmoor on Saturday afternoon. Among other damage reported is the partial destruction of Walkhampton Church. The north-east pinnacle was struck by electricity and cast down, crashing through the roof upon the organ, at which the vicar's daughter a few minutes before had been seated. The sextoness also had a narrow escape. The destruction is great, but would have been more extensive had not the electricity travelled down the tower by the rainwater-pipe, which was twisted and melted into fantastic shapes, but it saved the tower.

Lighting in Ireland.—Ballymena is getting well abreast of the times in the adoption of electric light, several mills and workshops having been fitted up, Mr. C. C. MacCarthy, Dundalk, having in all cases carried out the installations. Mr. J. Gault has 15 lamps in his meal-mill, and a large number in his sawmill and coal stores; Messrs. Kave Bros'. foundry is lighted by 30 lamps, whilst over 400 are installed in the factory and bleach works of Messrs. J. H. and G. Bellis, Messrs. Morton and Co.'s flour-mill, Messrs. Raphael and Wolseley's handkerchief factory. Several private residences are also lighted.

Amateur Dynamo Making.—We have received from Mr. Alfred Crofts, of Dover, the second edition of his book "How to Make a Dynamo; a Practical Treatise for Amateurs" (Crosby Lockwood and Son). This is a very useful little book for mechanics or amateurs wishing to make their own dynamos, giving practical instructions and working drawings for the construction of a Gramme dynamo of 360 watts (45 volts and 8 amperes). The book has been enlarged to 100 pages, the price being now 2s. The castings for the various parts of the dynamo described can be obtained of the author at 7, Clarendon-street, Dover.

The Electric Exhibition at Birmingham.—On the application of Mr. T. C. Sharp, the Board of Trade have certified under the provisions of the Patents, Designs, and Trade Marks Act, 1883, that the Electric and Industrial Exhibition, to be opened at Bingley Hall in August, is to be regarded as an International Exhibition. The arrangements are progressing satisfactorily. The exhibition, which will remain open three months, will illustrate the application of machinery to most branches of trade, and will also include electrical novelties of exceptional interest. The applications for space are coming in fast, and there is promise of a most successful show.

Improved Telephone Transmitter.—Mr. S. B. Wilkins, the Edinburgh firemaster, has invented a new transmitter which promises to be a useful adjunct to the telephone. It is a bell-mouthed funnel of metal with an outer metal casing which carries the fixings for holding it in position on the telephone, so that the transmitter itself presents a free vibrating surface. It fixes readily to the ordinary mouthpiece of the telephone, and repeated tests have shown that it conveys spoken sounds with much greater distinctness than the ordinary mouthpiece. There are several transmitters on the same principle already in use, but it is claimed by Mr. Wilkins that his invention has a decided advantage in usefulness and cheapness.

Journal of the Institution.—We have received a copy of the last number of the *Journal* of the Institution of Electrical Engineers, containing the remainder of the discussion on Prof. Jamieson's paper on Insulation Resistance, Mr. Kennelly's paper on Imperfect Earths (with diagrams), and the paper by Prof. Forbes, Electric Lighting Stations in Europe. This latter is fully illustrated with plans and diagrams of the Rome and Milan districts, details of the switchboards and the Zipernowski dynamos, and also reproductions of the photographs shown at the meeting of the interior of the engine and dynamo-rooms at the various continental stations. The diagrams showing curves of comparative cost of maintenance are also given at the end of the paper.

Electro-Physiology.—Four prizes of 500f. each are offered by the Société Royale des Sciences Mèdicales et Naturelles de Bruxelles for the best four answers to the following questions: (1) Find the value, in electrical units, of the normal currents which exist in living tissues, such as the nerves, the muscles, and the glands. (2) Find what is the conductibility of the organic liquids (lymph, plasma, serum) of currents of low E.M.F., and, if possible, investigate the conductibility of the tissues. (3) Proceed with the investigations already made of electric endosmosis, and describe the possible applications of the theory of electric endosmosis to the phenomena of absorption and secretion of living organisms. (4) Find if the molecular structure of the protoplasm presents a variable complexity corresponding to the complexity of the functions. The answers are to be sent in by January 1, 1890, to the secretary of the above-mentioned society.

Utilising the Water Power of Canals.—In long stretches of canals there is little fall, but in short stretches there is often considerable water power available. An appropriation has recently been asked in New York for a million dollars to repair the canals of the States, which has been thought waste of money, and a writer in *Electric Power* suggests that a single-track railroad on one or both sides of the canal might be arranged, the power being obtained from water-power stations situated at the locks, a fall of 10ft. or 15ft. being easily obtainable, supplemented on long stretches by steam power. The suggestion seems to be of an ordinary railroad following to some extent the route of

Digitized by Google

canal and travelling at all speeds, and we might here suggest that if in any case there were available water power, an overhead telpher engine to draw ordinary canal boats might prove useful for slow traffic. The suggestion is commented upon in *Electric Power* as worthy of consideration, and the editor remarks "Niagara and the Erie Canal would be a strong team."

Beaumont's Variable Gearing.—In this journal for September, 1886, and again on June 29, 1888, we described and illustrated a variable gearing suitable for electric tramcars, the invention of Mr. W. Worby Beaumont, M.I.C.E. Mr. Beaumont has shown us a model of this gearing, which seems admirably adapted to the purpose for which it was designed. A wheel, with interior teeth, is revolved in a positive direction by a small toothed wheel geared to the motor shaft. A loose conical sleeve is arranged as a friction contact on the same shaft, and on screwing this into position by a handscrew the corresponding toothed wheel, otherwise itself stationaary, is revolved by means of a second friction wheel on a countershaft in the opposite direction to that of the driving-wheel. This, of course, alters the actual speed of rotation of the car-axle, and allows it to be driven at a slower speed. The model shown exhibits this action to be simple and practical, and we should imagine it will prove exceedingly useful in solving the problems of electric traction.

Electric Light for Flour Mills.—The extensive system of electric lighting recently established in the steam flour-mills of Messrs. Edward Marriage and Son, Colchester, was yesterday week formally inaugurated in the presence of the Mayor (Mr. E. J. Sanders) and other gentlemen interested in the development of various industries in the borough. The party assembled in the engine-room, where the "Crompton dynamo" has been fitted by Messrs. Christy, Son, and Norris, of Chelmsford, and the Mayoress having turned on the current, proceeded to inspect the mill. The mill is lighted by 120 16-c.p. incandescent lamps within, and outside is brilliant with the light afforded by four powerful lamps. Light refreshments were then partaken of, after which the Mayor and others congratulated Messrs. Marriage and Son on having kept pace in the march of improvement by fitting up their mill with such perfect machinery as they have done, and by employing the electric light. Messrs. Christy's firm appears to be making rapid headway in electrical work and make a speciality of lighting flour-mills. They have already fitted up 20 flour-mills with fittings, etc., for the light, and have orders for others in hand. We are glad to see such progress being made in this important field.

A Telephone Syndicate.—The *Northern Daily Telegraph* announces on authority that, after protracted negotiations, the directors of the three leading telephone companies in England have agreed, subject to the sanction of their respective shareholders, to amalgamate, and that it is their intention forthwith to connect, by a system of improved trunk lines, all the large towns of England and Scotland with each other. The total value of the three properties is close upon three millions sterling, and the area covered is London and all Great Britain up to Inverness, except South Wales and the West of England. It also includes the North of Ireland. In other words, the districts covered are those licensed by the Postmaster-General to the Metropolitan or United Company, the National Company, and the Lancashire and Cheshire Company. At present these companies have a gross revenue of £400,000 per annum. It will thus be seen what a vast corporation is coming into existence through the fusion of these important companies. The development of the system for the connection of all the great towns with trunk lines will be very costly, and alterations will have to be made in the annual rate now charged upon the existing lines. "The details of the telephone amalgamation," says the *Financial News*, "are not yet agreed, but we understand that the settlement will be based on recent market values, United Company shares being reckoned at £15, Nationals at £6, and Cheshires at £1. 11s. 6d."

An Engine - Dynamo - Accumulator Car. — A courageous attempt to take the bull by the horns and obviate all difficulties (rather, perhaps, we might say embrace them all) is made by the Patton Motor Company, of Chicago. This company equip street tramcars, and, not content with the ordinary methods of arrangement, propose to work their cars with everything aboard. That is to say, it is a storage battery system with the charging plant on the car. A small gas-engine will be set in front of the car connected to one or two horse-power dynamos. Under the seats on either side are the storage batteries, to be kept constantly charged by the dynamo and gas-engine. The motor will be underneath the car. The following are the advantages claimed. In the first place, the gas-engine and dynamo can be operated at a very slight expense, and the power can be obtained for much less than horses' cost. By having the batteries constantly recharged there is no need of two sets, which is the prevalent custom with other systems. Neither will they be so large and consequently so expensive as the other kinds. Their aggregate weight will be but about 500lb., it is claimed—scarcely a third of the other batteries. We hope they will get good-natured gas-engines, and have the movable connection to the gas mains perfectly airtight. Compressed gas of the nature familiar to politicians might be useful. We offer this as a kindly suggestion. It is stated that the cars will be running in a month or two. When this comes off, like John Gilpin, "may we be there to see."

Board of Trade Report on the Series Tramway. The Board of Trade have examined and reported upon the series tramway at Northfleet, and is very favourable to the undertaking. Mention is made of the mechanical arrangements generally being well carried out. Steps only must be taken to reduce the jolting at the junctions. Reference is made to the electric brake, no injurious effect to the brushes, it is stated, being caused thereby. The mechanical break must be adopted on any larger system, or for steeper gradients, to all wheels. For safety from unauthorised interference, it is recommended that the switch levers at the ends of the cars should be made movable, so that one set only is used, and these to be carried by the driver from one end to the other on reversing the journey, and removed on stopping. Upon the Board being assured of these conditions being complied with, they will consent to the running for public conveyance of passengers. Captain Cardew, R.E., in his report upon the electrical part of the plant, considers the arrangement a safe and suitable one for the purpose. He considers there is no possibility of inadvertently receiving a shock from the charged conductor, and that it would be very difficult to receive a shock even wilfully. The power is collected and applied in a simple and efficient manner, and he sees no

Digitized by Google

reason to apprehend any serious breakdowns or failures with a proper supervision of the generator and motor. He suggests continued attention to the regulation of the dynamo for constancy of current.

The Submarine Telegraph Company and the Government.—The following letter from "A Shareholder" appeared in the *Financial News* of April 8: "Sir,—It is only right that the fate of the Submarine Telegraph Company should be known, in order that others who have invested their money in similar undertakings should be warned. The right of a submarine telegraph company to land cables on the shores of these islands is contingent on the license of the Government to use the foreshore for that purpose. In the present instance, the Government, having resolved to undertake the business of the Submarine Telegraph Company themselves, have in the first place revoked the license to use the foreshore. Having thus rendered the cables useless to the company, the Government next proceed to purchase the cables at a price which it is not too strong to call confiscatory. The sum offered to the company, and which they are forced to accept, is less than a tenth of their original cost, and less than the amount of their net earnings during the last six months. This bankrupt dividend, for it is barely 1s. 4d. in the £, is a grievous loss to the shareholders. It may be said that the company should have provided against such an Act, but in the first place, it could never be anticipated that a Conservative Government would confiscate private proverty; and, secondly, the company have been lulled into security by the written promise of Lord John Manners, when Postmaster-General, to continue their license until 1898. This promise is now repudiated on the ground that it was conditional on the agreement of the French Government; but as the latter refused their consent at the instigation of the English Government, it is hardly a condition which can be taken advantage of by those who prevented its performance."

Lighting and Ventilation at Parliament.—In the House of Commons on the 8th inst., on the vote of £42,379 for the Houses of Parliament, the question of ventilation and lighting came up. Mr. Plunket said that since last session the electric light had been fixed in certain parts of the building, and during the Easter recess it would be carried into the lobby outside and into some other portions of the House. But the committee, he thought, would hardly approve of the Office of Works undertaking a very large extension in the present state of science with regard to the electric light. Sir W. Foster was of opinion that it was high time the House had the advantage of the best form of lighting that was already invented. An improved gas-burner consumed as much oxygen as five men required to breathe, and, therefore, gas ought to be superseded by the electric light, which did not consume oxygen. The atmosphere of the House had been so bad on one occasion that they were compelled to suspend the sitting. Of all places in the world, this House ought to have the atmosphere that was compatible with intellectual vigour. The air of the House was generally five or six degrees too high, and when they went into the lobbies they found the atmosphere still worse. Mr. Bradlaugh complained of the lighting of the dining-room used by members and their friends. Sir G. Campbell also complained of the temperature, and asked for some explanation of the fact that though the electric light had been introduced into the building, the gas bill had nevertheless increased. Mr. Conybeare advocated the more general adoption of the electric light in the precincts of the House. Mr. Plunket said, with regard to the electric lighting, the reason why it had not been carried out more completely was that just for the next few months it was not quite clear whether they would be able to light the whole of both Houses of Parliament more cheaply by making the electric light for themselves, or by obtaining it from some of the great supplying companies. The increased charge for gas, which an hon. member had spoken of, was caused by the autumn session entailing a larger consumption, in addition to which a greater number of rooms were lighted with gas.

Chelsea Central Station.—The work at the Chelsea central electric light station is being pushed forward rapidly to completion, and an unofficial start was made last night, light being supplied, by means of a temporary Brush engine used to charge the accumulators, to a shareholder's house in Sloane-street. We are precluded from giving any but general particulars of this interesting station for the present, as it is yet in course of construction; but a few details which we were able to gather on a recent visit to the station will put our readers in possession of the plan of the system. The Chelsea station is arranged on the system of distribution by accumulators, in sub-stations. The central generating station is situated in Draycott-place, Sloane-square. The first of the sub-stations, at Clabon-mews, Cadogan-square, is now practically finished, and regular distribution may be expected very shortly. The central station is fitted with Babcock and Wilcox boilers (two of which are now fitted) and Willans engines of 75 h.p. nominal, one of which is now fixed. These are to be coupled direct to Victoria dynamos. The latter are separately excited by a Brush plant with Raworth friction gear, and are arranged to supply current through underground mains (laid by Callender and Co.) to the sub-stations with a charging current of 75 amperes at a little over 500 volts. The sub-stations are very ingeniously arranged with automatic switches for charge, discharge, and regulation of pressure, the arrangements being carried out under the direction of Mr. King for the E.P.S. Co., who supply the accumulators and connections. Rocking switches are arranged, for charge in series and discharge in parallel of the batteries in two sets of four in parallel of 53 cells. The rocking switches are worked by a relay by means of the action of a small gasometer collecting gas from a single plate of the master cells. The raising of the gasometer shunts the main current and closes circuit of second rocking switch, when all goes on as before. The regulating apparatus is very ingenious, and secures a constant pressure in the mains, and equal discharge of current from the two sets of batteries. The apparatus seems at first a little complicated for general working, but no difficulty seems to be feared in actual working, and we shall be greatly interested in seeing the result in action of this courageous attempt to use sub-stations of storage batteries in distribution of electric light. As we go to press the secretary sends us a telegram as follows: "Chelsea Electricity Supply Company supplies current in Chelsea from to-night continuously."

Telegraph Charges to France.—Mr. Henniker Heaton, in a letter to the *Times* this week, points out that the proposed reduction of telegraph charges to France under Government control is insignificant. While the internal rate is halfpenny per word in England, we have been suffering from a rate of 2½d. per word to France, and are now threatened with a ten years' agreement at a reduction of

Digitized by Google

only halfpenny per word. The *Times* of the 6th inst. has a leader upon this subject, pointing out that the whole matter lies in a very small compass. A telegram from one end of the United Kingdom to the other costs a halfpenny a word. A telegram from one end of France to the other costs rather less—that is, it costs five centimes a word. But a telegram from Dover to Calais, or from any place in the United Kingdom to any place in France, is for the next 10 years to cost just four times as much—twopence a word in England, and 20 centimes in France. What is the cause and what the justification of this difference? This action (it goes on to remark) is as illogical as it is impolitic. The British Post Office makes no charge for submarine telegrams to Ireland, to the Channel Islands, or to any other outlying portions of the United Kingdom connected with the mainland by submarine cable. The charge for telegrams between France and Algeria is the sum of the internal charges in the two countries, no extra rate being levied for the cost of submarine transmission. The postal rate between England and France is the sum of the internal rates charged in each of the two countries, no extra charge being levied for conveyance across the Channel. Why should a departure be made in the case of telegraphic communication from this perfectly rational and intelligible principle. On April 8 Mr. Henniker Heaton recurs to the subject. The estimate, he points out, is "for the salaries and working expenses of the Post Office telegraph service in consequence of the new arrangements for working the submarine telegraph cables between England, Belgium, France, Germany, and Holland, £49,900." Mr. Henniker Heaton states that he was told the money was required immediately, or dreadful consequences would ensue, and five days afterwards he was supplied with a copy of the new arrangements with France, and two days afterwards with copies of the new arrangements with Germany, Holland, and Belgium. Then he learnt for the first time that Mr. Raikes, without consultation, had bound England down for ten years to submit to exorbitant telegraph charges. Mr. Heaton concludes by stating that the Chambers of Commerce in this country intend to take action in supporting the Paris Chamber in its protest against this state of affairs.

The Electric Light for Weybridge.—An adjourned public meeting was held at the National Schoolroom on Friday evening, to receive the report of the committee appointed to consider the best means of public lighting to be adopted for Weybridge. Dr. Sealy (chairman of the committee) read the committee's report, which stated that some step was imperatively required to place Weybridge more on a par with other residential parishes. Mr. T. Hawkins, who had acted as secretary to the committee, had gone carefully over the roads, and calculated that 85 lamps would be sufficient for the purpose, which estimate was afterwards adopted by the committee. The committee then considered the three different methods—gas, oil, and electric light. The Walton Gas Company offered to erect lamps for £2 per lamp complete, and supply the same with gas from October 1 to March 31, from sunset to midnight, at £1. 19s. 10d. per lamp. Eighty-five oil lamps, the committee found, of 35 c.p., with posts, etc., complete, could be erected, kept lighted and extinguished, for 26 weeks from dusk to midnight, all responsibility of breakage, etc., being borne by the contractor, for £295. A considerable desire existed in the neighbourhood for electric lighting, and this was no doubt called forth by the strong feeling of antipathy which existed towards the local gas company, as well as the desire of many to furnish their houses with the least injurious illuminant known. An offer had been received to erect the necessary plant and supply the lamps at 45s. per lamp, the light thus applied to be available during the summer as well as winter months, from dusk to 1.30 a.m. The committee unanimously recommended the last-mentioned method, being most in accord with the age in which they lived, as well as from every point of view most economical and desirable. In conclusion, they considered that the rate to be made should be 2d. in the £, which would produce £240 on the present rateable value. In reply to remarks by Mr. Thomas and Mr. Wardle, Dr. Sealy said there was no doubt, if the committee had been in a position to make a definite bargain, they could have got much more favourable terms. The Electric Lighting Company whose estimate they had received—Messrs. Laing, Wharton, and Down—was at present engaged in lighting Reading. He should suggest, however, that they should form a consumers' company amongst themselves. He thought the people of that neighbourhood had already suffered considerably at the hands of outside providers. Mr. Thomas said that Weybridge presented the special difficulty that they had the heath and common, two centres of population widely apart, and he thought the present was an unfortunate time to have selected for the adoption of lighting. He believed that the place of similar size had yet to be found where the light had been a success, and he thought the question should be postponed. Major Travers said he understood the company contemplated electric boats up and down the river, and that Weybridge would be the station for supplying the electricity, and that this enabled the offer to be reasonable. Dr. Sealy said it was true that the company thought of having stations on the Thames for supplying electricity, and that they proposed to have a depot for that purpose at Weybridge. The company's offer was irrespective of any house lighting whatever. If householders made use of the facilities it would reduce the cost of the public lighting. The chairman said he understood the offer of the company was that they would put up in Weybridge 100 lamps at their own cost, supply them with electric light all the year round up to 1.30 a.m., the charge to be 45s. per lamp per annum. He thought it an extraordinarily liberal offer, and one which they should accept. Mr. Maud thought that 100 lights spread all over Weybridge would be simply wasted; that the price mentioned was ridiculous, and that double the money could not possibly do it; and that if the firm carried it out it was not worth while accepting an offer which would ultimately result in a monopoly. Mr. T. Hawkins did not think that, whoever the lighting inspectors were, they would enter into a bad contract. He suggested that the lamps should be placed closer together in streets than in places where there was not much traffic. After a lengthy discussion nine inspectors were elected—Dr. Sealy, Major Travers, Messrs. G. Jarvis, T. Dix, Young, Nias, Chambers, T. Hawkins, and Wood—the whole of whom, in answer to the chairman, expressed themselves in favour of electric lighting. Another resolution was passed empowering the inspectors to make further enquiries, and limiting the sum to be expended by them to £230. The system proposed to be adopted by Messrs. Laing, Wharton, and Down is the incandescent lamps in series. It is understood that the lighting inspectors will also invite tenders from other firms.

THE RELATIVE ADVANTAGES OF SERIES AND PARALLEL WORKING ON ELECTRIC TRAMWAYS.

The enterprising spirit shown by the Series Traction Syndicate in starting the Northfleet line at their own cost and responsibility merely to publicly demonstrate the practical merits of their system cannot fail to be appreciated by all those who are interested in electric propulsion. At the same time this very interest should lead electricians to a more searching investigation into the claims put forward on behalf of this particular system of working. The argument by which the superiority of the series over the parallel system is sought to be demonstrated is exceedingly simple and, on the whole, plausible enough. We are told that the difference between the two is comparable to that existing in electric lighting. The Gulcher Company arrange their arc lamps in parallel between mains carrying some 60 or 65 volts, and if the number of lamps is considerable, and the area to be lighted extensive, the weight of copper in the mains becomes a very serious item, far greater than would be required were all the lamps arranged in series as is customary in the Brush or Thomson-Houston systems. In the same way, argue the supporters of the series system of tramway working, does this system effect a considerable economy in copper as compared with the parallel system. So plausible as this analogy appears, it has the fault of many other analogies to be misleading. The conditions in the two cases are by no means comparable. On the one hand, the pressure at which arc lamps are worked in parallel is very much smaller than that which can be conveniently applied to the working of motors, and, on the other hand, the pressure on the terminals of an arc light machine intended for a large number of lamps in series is far greater than any responsible engineer would care to employ in connection with the conductor of a tram line when this conductor must be placed into an underground channel, as is done in the system promoted by the Series Traction Syndicate. There is also another consideration which should be borne in mind. Electric tram lines for urban or suburban service are necessarily short, and in this country, at any rate, cannot be worked on any overhead system. The choice, there fore, lies between the conductor system with underground channel and storage cells. Where the traffic is light, the earning power of the line is too small to render the employment of an underground channel—the cost of which is almost independent of the size of the conductor as determined by the exigencies of the traffic—economical, and in this case storage cars offer the best solution of the problem. With a heavy traffic the underground conductor is, of course, more economical than either storage or steam cars, but only on short lines in towns. On long lines running across country no kind of electric car can compete against the train system worked by steam locomotives when the traffic is heavy, whilst for light traffic the overhead conductor system or storage cars may be more economical than steam, but the underground conductor system is obviously out of the question on account of its great first cost. Moreover, on lines across country this system offers no advantage as compared with the overhead system, and need therefore not be further considered in this connection. The question between parallel and series working of electric tram lines is thus narrowed down to a comparison of the two systems as applied to short lines on which the cars run at frequent intervals.

To avoid dealing in generalities, we propose to consider a definite case. Assume a line of four miles in length, with a five minutes' service of single cars. At a speed of from seven to eight miles an hour there will thus be about eight cars in motion, and the average power for each car may be roughly assumed as 6,000 watts, making a total of 48,000 watts, to be supplied by the generating station, irrespective of the losses in the conductor by leakage and resistance. In order not to complicate the calculations, we propose to neglect these losses for both systems, as far as the generating station is concerned, but putting the condition that they shall be equal for both. The generating station we assume to be established in the middle of the line. Considering, first, the parallel system, we must assume a safe and convenient pressure to work at. The pressure depends, to a great extent, on the possibility of insuring permanently a high insulation, but it is also limited by the difficulty of constructing small power compound or shunt motors for very high terminal pressures. Now, the power required from a tram motor varies, of course, continually with the state of the road, gradients and speed, and if the whole of the journey were performed at the highest speed of, say, eight miles an hour, the energy required may, on steep grades combined with sharp curves and a bad road, amount to 30 h.p., but on an average line the bulk of the work will be done between 5 h.p. and 8 h.p., and it is for the economical development of this amount of energy that the motor should be designed, although it must at the same time be capable of exerting a torque corresponding to 30 h.p. at full speed. Now, a motor designed for 8 h.p. is, after all, a small machine, more suitable for low than high voltage; and taking this into account, we think that most electrical engineers would not care to make such a machine for a pressure much exceeding 400 or 500 volts. Let us assume the lower of these figures as the standard pressure at which the parallel system is to be worked. Each car will then require a current of 15 amperes, and the total current flowing from the centre of the line, right and left, will be 60 amperes for each half. A five minutes' service could, of course, not be worked on a single line in both directions, and there will be a second line required, but this, as equally the case with the series system, we need not take into account. The insulation resistance of the conductor with a parallel system may be very high, as metallic parts of it need only be exposed at intervals, the rest of the conductor being capable of the highest possible insulation. We shall probably be within the mark if we assume the insulation resistance to earth of the underground conductor to be at least 2,000 ohms per mile. The resistance of a cable ¼ square inch in section may be taken as ·18 ohm and that of the return circuit through earth and rails as ·25 ohm per mile. Without going into any elaborate calculations, it may be assumed that the total loss of pressure due to resistance on each half of the line is equal to that which would take place if the current of 60 amperes were to flow a mile out and a mile home without being tapped on the way. This gives a total loss of 26 volts, or 6½ per cent. of the standard pressure. The total leakage resistance is 500 ohms, and the loss of current from leakage ·8 ampere. This is so trifling an amount, that it is practically without influence on the efficiency, and on that account might well be neglected. Yet, with respect of the maintenance of insulation, this leakage, small though it be, cannot be neglected, and must, indeed, form one of the items of comparison between the two systems under consideration. It may be stated as a general proposition that the amount of current allowed to leak to earth in any system of current transmission determines the rate at which the insulation will be destroyed, and to put the two systems upon an equal footing we must therefore arrange matters so that the leakage shall be the same in both. It may well be doubted whether a method of construction which requires the employment of "spring jacks" every 20 feet or so can give so high an insulation resistance as the cable used in parallel working; but we will give the series system the benefit of the doubt, and assume that the total insulation of the conductor to earth, spring jacks included, is also 2,000 ohms per mile. Under these circumstances it will be permissible to work the line at such a pressure that in no part of the conductor shall there be a potential greater than 400 volts either above or below that of the earth. We may therefore arrange to have a total difference of potential between the two ends of the line of 800 volts, or twice as much as in the series system. To get equal efficiency of conductor, we may also allow twice the loss, or 52 volts. Now, the total length of conductor is in this case eight miles, and the current passing along this whole length is 60 amperes. The resistance of these eight miles of conductor must therefore not exceed ·87, or, say, ·11 ohm per mile, and this requires a cable of about ·41 square inch section. It will thus be seen that the amount of copper required per mile of conductor is actually some 60 per cent. greater in the case of the series system, as compared with the parallel system, whilst the length is doubled.

Digitized by Google

The total weight of copper is therefore in the two systems, as 1 to 3·2. It might, perhaps, be objected that by placing the generating station into the middle of the line we have too much favoured the parallel system. Had we placed it at one end, the amount of copper required for this system would have been four times as great, whilst it would have made no difference to the series system. In this case the latter system would enable us to save some 20 per cent. of the copper, but against this saving must be put the cost of the spring jacks and other appliances which the complicated nature of the whole scheme render necessary. It is thus very doubtful whether even under the most favourable circumstances the series system has any real economic advantages over the far simpler parallel system. On the other hand, it has some very obvious technical disadvantages. In the first place, the large number of movable spring contacts inserted into the main conductor forms a very palpable danger of interruption of continuity because multiplying the number of points at which something may go wrong. In the next place, the maintenance must be a heavy item, and last, but not least, the starting power of each car is limited in the same way as it is limited in a steam-driven car. The current being constant, the maximum turning effort of the armature spindle is evidently determined by the strength of the field, and the limit of this is quickly reached. With a motor coupled across the mains, on the other hand, the turning effort may almost be indefinitely increased, because, with a constant field, it is proportional to the current flowing through the armature, which, as long as the car is at rest, is only limited by the very small resistance of the armature. The parallel arrangement affords, therefore, greater security against sticking on the line, and altogether a more absolute control of the cars.

DISTURBANCES ARISING FROM THE USE OF "EARTH" FOR ELECTRIC LIGHTING PURPOSES.*

BY W. H. PREECE, F.R.S., PAST PRESIDENT.

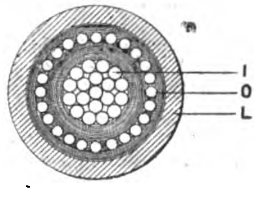
The magnetic field produced by a current flowing in a straight wire, and returning through the earth, extends to such distances that it is quite impossible to say where or when or how a telephone circuit in that field would be disturbed by any changes in that current. It is quite certain that if a single conductor between Deptford and London were subject to rapid alternations under a potential difference of 10,000 volts—the current returning by way of the earth—every telephone circuit in the metropolis would be disturbed, and probably rendered unworkable. The law determining the distance to which this influence extends was given by me in a paper read before the British Association at Manchester in 1887. It is given in the following equation:

$$C_2 = \frac{C_1 l}{d^2 r_2} \times M;$$

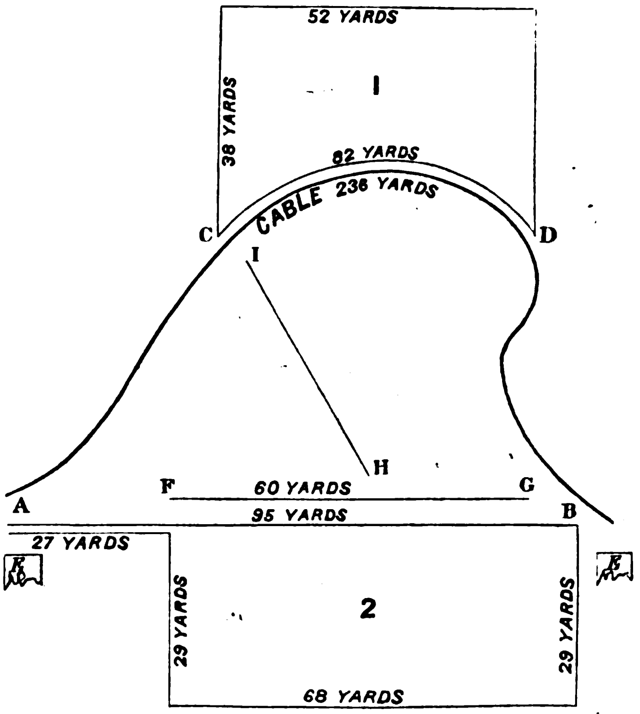
C_1 being the primary currents, C_2 the secondary currents, l the length of the primary, d the distance between the wires, r_2 the resistance of the secondary, M a constant dependent on the frequency of the primary currents and the rate at which they rise and fall.

It follows from this formula that currents of rapid frequency on a conductor 10 miles in length, carrying 100 amperes, might be evident at a distance of 19 miles. It becomes, therefore, important to decide to what extent disturbing influences can be eliminated. It is well known that if either the disturbing circuit or that disturbed be constructed of two wires so close to each other and so erected that the mean average distance between the disturber and the disturbed is the same, no inductive effects are evident, for the influence on one wire is entirely neutralised by the equal and opposite effect on the other. But if this mean average distance is not equal, or if the equality of the two currents be departed from, then a disturbance will arise which will depend on the difference between the two currents and their relative distances. Hence the most perfectly silent telephone circuit becomes noisy when leaks occur in the insulation, and hence it is that the earth plays such an important part in the efficiency of the system.

It was reported in the technical papers that the London Electric Supply Corporation contemplated laying a concentric conductor between Deptford and London, with the external copper conductor in contact with the earth. As it seemed to the Post Office authorities very doubtful whether such an arrangement would be free from disturbance, experiments were made to test the point. The experiments were made by me in an open space of two or three acres in extent. A concentric cable was constructed so that the outside and enveloping conductor could be insulated or not. The inner conductor was composed of a strand of 19 No. 15 B.W.G. (72 mils.) copper wires. The outer conductor completely surrounded the inner, and consisted of 24 No. 16 B.W.G. (65 mils.) copper wires. Each conductor weighed about 1,600lb. per mile, and gave a resistance of ·56 ohm. The outside sheath was of lead. The following is a full-size section of the cable:



The following diagram will explain the arrangement of the wires:



Two earth-plates were buried at the points A and B, and between them a No. 7 guttapercha wire was laid along the ground, telephones being inserted at each end. The electric light cable was laid between the same points by a circuitous route, as shown. At the points C and D two earth-rods were driven in, and another No. 7 guttapercha wire was laid outside the area enclosed by, and about a foot from, the cable.

Beyond each of the guttapercha wire, extension wires were carried to enable metallic loops to be made up, forming approximate squares (1 and 2 on diagram).

Experiment 1. A Wheatstone transmitter placed at B was connected to the inner conductor, I, of the cable, the lead sheath, L, being used as the return wire. Reversals at top speed (a frequency of 80 per second) were sent through the cable from an E.M.F. of 20 volts, the current strength being about 1·3 amperes. Loud disturbance was heard in the telephones at A and B when the transmitter was running.

Experiment 2.—Earth-bars were driven in at the points F and G, and connected by a wire and telephone. Currents were picked up by the telephone through this section, their effect being apparently quite as loud as between A and B.

Experiment 3.—The points H and I were similarly connected, and with a like result.

Experiment 4.—The points C and D were next connected by the wire attached to the earth-bars, a telephone being inserted at D. Disturbances almost as loud as on the circuit A B were heard.

Experiment 5.—The wire C D was disconnected from the earth-bars, and a metallic circuit forming an approximate square was made up (1 on diagram). The interference was still heard, but was only about half as loud when the earth was used at C D.

Experiment 6.—The insulated outer *conductor*, O, was substituted in place of the lead sheath as the return wire, and the disturbances in the loop C D ceased entirely.

Experiment 7.—The outer conductor, O, and the lead sheath, L, were coupled together, forming jointly a return wire in contact with the earth. The disturbance in the metallic square, 1,

* Paper read before the Institution of Electrical Engineers, Feb. 28.

Digitized by Google

reappeared, but was reduced in loudness to about half that in the fourth experiment.

Experiment 8.—The cable was next laid out straight from A to B, the telephone wire being parallel to it. When the lead sheath was used as the return wire, loud disturbance was heard in the telephones at A and B. When the lead sheath and outer conductor were jointly used as the return wire, the noise in the telephones was greatly reduced (to about one-fourth).

Experiment 9.—To prove that the result obtained in the last experiment was due to earth conduction, a metallic square (2 in diagram) was formed, and the disturbance in the telephones disappeared.

It follows from these experiments that the disturbance of the potential of the earth at A and B, and the establishment between these two points of a potential difference, cause currents to flow through the earth between A and B which destroy the equality between those in the inner and outer conductor of the concentric cable upon which equilibrium depends. It is, therefore, quite clear that the use of the external sheathing, as part of the conductor in contact with the earth is quite out of the question; whereas, if the enveloping conductor be insulated, it is quite innocent of disturbance, and would not intefere with neighbouring telephones.

The question has arisen as to whether the currents experimented with—viz., those produced by a Wheatstone transmitter, are of the same character as those produced by an alternating-current machine. The frequency in the two cases may be alike. Taking the frequency at 100, it will follow that each current, whether it be of the Wheatstone transmitter or of the alternating-current machine, will rise from zero to maximum and fall from maximum to zero in ·0025 second. The strength of current generally used in the Wheatstone transmitter is 50 milliamperes, while that of an alternating-current machine may amount to 100 amperes; and since most of the Wheatstone circuits in this country are long circuits, upon which the resistance and the capacity are considerable, it is quite evident that in actual practice the rate at which the current rises and falls is greater in the case of alternating-current machines that in the case of the Wheatstone transmitter. The fact that it is so is sufficiently proved in actual practice. Before the Grosvenor Gallery Company established their present metallic loop system, all the telephones around and about Bond-street were disturbed. In order, however, to settle the matter, I have carefully experimented with the currents produced by the alternate-current machines at West Brompton and at Eastbourne, and I find that it is quite impossible to detect any difference between the effects of Wheatstone transmitters and alternating-current dynamos.

These experiments, taken alone, are sufficiently definite to ender it decisive that the use of the earth in such instances cannot be allowed; but it may happen that in other systems of distribution where the currents are continuous and steady, such as the systems by which it is proposed to distribute by means of batteries, the earth, under exceptional circumstances, may be permitted.

THE TRANSMISSION OF POWER BY ELECTRICITY.*

BY FRANK J. SPRAGUE.

(*Continued from page 273*).

8. As a modification of the proceeding, especially where large powers, long distances, and necessarily high potentials are used, it is advisable to divide the generators and motors into a battery of machines of identically the same weight and character, the number of the machines being the ratio of the electrical efficiencies, the generators all to be driven from the same line of shafting, and the motors to drive on to a common line, and the current to pass through all the machines in series. This I consider the only sound method when dealing with large powers and high potentials and single units of generation and recovery, especially where automatic regulation is required. Its advantages are manifest. One of the greatest difficulties which we have in dynamo-electric construction in closed circuit machines, especially where using the drum system of winding, is the difficulty of securing perfect insulation when high potentials are used.

One thousand or 1,200 volts seem as high as it is now advisable to go in machines of this type, where currents of any magnitude are to be used. In the transmission of electricity, reliability is an essential, and a potential of 3,000 or 4,000 volts, distributed over three or four machines in series, is, despite the increased number of machines, far less liable to cause failure than where put into one machine of the aggregate size of the four; and in the event of the breaking down of one machine, the units may be so proportioned that by a corresponding change in the units at the other station, or a proper variation of the regulating shunt to the fields, it becomes quite possible to continue automatic operation. As an illustration of this distribution of machines, if wishing to use dynamos and motors of an electrical efficiency of about 95 per cent., a commercial efficiency each of about 90 per cent., and with about 60 per cent. as the total commercial efficiency of the circuit, I would, with a distance of about nine miles, use five series machines identical in construction, each wound for about 1,200 volts, three of which machines would be driven by a common line of shafting at the generating station, and two driving on to a common line of shafting at the receiving station. It will be noticed that both in the single and multiple unit series system, the E.M.F. and the current vary equally. I hope at an early date to be able to show this last system in practical operation.

The indirect methods of transmission, such as through a secondary battery of generators, motor generators, and secondary batteries, I will not here discuss.

I come now to the consideration of some new, interesting, and very practical formulæ for determining the elements of a single transmission of a given amount of power. Before entering upon its discussion, it is necessary to state why I differ somewhat from the methods which have hitherto been published.

Those who have followed with any particular interest the progress of the development of the transmission of power by electricity, must be more or less familiar with the early experiments of Deprez and the papers by Prof. Lodge and Mr. Gisbert Kapp. The experiments of Deprez have not had that practical result which had been hoped for them, and it seems to me as if an attempt had been made to go further than commercial demands warrant. We must avoid the consideration of the subject from a purely theoretical light. No system of transmitted energy can be made profitable unless the cost of the same at the far end, including not only the actual cost of production but the capitalised value of the possibility of accident due to the fact that the prime source of energy is not under immediate control, shall be less for the transmitted energy than the price that would have to be paid for its production there by water, steam, or some other agency. As attractive as the use of water-power appears as a prime source of energy, its uses are very limited, and every year will become more and more so; and unquestionably the great future of the transmission of power by electricity will depend upon the fact that in a large proportion of cases it will be cheaper to carry energy in the shape of electricity on a wire by the shortest cut between two points than to pack it up in the shape of wood or coal on the back of mule or behind a horse. I have no sympathy with the theoretically possible, but really impracticable consideration of the transmission of power, from Niagara to New York; for Niagara has a far greater value as a sublime spectacle than as a commercial factor in metropolitan affairs. I will then, in my estimates, confine myself to that which is practical and possible, and will consider the conditions under which power shall be so transmitted. Messrs. Lodge and Kapp have deduced some very interesting formulæ, but one of the conditions which was taken into account by them was that of leakage. In a purely theoretical study this is as it should be; but the transmission of power by electricity to meet the demands of actual life must above all things be reliable; and by this I mean, not merely certain to supply power at the end of the line, but to deliver a definite percentage under perfect regulation and a known cost. This cannot be done with the uncertain and variable element of an unknown but material leakage; for if this leakage exists, then it must be a variable quantity depending not only upon the condition of weather but likewise upon the continual variation which exists in the E.M.F. when the load is not constant. We meet, then, with the condition that in the successful installation of a plant for the transmission of power, we must be free from material leakage; that is, the leakage must be so small under all possible conditions of service as to never interfere with the efficiency and reliability of the transmission. Hence, in the formula which I in practice adopt to determine the elements of my work, I shall assume a line of practically perfect insulation. I am justified in this because the additional expense to secure this desirable result is more than compensated for by the reliability of the service. We can only accomplish this by the most careful line erection and choice of insulators. It can be materially aided by running the positive and negative leads each on an independent line of poles, and perfectly clear of all trees, and, of course, a well-covered wire can be used. When a double line of poles is used, it is advisable to wrap the lower ends with bare wire for a distance of about 6ft. above the ground, and to connect these bases together; or, if the poles are close together, a galvanised iron or copper wire should be taken around each pole at the distance given and joined together. This is to avoid the possibility of a serious shock in wet weather, which might be received by a person leaning against a wet pole if any accident should occur to the line insulators when very high potentials are used.

In the formulæ which are given, I shall make use of the term "couple efficiency." As long ago as the spring of 1888, Drs. John and Edward Hopkinson made tests of efficiency of double conversion with the Edison-Hopkinson and Manchester

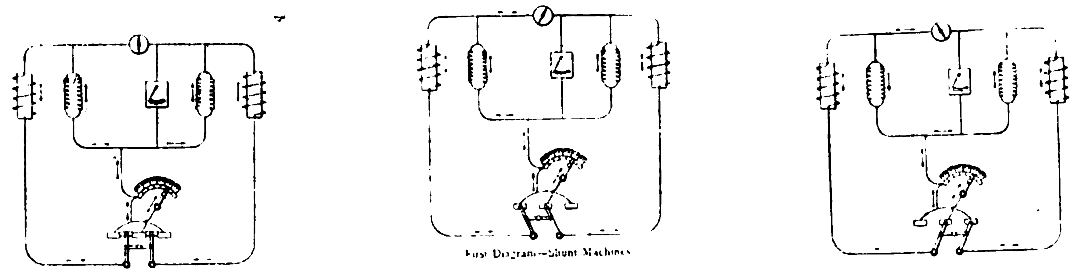
* A lecture delivered before the Franklin Institute, November 12, 1888.

Digitized by Google

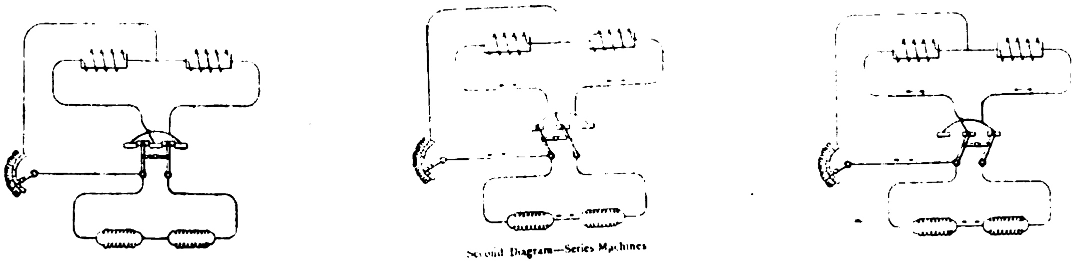
dynamos, the efficiency of the former rising at times to over 87 per cent., and of the latter to nearly 78 per cent. No others have made so thorough an analysis of the action of dynamo-electric machinery, and my own experience warrants me in assuming, for the purpose of this paper, a commercial efficiency of double conversion, where two machines are connected by a metallic circuit of no appreciable resistance, or what I have called the "couple efficiency," of not less than 80 per cent., which is only allowing about 90 per cent. commercial efficiency for the dynamos and motors. It will oftentimes rise higher than this, but I think it advisable in a specific formula to adopt a perfectly safe figure. This couple efficiency for either single, shunt, or series machines, or nests of machines, is easily determined with considerable accuracy and small expenditure of power. The method I prefer was one independently proposed, but similar to that first put into practice by Dr. John Hopkinson, that English scientific investigator to whom we all owe so much. It may be termed the variable differential method, and depends upon the use of an electro-mechanical couple. The first diagram illustrates the testing of two shunt-wound machines. Two such machines are belted to a common line of counter-shafting, having three pulleys, each being given its proper speed. dynamo. This reversal is not instantaneous, because it takes time for the field-magnets to charge and discharge. The ampere-meter will drop to zero, and will then rise again progressively.

This method of testing can be used for two purposes, one for testing the actual horse-power developed, and the couple efficiency, which can be done by measuring the current E.M.F. between the machines and the horse-power delivered to the shafting by the third motor, and for the other purpose of testing simply the heating capacity of the armature-coils with a given number of amperes. For this latter purpose it does not matter practically whether the machines are run at their normal speed and generate their normal E.M.F., or whether some lower E.M.F. is used. If a lower E.M.F. is present, it simply means that there must be a greater ratio of difference between the field-magnet strengths and a larger resistance used with the reversing switch.

When desiring to test the two series machines, the connections are somewhat different, and are illustrated in the second diagram; the machines, of course, being mechanically connected as in the first instance. We can similarly test a multiple unit series system; and in all these cases, by the introduction of an



First Diagram—Shunt Machines



Second Diagram—Series Machines

To the third pulley is connected a motor of about one-third the capacity of one of the machines to be tested, this motor being one of a perfectly well-known commercial efficiency, and provided with means for varying its speed; or, if desired, the power can be transmitted through a good dynamometer. The like terminals of the large motors are then connected together, an ampere-meter put into this circuit, and a potential galvanometer connected across the terminals. One terminal of each field is likewise connected to its proper line, and the other terminals of these fields are brought to the movable levers of a two-way circuit changing switch. One contact is carried to the main line, and between it and the other two is inserted a variable resistance, which in the middle position of the switch is short circuited. We have, then, the two large motors connected in an electro-mechanical couple, and to the same shafting is connected a third motor. The main dynamo being started, the switch set in the middle position, the motor is speeded up, which sets the countershafting in operation, and drives both the machines as dynamos, each exciting its own field. If the machines are symmetrical, no current whatsoever will pass over the branch connecting the two; they are simply in the position of two dynamos in parallel circuit with each other, with no external circuit, and no path over which the current can flow except that through their field-magnets; consequently, very little power, save that of friction, is taken. The switch being moved in one direction, the resistance is thrown into the field of one machine. The E.M.F. which it develops at this particular speed is now reduced; it becomes a motor, and current will flow over the connecting mains from the other machine, which is still a dynamo, which current is roughly expressed by the quotient of the difference of the E.M.F.'s of the two machines, divided by the resistance of the circuit. By varying the resistance in the fields this current can be made of any value up to the limit. We have here, then, one machine acting as a motor, and driving on to the counter-shafting with a certain number of horse-power, this counter-shafting driving the other machine as a dynamo with a certain greater amount of horse-power, this second machine furnishing the current which operates the first as a motor. The deficit, or loss of efficiency between the two machines and the friction, is supplied by the third. By reversing the switch the resistance is first cut out of one field, and then thrown into the field of the other machine. This machine now becomes a motor, and the other machine becomes a artificial resistance into line, we can produce all the phenomena of an actual long-distance transmission. This method of testing, where there can be an immediate variable and controllable reversibility of the dynamo and motor, and test of the efficiency of transmission under widely varying conditions, illustrates in one of the most beautiful ways the flexibility and utility of electric transmission.

Assuming, then, that we have no leakage, and that our dynamos and motors have a definite known efficiency, we will take up the consideration of a few formulæ.

Let l = distance between the generating and receiving stations in feet, plus the sag.
n = number of effective horse-power to be delivered on the motor shaft.
E = E.M.F. at the terminals of the motor.
v = number of volts fall of potential on the line.
E + v, or E′, being, of course, the E.M.F. at the beginning of the line or the terminals of the generator.
a = efficiency of the motor.
C M = circular mils of conductor.

An E.H.P. is 746 watts, watts being the product of current by E.M.F. Then for any horse-power, n, a motor efficiency of a and an E.M.F. of E at the motor terminals, we have the number of amperes equal to

$$\frac{746\, n}{E\, a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Allowing m ohms as the resistance per mil-foot of copper, the total line resistance would be

$$\frac{2\, m\, l}{C M}$$

for a complete metallic circuit. From the above we have for the drop or fall of potential on the line

$$v = \frac{746\, n}{E\, a} \times \frac{2\, m\, l}{C M} = \frac{1{,}492\, n\, m\, l}{E\, a\, C M}$$

or

$$C M = \frac{1{,}492\, n\, m\, l}{E\, v\, a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Substituting for m its approximate value, 10·5

$$C M = \frac{15{,}666\, n\, l}{E\, v\, a}.$$

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

BOARD OF TRADE ENQUIRY.

Our Platform.

One area—one company.

Pioneer overhead wires.

Arcs for streets and open spaces.

Incandescents for interiors.

Standardised voltage for distribution.

Uniformity of alternations.

No supply company to specify lamps or fittings.

Practical and scientific arrangement of mains and feeders, with due precautions for extension.

Standardised maximum variation of pressure.

The standard pressure to take into account requirements of power distribution.

Standard minimum of insulation.

TELEPHONIC AMALGAMATION.

Our interests do not tend much in the direction of telephony or telegraphy, but they are large branches of electrical engineering, although the engineering might be termed a delicate kind. Telephony in engineering matters stands to electric lighting somewhat as watchmaking in mechanical engineering does to locomotive building. At the present moment, however, if not from an engineering, at any rate from a commercial point of view, the action of the large telephone companies as shadowed forth in the daily papers is of extreme importance.

According to the most recent information, the principal telephone companies of the kingdom are to be amalgamated. This means, if it means anything, an absolute monopoly. The word does not frighten us, as in this case, among others, we firmly believe, and have constantly given expression to that belief, that telephony to be successful must be a monopoly. Our opinions have differed from those of many people, in that we thought and think that the monopoly ought to be in the hands of the Government and not in the hands of a company. The reasons for this opinion have been frankly and freely given. The nation acquired at a high price, some say at an exorbitant price, the telegraphic system of the country, and before they had really made the purchase pecuniarily successful came the invention of the telephone, and within a year or two proof positive of its success commercially. Telegraphy then had to fight against the younger introduction, and it also had to suffer from an agitation which resulted in the lowering of the tariff. Altogether, then, the telegraphs have, in the hands of the Government, had a hard time of it. We desire to exonerate the permanent officials from every suspicion of inability to realise the exact state of affairs. They are powerless when political strings pull the instrument. They cannot act, and can hardly advise, upon purely business lines. We assume

Digitized by Google

they are compelled to trim their operations to fit into the peculiarities of the situation.

Another point to be remembered is that telephony is held to be telegraphy under another name, and that the Government derive a revenue from licenses. The great question is, whether the revenue so obtained compensates for the loss of revenue due to competition? In our opinion it does not, and we contend that the difference against the Government will largely increase as telephony becomes generally adopted and carried on in a more business-like manner. No doubt the amalgamation of the companies will tend to introduce new blood into the management of the United, and, perhaps, tend to induce that corporation, or the new corporation, to work a little more in harmony with the wishes of its customers. Taking it for granted, then, that amalgamation means the installation of telephones throughout the length and breadth of the land—to be used as extensively as possible over as long distances as possible—one question the public will ask is, whether time and trouble can be saved by telephoning, instead of telegraphing. As regards the question of time, there may be doubts. Frequently with metropolitan messages it takes longer to "get through" than to send a boy. As regards the question of distance combined with time, we are inclined to think the telephone will ere long beat the telegraph. It has been assumed that telephony is impossible, under certain climatic conditions, over long distances. It has, however, been shown that the distances over which it can be worked are such as will make it a dangerous competitor to telegraphy; for a conversation of half a minute, a verbal statement, instead of a telegraphic one, will often facilitate business. A technical explanation can be given by telephone in a few minutes that could not be given by a telegram, and would take much longer and cost more if sent by letter, while time will be saved as against the latter, and, so far as accuracy is concerned, the telephone has the advantage, for the message can be repeated again and again till it is understood.

Every consideration, therefore, points to monopoly. There cannot be a number of companies roaming about over the country at their own sweet wills, erecting posts and wires, and obtaining compulsory powers. The value of the telephone is lessened by division. The more subscribers the greater the value, and it will not do, from a business point of view, for Jones to be on one exchange and Brown on another.

It is just possible that the promoters of the monopoly in the last days of the telephone patent may be thinking that the Government must sooner or later take over their work. We imagine they are not far wrong, and that this question has been considered in the proper quarters. If, however, the Government does not act at once before the trunk lines are erected, they will either have to pay another large bill to take over the telephone system, or leave the work entirely in the hands of private individuals. In the former case the direct money loss is easily seen, in the latter not so easily, as it comes gradually in the diminishing receipts from the telegraphs, or in a too great diminishing increase in such receipts. Whatever be the action or inaction of the Government, we shall advocate the extension of the telephones in every conceivable direction. The world is not to stand still because Governments fail to recognise the possibilities of new inventions, and whatever may be their ultimate intention the amalgamation of the telephone companies is an act which commends itself to every business mind, and we can only say, Go on and prosper.

The prosperity of anything that tends to enable men to transact business quicker, and with fewer liabilities to mistakes, must necessarily benefit the whole nation. Telephony is an invention of this character. Its development and utility under proper management is not understood, and cannot be understood, till it becomes a far commoner instrument than it is at present. Now a luxury in even business houses, it should rapidly become a necessity in every house. The exchanges will have to be opened day and night till they are got rid of altogether by some automatic arrangement to enable any subscriber to place himself in communication with any other subscriber should the latter's instrument be disengaged. It would not be very difficult to construct such an apparatus even now, but it would be far too costly to be considered commercially.

THE BENTLEY-KNIGHT TRAM.

We herewith illustrate the latest form of the Bentley-Knight motor truck and conduit. Fig. 1 shows an end view of the motor truck, and Fig. 2 a sectional view. The conduits for a double track are laid in the space between up and down tracks, examples of which are to be seen in Boston and New York. The advantages claimed are that every part is accessible, repairable, and replaceable from the street surface, and the width of the slot can be regulated at will, without interference with the pavement. The excavation required to lay conduits, as shown, is said to be much less than is usual. The space between the tracks—that is, where the conduits are placed—is the least-used portion of the street, the cleanest and the best drained. What with the combined energies of this company, of the Daft Company, of the Sprague, and other pioneers of electrical street railways, America has taken first place in this kind of work. One of the lines engineered by the Bentley-Knight Company shows how flexible their work is. The line is about four miles in length. For one-fourth of this distance the conductors are contained in a sub-surface conduit. For the remainder of the way the conductors are elevated above the roadway, bracketed off from poles erected along the kerb line on one side of the street. The conduit branches from double to single track, and at the terminus there is a conduit cross-over switch from down to up track. At different points along the conduit section, the conduit cuts through

five other street railway tracks belonging to other companies. This shows the kind of difficulties that can be overcome by the conduit system. We shall be glad when we can chronicle such work in England. Elsewhere we have critically discussed the series *versus* the parallel systems, not from any desire to place the one above the other, but with a view of arriving at the truth as to which is the better.

PECULIARITIES OBSERVED IN TESTING MATERIALS.*

BY W. CLELAND, B.SC.

The materials in common use, when under the action of stress, pass through two states of existence—the elastic state and the plastic state. Under the former we have Hooke's law (*ut tensio sic vis*) expressing the proportionality of stress and strain, but no law has yet been found to show such a connection while under the latter state. It is of this state that I wish to speak about particularly. As mentioned in the heading to the paper, I intend bringing before the members of the society some peculiarities observed when testing materials of construction, leaving it for those of a more philosophic turn of mind than I am to put their own construction on the points noted.

I purpose, first of all, to give a description of the instruments (I should rather say machines) used, then to note the external points observed during a test, next to examine what can be revealed by means of the curve connecting stress and strain, and, finally, pay more attention to that part of the curve beyond the elastic limit.

The testing machine represented in Fig. 1 has not been chosen as being the best type, but as the one with which I am most intimate. It is the single lever form, and is known as the Wicksteed machine. In the sketch (which is diagrammatic), *a* represents the test piece under test held by the two jaws, *b*, one of which is connected to the piston of the hydraulic cylinder, *d*, and the other to the lever, whose arms are c_1 and c_2. This rests on the standard, *e*, and in order to balance the pressure on the piston, which is transmitted through the test piece to the lever, a monkey weight or poise, *m*, can be run along the lever. In the machine under question *m* weighs one ton; ratio of the arms of the lever is as 50:1. The pressure on the ram is got by means of a screw pump, while the total load transmitted is 100 tons. The stress is ascertained by a vernier attached to the travelling weight and a scale fixed on the beam. When once we have read 50 tons; if we want to go beyond this, the weight, *m*, is run back to zero and a load of one ton hung at the end of the lever. In testing, all that is necessary is to keep the beam floating free of the stops, and this can be very conveniently done by regulating the supply of water and the rate of application of the load. In fact, when testing it is quite possible to keep the beam midway between the stops until near the end of the test.

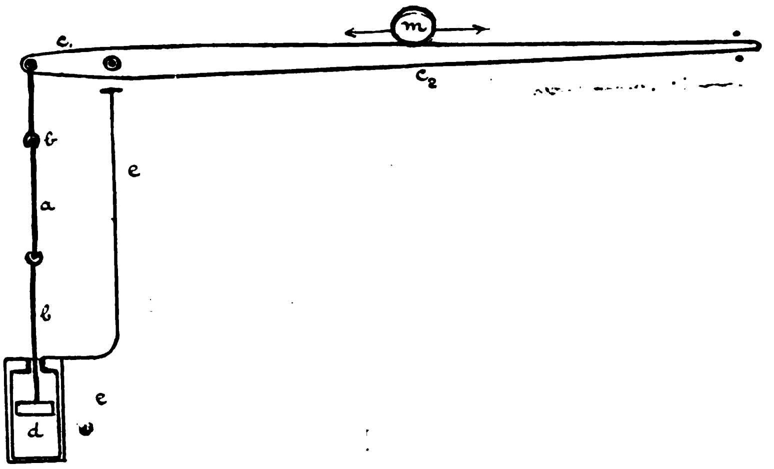

FIG. 1.—Wicksteed's Testing Machine.

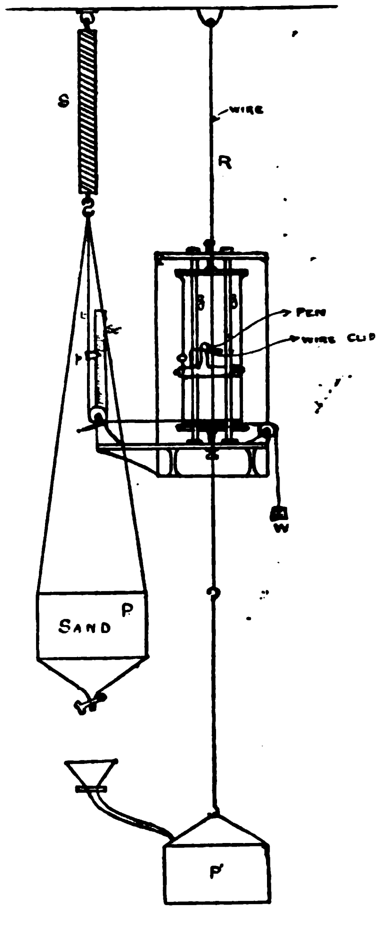

FIG. 2.—Prof. Barr's Wire-Testing Apparatus.

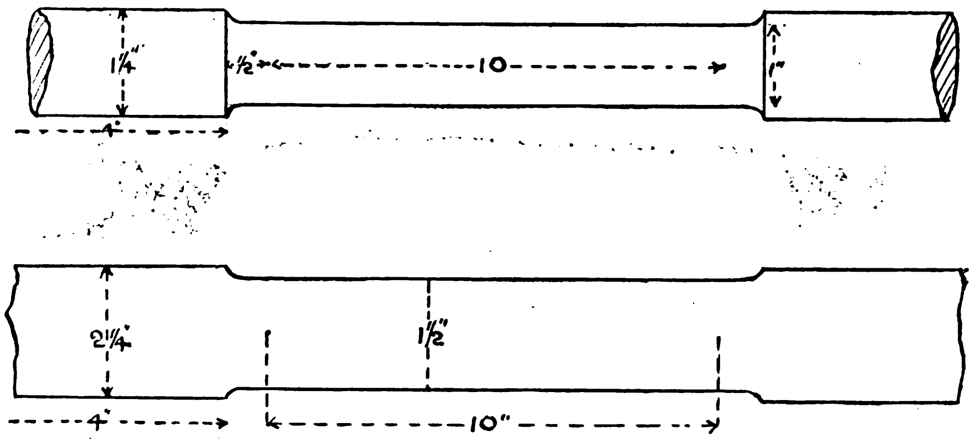
FIG III



Form and Dimensions of Round and Flat Test Specimens.

Some of the curves shown in this paper have been diagrammed by a wire-testing machine, designed by Prof. Barr. It is sketched in Fig. 2, and has the following action. S is a spring of known strength, from which is suspended a pan, P, with a stop-valve at the bottom containing fine sand. D is a drum, with very fine centres, so that it runs almost frictionless, attached to the spring by means of the thread, *t*. The thread, with the weight, *w*, at its end, is wound round the drum in the opposite direction to the thread, *t*, thus offering a uniform resistance to the motion of the drum. To the wire, R, a pan, P^1, is hung for the reception of the sand coming from P. For recording the strain of the wire, a pen is attached to it, the holder for which slides vertically by means of the guide-bars, *g g*.

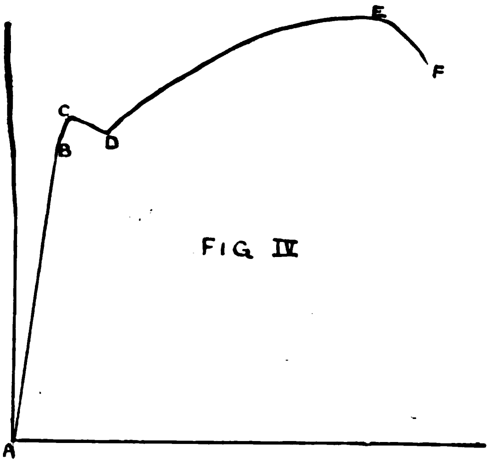
To indicate the rate of application of the load a pointer, *p*, is attached to the thread, *t*, and the reading taken on the scale (Sc.), which is graduated in inches.

When making a test, first fill the pan, P, with sand, then set the pointer, *p*, to zero on the scale. By lifting the penholder, trace out a vertical line on the paper fixed on

* Paper read before the Physical Society, Glasgow.

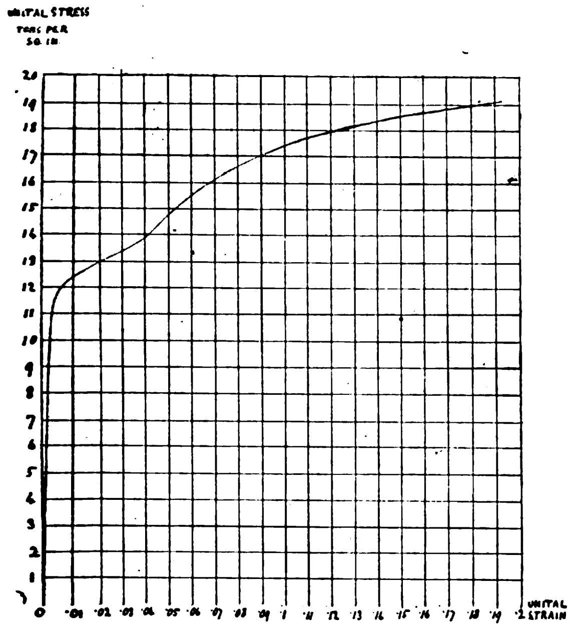
Digitized by Google

the drum. Turn the latter round a distance corresponding to the weight of the pan P^1, the hook, and the penholder. Then after clipping the penholder on to the wire, open the valve at the bottom of P, and allow the test to proceed.

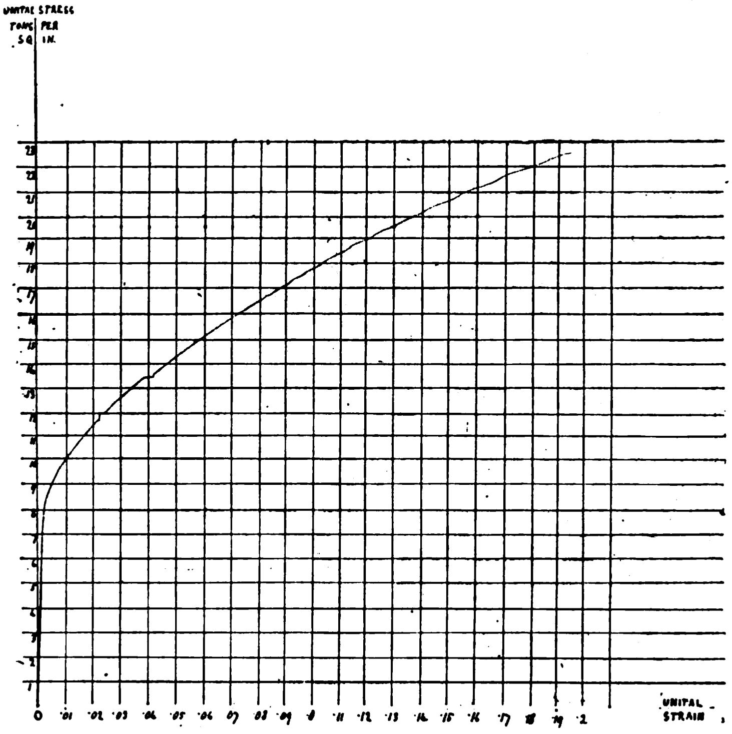


Fi 4.—Exag erated Form of th Stress rain Curve.

When finished, produce the straight part of the curve back to meet the straight line previously drawn. The scale for the curve is got from the known strength of the use of the metal from which the specimens have been taken. In describing the pecularities observed, it is necessary to select some material, as each material has its own characteristic, and mild steel having the greatest variety, I have chosen it. We will take a round specimen, and first mark two gauge points, 10in. apart. Divide this distance into half-inch lengths by circles drawn round the specimen. During the test, if we keep constantly measuring the 10in. length, we find that when a certain load has been reached, elongation occurs very rapidly, and that the elongation, which before this point was reached was almost nil, is now comparatively large. The stretching seems to be uniform along its length, as far as can be observed by means of the parallel lines. Now, however, the lever is seen to rest on the bottom stop, and the specimen begins to contract in diameter at some point. The load is run back, but it finally gives way at this place. (A portion of a test piece containing the local contraction is sent with the paper for the members to inspect.) If we apply the hand to this place while the specimen is under test, we experience an exhibition of part of the work done under the form of heat, and another part shows itself under the form of magnetism. After breaking, the specimen seems to be strongly magnetic. One peculiarity which shows itself very strongly in mild steel more so than in iron, is the coned form of the fracture. This is always seen in a more or less imperfect form in specimens of mild steel, and as far as I have observed it is



Autographic Test of Iron Wire. (Annealed.) Nov. 26, 1888. Length tested = 24·38in. Diam. = ·0178in. Area = ·00025 sq. in. Speed = 1lb. per 48 secs.



Autographic Test of Brass Wire. Nov. 17, 1888. Length tested = 28·25in. Diam. = ·017in. Area = ·000227 sq. in.

spring; for example, if the spring elongates ½in. for a load of 1lb., then ½in. on the diagram will correspond to a stress of 1lb. on the wire. It has been objected to this machine, that for practical purposes, or for purposes of comparison, that it is of very little use, as material in the form of wire is altogether different from the comparatively unstrained condition of the same material as used for purposes of construction. Of that there is no doubt, but still, from a coil of wire two pieces can be got much more similar in nature than when taken from a rod of iron. Besides, for the purpose of experimenting it is most convenient. Loads can be applied as quick or as slow as we please. Again, we are always sure that the results obtained under different conditions belong to different treatment and not to the specimens themselves, as specimens taken from different parts of a coil of wire are as near as possible practically identical.

Having now described the instruments used, we will turn to the specimens themselves.

The sketch in Fig. 3 shows the usual form and dimensions adopted, but the dimensions vary according to the the top part which has the projecting cone. Everyone knows that the fracture of a piece of iron is of more or less of a fibrous nature, while that of steel is crystalline in form. That can be seen from the specimen sent; but if examined closely, certain pittings are observed, which seem to be due to hard pieces in the steel. Now, this occurs very often, I may say without fail, in the specimens we have tested at the Yorkshire College, and to me they seem due to the mode of testing, for if another piece be taken from the same bar of steel and tested under different conditions, the pittings diminish in number.

Such are the features observed when steel is tested under ordinary conditions; and before proceeding to examine the external features when tested under different conditions, I will quote a passage from a paper on "The Flow of Solids," by M. H. Tresca (*Proceedings* Inst. of Mechanical Engineers for 1878):

"For all bodies two distinct periods are recognised: the period of perfect elasticity, which corresponds to variations of length proportional to the forces applied; and the period of imperfect elasticity, during which, on the

Digitized by Google

contrary, the changes of dimension increase more rapidly than the forces producing them. If the second phase of deformation be alone considered, it is easily understood that it tends towards an ultimate condition in which a given force, sufficiently great, would continue to produce deformation, so to say, without limit—as may be observed in the process of drawing lead wire. This particular condition, in which the deformation is indefinitely augmented under the operation of a sufficiently great force, constitutes, in fact, the geometrical definition of a third period, which has been designated by the author as the period of fluidity. The period of fluidity is more extended for plastic substances; it is more restricted, and will even disappear altogether, for some vitreous or brittle substances. But it is perfectly developed and extremely extended in the case of clays and of the most malleable metals."

(To be continued.)

LITERATURE.

Electro-Deposition: A Practical Treatise on the Electrolysis of Gold, Silver, Copper, Nickel, and other Metals and Alloys, etc. By ALEXANDER WATT. With numerous illustrations. Third Edition, revised, corrected, and enlarged. Crosby Lockwood and Son. 1889.

This book is probably the most practical book on the special subject it treats in the English or any other language. Mr. Watt has made a life-long study of his subject, and his investigations have almost always been undertaken with the direct object of introducing something better into practice. What the practical world of electrolysis owes to his writings is best known to those engaged in the profession, but the mere fact that this large work has reached a third edition shows how much it is appreciated. In this edition we note that considerable attention has been paid to Cowles' process to obtain aluminium alloy. No book is perfect, and usually the index is a weak point. Here we have an unusually good index, but still imperfect. Wishing to test both index and the book, we looked for "Molloy," but his process for obtaining gold from its ores is not given. We hardly expected it would be, for the work is not directly metallurgical; but "gold" is indexed under p. 514, where we failed to find it. This is perhaps only said as a foil to what might be termed unstinted praise, for generally the greatest care has been taken to arrive at correctness, and if fault should be found it would be for the redundance rather than insufficiency of matter. Technical books are of two kinds: one purely scientific, appealing to the pure scientist; the other giving information to the unlearned in pure science. This book belongs to the latter class, and appeals more directly to the man who has to do the work than to the man who wants to find a chemical formula for certain reactions. It is unnecessary to say more of a book in its third edition. It has stood the test, and has not been found wanting.

BOARD OF TRADE ENQUIRY.

Major Marindin, C.M.G.R.E., on behalf of the Board of Trade, on Thursday week resumed the enquiry at the Westminster Town Hall for the purpose of hearing, on the part of a number of electric light corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

Continuation of the case of the London Electric Supply Corporation, Limited, which was represented by Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham, instructed by Messrs. Deacon, Gibson, and Metcalfe.

Lord Crawford and Balcarres was recalled and cross-examined by the City Remembrancer.

Witness thought that the lighting of the City area would result in a good profit to the company. They proposed to enter the City at Cannon-street Hotel and Ludgate-hill Station. As he had said the previous day, he could not allocate any part of their capital for the City lighting. He did not ask a way-leave for their mains in the City for nothing, or without incurring the responsibilities incidental to such way-leave. If they did not accept those responsibilities, they were liable to be turned out of the area altogether. He thought that for street lighting the arc lights were preferable. As to the number of public lamps that would be required in the City, so far as he could gather from the specification issued by the City of London Commissioners, he found that there were three districts, and in the first of these there were 388 gas burners, in the second 526, and 633 in the third, making a total of 1,547. If they took a third of those gaslight burners, they would see that about 500 electric arc lights would supply the same light. He could not tell what number they contemplated putting up. He was prepared to light the City on as good terms as were offered to anyone else.

The **Remembrancer:** But are you prepared to light the City on as good terms as any other company?

The **Witness** declined to answer the question. What he meant by saying that he dealt very tenderly with the Chelsea Company was that the Chelsea Company had already got certain statutory powers, and it would be unfair for another company to come in and ask for less powers. Therefore they consented to the proposal of Chelsea that they should put themselves in a more unfavourable position with regard to that parish than other places.

Cross-examined by Mr. A. C. Cripps, who represented the Metropolitan Company, the **Witness** said that it was his conviction that it was more economical to supply electricity from one large station that from a number of small generating stations as was proposed by the Metropolitan Company, one of the conveniences being the facility and cheapness of getting their coal supply.

Mr. Cripps (representing the Metropolitan Company): Are you aware that, as regards two of the stations proposed by the Metropolitan Company, they are riverside stations with the same conveniences that you have at Deptford?

Witness said he was aware that there was one there. He believed there was one at Waterloo Bridge—Greenmore Wharf was the name of the other. His experience was that in these central stations navigation coal had to be used, and the expense would be 20 per cent. more than that of the coal used at Deptford. He was aware that modern appliances abated the smoke nuisance. They had tried these appliances, but had failed with them, owing to the noise that they caused. They could not get rid of the noise though they might get rid of the smoke. He had never had the pleasure of being at the generating station at Whitehall, and he did not know the conditions under which the work was carried on there; but it was a small station capable of supplying only 5,000 lights simultaneously. (A voice: "13,000 lights.") It was also situated in the middle of property belonging to one person, and the only neighbour it had was a large hotel—the Hotel Métropole—on the opposite side of the way.

Mr. Cripps: Putting aside the question of the cost of coal, then, it comes to a question whether you can work without causing any noise or not?

Witness said it was to a great extent. He believed, too, that the saving that resulted from economy in supervision was considerable.

Mr. Shiress Will, Q.C., M.P., on behalf of the House-to-House Supply Company, asked how much capital had been spent on the works at Deptford.

The **Witness** replied that he could not tell. The company proposed to duplicate the machinery, so that they might be prepared to cope with any accident which might happen to one portion of it. The pressure at which it was proposed to distribute the current would be 2,400 volts. They would distribute it from as many centres as they had local authority to do so—possibly 18 centres, which was the number of authorities they had to deal with. The cost of laying the mains would be about 6d. a yard.

In further reply to Mr. Cripps, he said that it would be as easy to supply the Marylebone district as a place only 100 yards away from their distributing stations.

Mr. Loyd asked how the company proposed to allocate the light?

The **Witness** replied that they would give 10,000 lights to each district for which they sought powers, excluding the City proper, to which they were prepared to give 30,000 lights. They proposed to give an all-night supply and to be able to give a day supply if required. There was no more difficulty in satisfactorily supplying the current from Deptford than there was in supplying gas from Beckton. The leakage would certainly be larger in gas than in electricity. A distributing station differed from a generating one in this—that it required no moving machinery, there was no fuel burned, and consequently there was neither smoke nor vibration. By their system they did not store electricity. They would be in no worse position than a storage company supposing that a strike were to continue for more than 24 hours. At the Grosvenor Gallery they supplied at the present time about 33,000 lights. The Electric Lighting Act of 1882 had led to considerable delay in the development of electric lighting. They had made agreements with the various railway companies for wayleaves to bring their mains into London at different points.

Mr. S.Z. de Ferranti, chief electrical engineer to the London Electric Supply Corporation, was next examined by Mr. J. C. Graham. He deposed that the corporation commenced work at Deptford about a year ago by making considerable excavations over a space of about 200ft. square. They had put up buildings and chimneys sufficient for 24,000 h.p. They had now got the machinery for 6,000 h.p. complete, the remaining 18,000 h.p. being in course of erection. They had two sets of engines of 1,500 h.p. each, capable of generating electricity to supply 25,000 lamps. In addition to that they would have two engines of 5,000 h.p., so that their available h.p. would be 13,000, capable of generating 250,000 lights. He saw nothing remarkable in having such large engines, considering the size of those employed now in steamships. They did not intend to work their machinery up to more than 150,000 lamps, leaving a margin of 100,000. They were to lay six mains from Deptford to London, with concentric conductors—two to London Bridge, two to Cannon-street, two to Blackfriars, and two to Charing Cross. They would be carried on cast-iron brackets which were provided with indiarubber or porcelain supports, so as to ensure proper insulation. The mains were so arranged that they could be switched on to any of the engines at Deptford, so that in the

Digitized by Google

event of one of them breaking down it could be easily replaced. The distributing stations would be supplied from those mains, and in order that there might be a total failure of light in London there must be a breakdown of all their mains and engines at the same time—a contingency highly improbable. The tension in the mains was to be 10,000 volts, and would be converted at their distributing stations into 2,400 volts by means of transformers. The supply from each distributing station would be a duplicate one, so that both sources of supply would have to fail before London was plunged into darkness. It was precisely the same system as was working at the Grosvenor Gallery with so much success, each distributing station being to all intents and purposes a small Grosvenor Gallery. A transformer served precisely the same purpose as a regulator for reducing the pressure of gas, steam, or water. The loss of pressure from the Deptford mains would be about ½ per cent. per mile of the energy sent, or 1 per cent. on the five miles. When the mains were in full working order with a pressure of 10,000 volts, nobody could be hurt by taking hold of them. They were perfectly insulated. The pressure at which they were to work was no element of public danger any more than the system adopted at the Grosvenor Gallery, where they had experienced no trouble whatever. There were great advantages in having their central station at Deptford—such as cheapness of land, and coal, and, besides, they would have sufficient storage space. They would have capacity for storing 30,000 or 40,000 tons of coal. Then they had all the advantages that arose from the concentration of their work, not to speak of the abundant supply of water which they would get by being on the banks of the Thames. At the Grosvenor Gallery they were very much troubled with fog. It came on so suddenly that it put an immense strain on the station. The fog did not envelop all the districts of London at one time, so that by having a large area to light they would not necessarily have to put the whole of their pressure on at once—that was to say, the City might be using its lamps when the West End did not require to do so. He had no personal experience of the electric light in America beyond what he read and heard, from which he gathered that the transformer system gave much satisfaction there. There were over 120 central stations in America upon that system.

Cross-examined by Mr. Moulton, Q.C. (representing the Chelsea Electric Supply Company), the **Witness** said that there were some towns in France where the system was adopted. Nancy had 10,000 lights running at the present time. They had also the transformer system at Milan and Vienna. At the Grosvenor Gallery they had no electrical difficulties which had not been thoroughly over come, and what difficulties they had had arose from want of space and their plant. The plant was not originally designed with a view to provide for extensions in their supply, so that they had been effected with very great difficulty. There was not, however, a trouble which they had experienced at the Grosvenor Gallery which would have to be dealt with at Deptford. He did not think their only advantage was in being on the river side. Other people had access to it as well. As to the matter of coal, he did not think that their machinery would require less than 200 tons a day to supply 100,000 lights. He could not tell the inspector what a system that employed storage would require. He was practically acquainted with only small storage installations. There had been no such large dynamo used before as they proposed to use at Deptford. It would be 20 times the size of that in use at the Grosvenor Gallery, and the pressure at which the current would pass along the mains would be four times as great as that hitherto used in London for ordinary purposes. Some of their mains were laid underground at the Grosvenor Gallery station. They were worked at a pressure of 2,400 volts. It did not appear to him that insulation was more easily attained by overhead wires. Underground mains, he thought, were adapted for a general supply.

The enquiry was then adjourned.

The enquiry was resumed on Friday morning.

Mr. S. Z. de Ferranti was recalled and cross-examined by Mr. Moulton. He said that his experience of electric lighting had not lasted for many years. From everything he knew the system which they proposed to adopt with regard to the jointing of their underground mains would not break down. The mains could be either curved or on expansion joints. Which was the more desirable system, time alone could tell. The Nancy system had different lamps, and had been supplied for a year and a half. His dynamos were started very nearly a year ago there. A current in the main, which would destroy the insulation, would certainly affect the main externally. His experience of a load of that kind of high tension, however, was that it did not affect it immediately. Safety fuses were set at a very small amount above the carrying capacity of the mains. His experience was that a partial leak could not occur to a concentric main. At Nancy they had had no fault in the insulation. What he meant by concentric mains was a stranded core, then insulation then wire stranded round that again. They proposed to connect with earth at the Deptford end, but to insulate along the line in order not to disturb telephone and telegraph wires. If any other point got to earth, there would be no leakage affecting the lighting system, but there would be a leakage to effect a disturbance. It would disturb the telephones. There would be practically no shock felt by touching those huge conductors. They had tested for the purposes of the underground railway to see whether the concentric mains supplying the current, and put to earth at one end, would give a shock, and they could not feel it. In transformers the pressure varied inappreciably, they found. The efficiency within the transformer itself varied, but he said it was not of considerable importance as regarded the supply from the station. They proposed to have a transformer in each house. He had heard that that practice was not allowed in America. He had heard that the regulations in America admitted a pressure of only 1,000 volts. He did not know that the insurance companies, who refused to allow transformers in a house, regarded them as a source o danger. At present they were laying their mains along the railway and their experience with concentric mains showed that there was no external effect when they were short-circuited. They had short-circuited them with 20,000 volts, and worked with two 50-horse transformers in series with a lead-covered table, which showed it more easily. Their present plant would be equivalent to probably a quarter million lights. In case of a breakdown the interval of time required to switch one dynamo on for another was inappreciable. The darkness occasioned thereby would be too short to be appreciated by the eye.

Cross-examined by Mr. Shiress Will, the **Witness** said that their whole system of lighting would depend on the current coming from Deptford.

Cross-examined by Mr. Lyttleton (on behalf of the Metropolitan Supply Company), **Witness** said that the chief difficulties they had experienced at the Grosvenor Gallery station arose from the peculiar nature of their position. He did not know what the rentals of their distributing stations would amount to. These would be placed in convenient situations—presumably in accessible cellars. Their object was to distribute a large force of electricity over an extensive area economically. He felt sure it could not be supplied so cheaply by any other process.

Cross-examined by Mr. Russell Griffiths on behalf of the City Remembrancer, **Witness** said he knew that the City street lamps burned 4,000 hours in the course of the year. In addition to the applications which Lord Crawford said he had received for 70,000 lights, there would be the street lighting. It was not necessary to have a transformer in each house. It might be so arranged that 20 or 30 houses could be lighted with one transformer. So also the street lamps could be arranged in series of 20 lamps.

In further reply to Mr. Loyd, he added that preparations were now being made for bringing the mains into London across the river at London Bridge, Cannon-street, Blackfriars Bridge, and Charing Cross, agreements having been made with the various railway companies for way-leave. He considered that the street lighting of the City was the reverse of important to the company. They would be better without it. It would be commercially better for them to confine themselves to private lighting. There would be no transformers in the streets, but in the cellars which they rented. As to the testing-boxes, they would be placed at the corners of the streets like Post Office letter-boxes. The number of these that would be required to a mile of mains would depend very much on the nature of the streets. He could not give an approximate figure.

Cross-examined by Mr. Wilkins, representing the Vestry of St. James', Westminster, **Witness** admitted that if the consumers in that parish depended exclusively on the company for their electric supply, they would be deprived altogether of it if the station at Deptford broke down. There would be a saving of about 10s. per ton in coal by having their station at Deptford; how much in wages he could not say. He did not anticipate that there would be a great deal of wear and tear of the mains by running them at a pressure of 10,000 volts. The whole of the current would be generated at Deptford according to present arrangements. They sought no monopoly of the area which they wished to supply.

In further reply to Mr. Graham, he said that no danger could arise to the public from the short-circuiting of the inner and outer conductor. Their object was simply to supply electricity, and allow consumers to use it for whatever purpose they chose. He did not regard their scheme in the nature of an experimental departure. Their large dynamos were divided in such a way as to make them form a number of small dynamos for all practical purposes, and they would be much less strained than their present ones. He thought it was a much greater step to go from an 800 h.p. engine to one of 1,500 h.p. than it was to go from the latter to 5,000 h.p. after what they had experienced. Everything had been carefully considered. The effect of putting more or less work on to their transformers would be a slight fall in efficiency, not so much, however, in putting it on as in taking it off. They were designed to do an average amount of work. He had never heard of any serious accident from transformers placed in private houses. They had not so much objection to their having many testing-boxes as to their having to pay for the ground on which they were placed. His calculation as to the quantity of coal that would be consumed was based on actual experience at the Grosvenor Gallery. He thought there was no difficulty in ensuring the safety of their mains from being crushed by vehicular traffic.

Mr. George Richard Strachan, surveyor to the Vestry of Chelsea, was next examined by Mr. Loyd, and deposed that the Vestry was in favour of admitting competing companies to their parish, believing, as he himself did, in the beneficial results from a public point of view of competition, and they had granted their consent to the London Electric Supply Corporation to go there.

Dr. John Ambrose Fleming, examined by Mr. Graham said he had visited the United States in 1885, and studied electric lighting there, especially the incandescent systems established by Edison. At that time the transformer system had not come much to the front, and there were no central stations on a large scale. Since then there had been an enormous extension of the transformer system both in the United States and in Europe. All reserve power was provided for by means of spare engines, boilers, and dynamos. There were upwards of 200 lighting stations in the United States dependent on these means of reserve force. There were, in a sense difficulties in insulating every current of high or low tension, but they were not insuperable. The higher the degree of E.M.F. the greater would be the precaution required to be taken, but there was no impossibility in doing it. His recollection of the City of New York was that about 100,000 lights would be used per square mile, including private houses, shops, and warehouses. The efficiency of a transformer would be affected if it were too heavily loaded. The scheme of the London Electric Supply Corporation was

Digitized by Google

merely experimental in the sense that the Forth Bridge was—in point of size. In his opinion there was a greater economy of electrical energy by the use of transformers than there was by the use of secondary batteries.

Cross-examined by Mr. Russell Griffiths, the **Witness** said that he had seen an engine of about 600 h.p. employed, but the ones generally used in America were from 300 to 400 h.p. The direct system was chiefly adopted in America. The mains were laid in 20ft. lengths, there being 20 miles of them laid in New York. They were all connected with one central station. There was no sensible leakage from the joints. The electrical pressure in them was 100 to 200 volts, never in excess of the latter figure. He had tried experiments with a pressure of 10,000 volts on flexible and rigid conductors, but not on any system of mains. The loss of energy on the Edison system was very small.

Examined by Mr. Graham, **Witness** said that the question of leakage was merely one of care in the insulation. Joints were not necessarily a source of weakness if properly made.

Mr. Musgrave Heaphy, technical adviser to the Phœnix Fire Office, examined by Mr. Loyd, said that he had examined installations on the transformer system. He had heard of the proposal of the London Electric Supply Corporation to increase the voltage in their mains to 10,000, reducing it by means of transformers to 2,400 in the distributing mains. He had considered the question from an insurance point of view, and he did not think there would be the slightest danger if the work was performed according to the Phœnix Fire Insurance Office rules.

Cross-examined by Dr. Hunter, M.P., **Witness** said that the English mode of insurance was not conducted on the American principle. He had heard that American fire offices would not insure premises unless the transformers were situated outside the building which had to be lighted. But he spoke as a practical man, and could say that where an installation had been properly put up, he had never known a single instance of fire. There was no appreciable risk in having the transformers inside houses if the Phœnix Office rules were observed. It did not matter from an insurance point of view whether the voltage was 10,000 or 20,000.

Cross-examined by Mr. Russell Griffiths, **Witness** said he had seen the majority of installations in London under the transformer system. He thought it would be advisable to build in every house using the light a fire-proof chamber for the transformer. In the majority of instances it was already done. He had made this year an enormous number of inspections for insurance in London where installations on the high tension system were put up, and he had not known of an instance of fire occurring from them. The risk was very slight.

Major Charles B. Waller, manager of the London Electric Supply Corporation, examined by Mr. Graham, said that the company had received 82 applications for light from the City, 21 from the Strand district, 10 from St. Pancras, 40 from Marylebone, 40 from St. James's, 15 from Westminster, and 75 from various other parishes, making 277 in all. In addition to these, they had many hundreds of applications in the form of letters which were not registered. In the majority of cases the applicants were waiting to receive the current from the Deptford station when it was in proper order. Those applicants would want, in round figures, 50,000 lamps of 10 c.p. If they had a current for 100,000 lamps they could place the whole number in the city at once with private consumers, excluding the public lighting.

Cross-examined by Mr. Hunter, he said that they had a very large demand for lighting in the neighbourhood of Cadogan-square, not as the result of the energy of canvassers, but due to the requirements of the public. They had never had any system of canvassing. He had been manager of the corporation 18 months, and during that time he had no complaints about the failure of the supply of the light. They had not been always able to give as good a supply as they had wished. There had been very large extensions of their business during his management—principally by overhead wires.

In answer to Mr. Lyttleton, he added that they proposed to close the Grosvenor Gallery station as a generating centre as soon as the Deptford one was open.

Cross-examined by Mr. Russell Griffiths, **Witness** said that it was generally assumed for all practical purposes that London took one gas-light per head of the population. That was what the corporation which he represented went upon in estimating what strength of electric current would be required for lighting a given area. Eventually they would be prepared to supply the City with 300,000 lamps if they were wanted. They would endeavour to keep pace with the demand.

Cross-examined by Mr. Wilkins, he said that the company, where they were now supplying light in 99 cases out of 100 required a pole on a roof of a house for the purpose of carrying the cable and the right of user for the general system of their cables. They had had some customers who discontinued their system of lighting. A few were no doubt lured away by perhaps the better terms of other companies, while others preferred to go back to gas for the sake of economy. In some cases they discontinued to use it because they did not pay their bills. They had about a fourth of their customers on meters supplied by the firm of Messrs. Ferranti and Co.

Mr. Ferranti, recalled and cross-examined by Mr. Wilkins, said that the cost of bringing the electric current from Deptford, compared with the cost of the plant at Deptford, would be in the proportion of 7 to 100.

In reply to Mr. Cripps, he said he thought it would be desirable to have two companies supplying the same district, in which case he would suggest that both of them should lay their mains together so as not to break up the streets twice. The space required for electrical mains was not large. It would not be always an advantage to have their mains in close proximity to the houses. He did not think that anybody would lay a trunk main along the Strand, but merely the mains that were intended to supply the neighbourhood. They would be in a position to lay all the mains within three months of the granting of the provisional order.]

COMPANIES' MEETINGS.

ELECTRICAL POWER STORAGE COMPANY, LIMITED.

The eighth ordinary meeting of this Company was held on Wednesday, the 10th inst., at Winchester House, E.C., Sir Daniel Cooper, Bart., G.C.M.G. (chairman of the Company) presiding.

Mr. Holland Dell (secretary) having read the notice convening the meeting,

The **Chairman** said: I now propose to offer some remarks and explanations upon the report, and the figures in the statement of accounts where they seem to call for observation. During the past year there has been a gratifying increase of business. This increase is mainly made up of a great number of small orders for storage batteries, which are employed for the variety of purposes detailed at length in the Directors' report. By far the larger portion of the gross profit of £13,273. 15s. 3d. has been earned in the manufacturing branch of the business, as the firms and companies on the Continent who have agreed to manufacture Electrical Power Storage batteries, under royalty, have taken a longer time to complete their arrangements than was anticipated. There is an increase of £165. 5s. 9d. in the item of rates and taxes, owing to the payment of income-tax. We have not done so much advertising lately, so there is a diminution of £293. 6s. 8d. in that account. The shares allotted last year to the Managing Director had been charged against the reserve at par value. The Company has taken out what we believe to be valuable patents in the United Kingdom, and in several continental countries for improvements in details of arrangement in the Electric Power Storage accumulator, and also for distributing apparatus in connection therewith, and much time and thought has been given by Mr. Frank King, our chief engineer, and our technical staff to perfecting what is commonly known as the Electrical Power Storage system of distribution by storage batteries. On the other hand, law costs and patent fees account is less by £194. 2s. 3d., because we have had no professional fees to pay, and are for the present free from litigation. The amount allowed for doubtful debts has proved more than ample for the purpose, and there is a balance over, which we consider sufficient for this year. There has been, as mentioned in the report, some additional outlay, owing to the increase of business, on the plant and buildings at Millwall works, and further outlay will have to be made this year. The amount under the heading of "sundry creditors" is larger, but against this is the increase in sundry debtors' account, while the cash balance at the bankers is £3,000 more than it was last year. In the report is given a selection from a long list of new electric light installations in which Electric Power Storage batteries are used. Reference is also made to various scientific and technical institutions which have adopted accumulators, and I do not think I need here enumerate them. You will have noticed that Electric Power Storage batteries are now used for all kinds of purposes—train lighting, ship and yacht lighting, omnibus and carriage lighting, and for power in tramcars, electric launches, and again for surgical purposes. In short, their use is becoming general, as you will have gathered from the paragraphs which have appeared in many newspapers during the past year, and you may take it that, though the name of the Electric Power Storage Company has not always appeared, yet, in 99 cases out of 100, the batteries were the Electric Power Storage type. Among the latest interesting applications of batteries, I would mention the printing at the office of the *East Anglian Times*, at Ipswich, by power supplied by Electric Power Storage batteries, which are placed at the central lighting station of Messrs. Laurence, Paris and Scott, Limited, in that town, a description of which was sent to the shareholders with the report. I must now dwell for a moment on the subject of central station lighting, the importance of which to this Company cannot be overstated. The Company has applied for provisional orders for Paddington, St. Martin's, and the Strand districts, and an enquiry is now being carried on, under the instructions of the Board of Trade, upon questions which relate to the whole of the applications for provisional orders in the metropolis. I shall refrain from making any observations thereon, as the matter is still *sub judice*. I will now pass to the Chelsea Electricity Supply Company, which is supplying light in the parish of Chelsea. You may not be aware that this is the first company which has supplied electric light in London under the statutory powers of a provisional order. It has acquired these powers by Act of Parliament, Vic. 50, cap. 18. The Electric Power Storage Company, in conjunction with the Anglo-American Brush Company and the Callender Bitumen and Telegraph Company, took up the Chelsea Company last July, and contracted to furnish the necessary plant, and they have now carried it through to its present stage; and I feel confident that the combined efforts of the three companies, each in its own special line, will result in a model central station. The system of distribution is that of the Electrical Power Storage Company, by which the current is supplied from the main station to storage batteries placed in convenient sub-stations throughout the district to be supplied. We believe this system to be the best for such populous districts as Chelsea, and that the public will give the preference (when once they become acquainted with its essential features) to the only system in which a reservoir of light, in case of accident from any cause whatever, is provided. Our managing director, Mr. Courtenay, is a director of the Chelsea Company, having joined the board at our request. You will, perhaps, have read the pamphlet issued by the Electrical Accumulator Company of New York. I need only remark that judgment has now been given against the Julien Company for infringing the Faure patent, and therefore that company will be put under injunction. The trial of this suit has taken more than twelve months, and the investigation has been one of a most searching and exhaustive character. The shrewd advisers of the American company consider, as they state in the document referred to, that they had already got the control of the accumulator business in the States from their other patents, even without

Digitized by Google

the Faure patent, and now they have this basic patent also declared valid, their position should be doubly assured. I beg to move the adoption of the report and accounts, and ask Mr. Sellon to second the resolution.

Mr. John Scudamore Sellon: Gentlemen, in seconding the resolution, I have little to add upon general points to the remarks of the Chairman, or to the matters dealt with in the report. It would, of course, have been gratifying, and doubtless for many reasons acceptable to all of us, and certainly more pleasant for the Directors, if we could have arrived at the conclusion to recommend a dividend. One large shareholder remarked to me, after the report had been published, that, if we had declared one, our shares would immediately have doubled in market value. This may be the case, although in view of what is before us, I see no reason why our shares should not quadruple in value, without our troubling ourselves about a dividend at present. The Directors are bound to consider the exigencies of the business they direct, and are not justified in diverting what they consider necessary for the protection of the internal interests of an undertaking simply in order to affect the external value of the shares. It has been a labour of years to build up this business, to overcome violent antagonism, and to establish the secondary battery upon a firm basis as an indispensable and reliable factor in electric lighting. This having been at last accomplished, and the first great start given, would it not be unjustifiable to do anything which might cripple us for a moment in grappling with the great extension of work which is before us? Instead of diminishing the resources at our command, we could with considerable profit employ further capital. In fact, every £1,000 in a growing business of this kind is of value, and I may say that, realising this, your Directors have not for, I think, fully two years taken out any of their well-earned fees. On former occasions I have somewhat exhaustively dealt with most of the technical questions in connection with this undertaking, and I have pointed out the wide and extensive range of work which lies before us. I need not, therefore, now detain you with any further remarks on such points, but, perhaps, you would permit me to say a few words on your position as owners of patents. The Chairman alluded to the recent important decision given in the courts of the United States in favour of the Faure patent, after one of the hardest patent fights on record. With the exception of one decision, sustainng one of the Thomson-Houston patents for an arc light regulation device, this is the only electrical apparatus patent pertaining to lighting or motor business, the litigation on which, in the courts of the United States, has terminated favourably for the patentee. The Faure patent is one of those which, as you know, is held by the Electrical Accumulator Company of America, a powerful corporation formed to work our patent rights in the United States, and in which we hold, I am glad to say, a very considerable interest The importance of the decision will be obvious to you when I explain that this patent entirely controls the use of active material supplied to the plates, and I assure you that no efficient, practical secondary battery can by any known means be made without such application. It is a fundamental and essential point of construction. I ought, perhaps, at the same time, to mention that the Swan patent, for simple perforation plates, came before the same court and was not upheld; but the decision did not arise from any invalidity of the invention itself but upon a matter of form, proof not having been put forward, I presume from some oversight, as to the earlier date of the English patent compared with that taken out in the United States. If considered necessary, this can doubtless be put right, and this priority—it is incontestably capable of proof—can be established; but, in any case, the matter is of no great importance. Though the patent is an important one in itself, the manufacture of plates, as carried on by all the infringers, comes within the claims, not only of the Faure patent, which has been upheld, but of several other of the Electrical Power Storage group of patents which are held by the Accumulator Company. Of course, neither here, nor in other countries where we hold patents, is the Swan patent in any way affected by this temporary decision of the United States court. I would take this opportunity of explaining to you that you possess in the Electric Power Storage group of patents some 40, all more or less important, fully covering each and every point and detail of our business, and, so far as is within my knowledge, not one single outside patent exists which would be of use to us in our manufacture, or which would, as the Americans call it, be worth a red cent. to us. Several of the patents are, as in the case of the Faure, covering or controlling patents, in the sense that no economical and efficient secondary battery can be constructed without infringing them. Every perfect plate now made embodies the principles of no less than four of these patents in its manufacture, and in the completed cell the details come into play. Then, as several of these patents are of recent date comparatively with our basic patents, you have the great advantage of prolongation of the term of your practical monopoly of manufacturing storage batteries, because, naturally, the most perfect battery is the one which will always command the market. You will, therefore, feel justified in considering your position in this important and indispensable branch of the electrical industry to be not only unique, but unassailable. I would only further remark that as time passes and experience is gained the more absolute is the confirmation of the views put forward by myself and a few others some years ago, but doubted and criticised at the time by many electricians, even of eminence, that it is to the employment of the secondary battery that we must look for the attainment of the most reliable, safe economical, and generally acceptable system of electric lighting; and I confidently anticipate that one of the results of the important investigation now being carried on under the commission of the Board of Trade sitting at Westminster Town Hall—which is literally absorbing the interest of the electrical world of England—will be to enable, not only electricians, but the general public, more vividly to realise the solid and paramount advantages of the storage system which this Company advocates and controls.

Mr. E. C. Schomberg expressed his dissatisfaction at no dividend being declared, but the Directors proposing to carry forward a balance of net profit to the amount of £8,372, he urged that a portion of this ought to be divided among the shareholders.

Mr. J. W. Barclay, M.P., commended the policy of the Directors, thinking it would be a great misfortune to starve the Company. He congratulated the Board on the position the Company had attained, which was due to the Directors' pluck and energy, and thought it gave promise of very substantial and, he might say, brilliant results in the future. He believed the commission now sitting would give a great impetus to electric lighting, that extensive orders from foreign countries would bring in a large revenue, and that the value of this Company's interest in the American company would greatly develop.

Mr. John Irving Courtenay (managing director) answered some questions put, and said he hoped that in the current year the Directors would lay before the shareholders a scheme for raising further capital, taking into account the debentures which would fall due in May of next year. He stated that the holding of this Company was nominally of the par value, £140,000, and he believed that company had the control of the business over the whole of America.

The motion was carried unanimously.

Mr. Barclay proposed the re-election of Sir Daniel Cooper and Mr. Courtenay as directors, and the motion was seconded by **Surgeon-Major De Tatham,** and carried unanimously.

On the motion of **Mr. Grindle,** seconded by **Mr. Schomberg,** Messrs. Deloitte, Dever, Griffiths, and Co. were re-elected auditors, and the meeting concluded with a vote of thanks to the Chairman, which was moved by **Mr. Barclay,** and seconded by **Mr. Schomberg.**

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY, LIMITED.

The half yearly meeting of this Company was held on Wednesday, at Winchester House, Sir John Pender presiding.

The **Chairman,** in moving the adoption of the report and accounts, said the gross receipts for the half-year amounted to £238,854, against £232,660 for the corresponding period of 1887, showing an increase of £6,194. The amount would have been considerably greater but for the loss of subsidy, £2,700, and probably £5 000 of additional traffic, resulting from the unfortunate interruption of the Australian section referred to at the last meeting; in addition to which there had been during the half-year the heavy loss of £6,947 on exchange in consequence of the increased depreciation of the silver currency. The working expenses amounted to £71,519 against £69,570, being an increase of £1,949, mainly due to the cost of the repairs of cables having been heavier than in 1887. Comparing the figures for the whole year with those of 1887, the results were as follows: Gross receipts in 1888 £478,730, against £451,861, showing an increase of £26,919, or over 1 per cent. on the share capital; working expenses, £140,911, against £145,811, showing a decrease of £4,900. An interim dividend of 1¼ per cent. having been paid for the past half-year, it was now proposed to pay another dividend of like amount, making, with the interim dividend for the first half-year, a total of 5 per cent. for the year. It was also proposed to distribute a bonus of 3s. per share, making a total of 6½ per cent. for the year. The balance of £66,101 had been carried forward to the reserve fund, which now stood at £690,454; in addition to which £15,401 had been charged against revenue for the cost of completing the renewal of the cable from Singapore to Saigon, and £4,292 for the rebuilding of the staff quarters at Cape St. James. The net result of the past year's working was that the reserve fund had been increased by £70,359, the cost of renewals of the Singapore-Saigon and Java-Australian cables, and of the rebuilding of the staff quarters at St. James, amounting together to £38,879, had been paid out of the revenue, and 6½ per cent. distributed to the shareholders. Since the close of the year, the laying of the new cable between Java and Western Australia, to which reference was made at the last meeting, had been successfully completed, the cost of that extension, the object of which was to strengthen their system and minimise risk of interruption, being £130,000. In concluding, Sir John remarked that everything was going on satisfactorily, that only one of the Company's cables was at that moment interrupted, and that in consequence of their having duplicate, and in some cases triplicate, cables, when a break occurred there was no cause for alarm.

The motion (which included the declaration of a dividend) having been seconded by **Viscount Monck,** was adopted.

The retiring Directors were re-elected, and a vote of thanks was given to the Board.

MONTE VIDEAN AND BRAZILIAN TELEGRAPH COMPANY.

An ordinary general meeting of this Company was held at the offices, 2, Tokenhouse-buildings, E.C., on Tuesday last, under the presidency of the Chairman of the Company (Mr. Charles Cameron, M.P.).

The **Chairman,** having moved that the Directors' report and statement of accounts should be approved and adopted, said the report this year was more favourable than had been the case on any previous occasion, owing to the improvement in the revenue of the Western Brazilian Company. The Monte Videan revenue depended upon the earnings of this company. Mr. Ogle's report stated that he had examined the books of the Company and found them correct, but that the Western and Brazilian had objected to an inspection of their accounts, and, therefore, he had not been enabled to verify their takings. This difficulty arose under an original agreement, under which the Platino Company had a right of inspection of the Western Brazilian, and, consequently, their auditor had access to the accounts, and saw that they were paid a proper percentage of the receipts. For

Digitized by Google

many years their Company had access to the books of the Western Brazilian, but after a while they objected, and they found they had no powers to enforce an inspection.

Lieut.-Colonel Macaulay seconded the adoption of the report, which was carried *nem. con.*

A dividend of 3s. 6d. per share on the preference shares of the Company, absorbing £1,454. 19s., was declared.

The Auditor of the Company was re-elected.

NEW COMPANIES REGISTERED.

Northampton Electric Light and Power Company, Limited.—Registered by Deacon and Co., 4, St. Mary-axe, E.C., with a capital of £20,000 in shares of £1 each. The object is to carry on a general electric motor and lighting business. The first subscribers are:

Manfield, F. H. Thornton, and R. E. Crompton. The remuneration of Directors shall be determined in general meeting.

CITY NOTES.

Great Northern Telegraph Company.—The receipts for the month of March amounted to £21,000.

Brazilian Submarine Telegraph Company.—The receipts for the week ending March 29 amounted to £5,351.

Eastern Telegraph Company.—The receipts for March were £55,987, as against £54,376 for the same period of 1888, or an increase of £1,611.

Eastern Extension Telegraph Company.—This Company's traffic receipts for the month of March were £42,896, as against £39,670 for the same period of 1883.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Telegraph Company, were £3,993.

Glasgow.—We are notified that Mr. Rankin Kennedy has ceased to manage the Woodside Electric Works. The proprietorship remains the same as formerly, and the business will now be carried on under the name of the Woodside Electric Company.

West India and Panama Telegraph Company, Limited.—At the approaching meeting of this Company, the Directors will recommend a dividend of 12s. per share, on account of arrears of dividend on the first preference shares, and an addition of £1,000 to reserve, carrying forward £1,154.

Indo-European Telegraph Company, Limited.—After transferring £10,000 to the reserve fund, the Directors of the Indo-European Telegraph Company, Limited, recommend a balance dividend of 17s. 6d. per share, together with a bonus of £1 per share, making a total distribution of 10 per cent. for the year ended December, 1888.

PROVISIONAL PATENTS, 1889.

April 1.

5515. **Improvements in telegraph instruments.** Arthur William Cox and Walker and Co., London and South-Western Railway Station, Winchester.

5563. **Improvements in electric batteries.** Henry Harris Lake, 45, Southampton-buildings, London. (Lacombe and Co., France.)

April 2.

5612. **Improvements relating to the distribution of electric currents, and to apparatus therefor.** Henry Harris Lake, 45, Southampton-buildings, London. (Edwin Wilbur Rice, junr., United States.) (Complete specification.)

5615. **Improvements in the generation of electricity on railway trains.** Illius Augustus Timmis, 2, Great George-street, Westminster.

5621. **Improvements in and relating to electric induction-coils or transformers.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.) (Complete specification.)

5640. **Improvements in or relating to electric railway signals.** Alfred Julius Boult, 323, High Holborn, Middlesex. (William H. Waddell, United States.) (Complete specification.)

5656. **A novel arrangement for conducting an electric current through the nose.** Herrman Welcker, 11, Wellington-street, Strand, London.

April 3.

5676. **Improvements in electric bells.** David Reid and James Kean, 154, St. Vincent-street, Glasgow.

5738. **Improvements in and connected with insulators for electric light and other wires.** Arthur Wellington Fitch, 4, South-street, Finsbury, London. (Richard Oliver Gardner Drummond, South Africa.)

5730. **An improved combined ampere and volt meter.** Samuel Joy and William Henry Joy, 37, Chancery-lane, London.

April 4.

5768. **Improvements in wooden casings for electrical conductors.** Walker George de Forgés Garland, 191, Fleet-street, London.

5774. **Electric lamps.** Robert Percy Sellon and Arnold John Spiller, 112, Belvedere-road, Lambeth.

April 5.

5816. **Improvements in electrical accumulator or secondary batteries.** William Edward Langdon, The Telegraph Department, Midland Railway, Derby.

5832. **Improvements in electricity meters of the pendulum class, parts of such improvements being applicable to other kinds of electricity meters.** George Hookham, 7 and 8, New Bartholomew-street, Birmingham.

5839. **Improvements in dynamo-electric machines.** Thomas Henry Allum, Guy Carey Fricker, and John Richard Bainton, 39, Montserrat-road, Putney.

5844. **Improvements in protecting telegraph, telephone, electric lighting, and other installations and instruments from damage by lightning or other high-tension electric currents, and in apparatus therefor.** Oliver Joseph Lodge, 6, Lord-street, Liverpool.

5867. **Improvements in connection with switches for telephone circuits.** Alfred Graham, 47, Lincoln's-inn-fields, London.

April 6.

5888. **Improvements in methods of measuring electric resistance.** Alexander Pelham Trotter, 2, Victoria-mansions, Westminster.

5894. **Conveying electricity or communicating with light vessels by electricity.** William Edward Blackburne, 22, Canning-street, Liverpool.

5904. **Improved means and apparatus for electrically communicating between trains and fixed points or stations.** William Willort Popplewell, 17 and 18, Southampton-buildings, Middlesex. (Felix Lefrancois, Eugene Manborgne, and Oscar Boin, France.)

5912. **Improvements in systems of suspending electric conductors.** Charles Joseph Van Depoele, 77, Chancery-lane, London. (Complete specification.) (Date applied for under Section 103 of the Patents Act, 1883, 10th September, 1888, being date of application in the United States.)

5913. **Improvements in devices for establishing electrical contact in electric railways.** Charles Joseph Van Depoele, 77, Chancery-lane, London. (Complete specification.) (Date applied for under Section 103 of the Patents Act, 1883, 7th September, 1888, being date of application in the United States.)

SPECIFICATIONS PUBLISHED.

1884.

9982. **Electric currents.** Abel (Zipernowski and another). (Second edition.) 8d.

1886.

2783. **Electromotors.** Jarman. (Second edition.) 8d.

1888.

3968. **Electric arc lamps.** King. 8d.

6928. **Electric switches.** Andersen and Tafe. 8d.

7901. **Electromagnets.** Horne. 4d.

17222. **Electric arc lamps, &c.** Paget. 8d.

1889.

375. **Electric glow lamps.** Bernstein. 6d.

2748. **Telephonic switching apparatus.** Bennett. 8d.

NOTES.

Royal Yachts.—*Truth* states that the "Osborne" is to be refitted with electric light.

Amiens.—Other installations are shortly to be put down in this town. Four of five thousand lamps are, it is said, subscribed for. The cathedral will be lit shortly.

Multiple Electric Lock.—A superintendent of an asylum has invented a lock by which all doors can be opened by the touch of a button, to be used in case of fire.

Institution of Electrical Engineers.—The next paper will be read on Thursday next, the 25th April, at 8 p.m., by Prof. Oliver Lodge, F.R.S., "On Lightning Conductors."

Railway Lighting.—The train on the Penarth branch of the Taff Vale Railway, recently lighted by electricity, has 50 12-c.p. Edison-Swan lamps, run off a dynamo driven by the axle.

Utilising Niagara.—A Bill has been introduced in the New York Legislature authorising the Niagara Electric Hydraulic Company to erect a plant at the falls, on the plan devised by Mr. Hamilton.

British Association.—The offices of the British Association at Newcastle are now on the ground floor of the Literary and Philosophical Society, Library-place. The honorary secretaries are Prof. S. H. Merivale and Dr. Bedson.

Honiton.—At the Honiton Town Council last week, it was decided to refer to the General Purposes Committee an application from Mr. H. J. Materface for leave to lay overhead wires, with a view of introducing the electric light into the borough.

Melbourne Exhibition.—Messrs. W. F. Dennis and Co. inform us that Messrs. Felten and Guilleaume (for whom they are sole English agents) have been awarded a First-Class Order of Merit in the electrical section of the Melbourne Exhibition.

A Prize for Inventors.—The Committee of the Parisian Press have had placed to their credit by M. Osiris a sum of 100,000f. for award as a prize to the author of the most remarkable work of art, industry, or public utility in the great Universal Exhibition.

Electric Goods Traffic.—Several of the street railways of America now run "freight cars" for goods traffic as well as their passenger cars. These have proved a great convenience to the inhabitants and a source of considerable income to the tramway company.

New Periodical.—We have been favoured with the first number of *El Progreso*, a weekly journal of politics, science, art, and commerce. It is printed in the Spanish language, and dates from Buenos Ayres, in the Argentine Republic. We wish it every success.

Electric Sewage.—The question of the electric treatment of sewage came before the Wolverhampton Town Council last week, but Alderman Gibbons thought that this system was not applicable to Wolverhampton owing to the sewage there being charged with waste acids.

Faraday Lecture.—The Faraday Lecture of the Chemical Society will be delivered on June 4th, by Prof. Mendeleef, in the theatre of the Royal Institution. The fellows of the society will entertain the Faraday Lecturer at a dinner at the Holborn Restaurant on the following evening.

Italy.—*L'Elettricità* announces that the public lighting in Milan is to be extended to the following thoroughfares: Via Durini-Verrière, S. Pietro in Gersate, Francesco Sponza, Corro di Porta Vittoria, as well as to the Via Meraviglia Maria alla Porta and the Corra Magenta.

Berlin.—The machines in the Mauerstrasse station, Berlin, are said to give satisfaction. They supply 3,000 incandescents. The difference of potential at the terminals is 120 volts, and the speed 730 revolutions per minute. Other dynamos of a capacity of 10,000 lamps are in course of construction.

Reuter's Company.—The report of Reuter's Telegrams Company shows net profits for the year ended December amounted to £1,222. 8s. 6d. The directors have transferred £3,448. 15s. 2d. from the reserve fund, and declared a dividend of 5 per cent. for the year, carrying forward a balance of £446. 1s. 7d.

Electric Water Indicator.—The Maidstone Water Company have accepted the tender of Mr. George Jennings, Lambeth, for a second set of patent electrical apparatus for indicating, in the engine-house at East Farleigh, the level of water in the reservoir of the Kent County Asylum, Barming, including lines between the two points.

Edison Exhibit.—The American journals announce that Edison will send to the Paris Exhibition a monster model of an incandescent lamp, 40ft. high, of which the bulb will be formed of 20,000 small lamps. This will, it is said, be flanked by representations of the French and American flags done in coloured incandescent lamps.

Hammersmith.—At the Hammersmith Vestry, the Law and Parliamentary Committee reported with reference to the application of the West Middlesex Lighting Company for the supply of the electric light to certain streets in the parish, recommending that under certain conditions the Vestry grant the application. The recommendation was adopted.

Reading.—At the last meeting of the Reading Town Council, applications from Mr. Yeatman (on behalf of Messrs. Laing, Wharton, and Down) to fix a further electric lamp at King's-road corner, and from Mr. Wyles (local manager of the South of England Telephone Company), to erect additional wires across the public thoroughfares, were granted.

Effect of Conduits on Price.—In tendering for the public lighting of the streets of New York, the electric light companies have doubled their rates where subways have to be used, on the ground that they will have to pay rent to the subway company. The price tendered for light from poles is 35c. per night; but with wires in the subways the cost is to be from 65c. to 68c. for the same hours.

A Note for Landowners and County Councils. With reference to the electric tramway in Richmond, Virginia, now celebrated throughout the civilised world, the Richmond (Va.) *State* says: We have now nearly 20 miles of track. The building of the electric line has given an impetus to suburban improvements which will eventually add much to the beauty of our suburbs and their taxable values.

Overhead Wires in New York.—The Mayor of New York has ordered the removal of all overhead wires along Broadway from Fourteenth to Thirty-fourth

Digitized by Google

street, the telegraph companies not having complied with the regulation to place their wires underground within the specified time. The work of removal commenced on Tuesday, a number of wires and poles in various localities having been pulled down.

The Telephone in France.—It is stated that on the 26th instant, the Chamber of Deputies will proceed to nominate the commission to report upon the reorganisation of the French telephone system. The members of the commission, who, by the way, are in favour of the proposal of the Government, will be MM. Saint Prix, Munier, Sarrien, Bernier, Goirand, Steenackers, Gobron, Million, Bizarelli, Lalande, and Georges Cochery.

Electric Theodolite.—The Italian papers report that an "electric theodolite" has been set up at Maddalena to defend the island of Caprera, communicating with a gun battery behind a high hill, and so arranged that the defenders can ascertain the position of invading ships, and fire over the hill at them, but cannot be fired upon. The arrangement appears to consist of a small camera obscura on the hill, connected by electrical contacts with the gun battery in the valley.

Electric Date and Time Stamp Company.—We are requested to state that there is no connection between this company and the Time Stamp Company, against whom a winding-up order was granted by Mr. Justice North on Saturday last. We understand that the ingenious instrument invented by Mr. C. A. Randall, which we recently described, is now being made in large quantities for the Electric Date and Time Stamp Company, and orders for these in large numbers are already in hand.

Electric Light for Vestrymen.—The Works Committee, at the meeting of the St. Martin-in-the-Fields Vestry, on April 4, reported on the tenders for the supply of fittings for the purpose of supplying electricity to the Vestry-room and lighting it. The Metropolitan Electric Supply Company and the London Electric Supply Company both tendered, and the Vestry accepted the tender of the first company to supply six 16 candle lamps for £12. 12s., and supply a current for £12 per annum. The report was adopted.

Electric Light Currents in the Telephone Wires.—On Thursday last the subscribers to the Chatham Telephone Company were considerably startled and alarmed by the continual ringing of the bells connected with the telephones. It was found impossible to stop the ringing and other noises which came from the instruments, and, on an enquiry being made, it was found that in altering one of the telephone wires it had been placed slightly in contact with the electric light wires, and this caused the unusual disturbances.

An Electric Light Cake.—At the recent celebration of Mr. Edison's forty-second birthday, the servants employed in his house and outbuildings, not to be outdone by the employés of the laboratory, presented him with a birthday cake of immense size and novel construction. It was about 2ft. in diameter and 12in. high. It bore the inscription: "Thomas A. Edison, 1889," in coloured greenish-white frostwork, and around its edges were 42 tiny incandescent electric lights, supplied from a battery placed in a cavity in the centre of the cake.

Lighting of a Public Laundry.—A public steam laundry has just been opened at Hertford for the town and district, replete with every appliance and convenience for carrying on a very extensive business. It has been fitted by Messrs. Bradford and Co. with washing machinery, with their most recent apparatus. The laundry is lighted by incandescent lamps, worked by a vertical engine of four h.p. nominal. The work, with entrance lodge and stables, has been carried out by a local builder, Mr. H. Norris, from designs by Mr. William White, F.S.A.

St. Louis Exposition.—In September next the International Exhibition at St. Louis, U.S., will open again, and exhibits of the latest improvements in electrical machinery have been promised from America, England, Germany, Russia, Spain, Belgium, and France. The whole northern nave will be electrical. An electric railway, with cars on different systems, will run continually. A coal-mine lighted by electricity will be worked by electrical coal-drills; mining stamps driven by motors, and other of the latest applications of electric power, will be shown.

A Long Span.—The new span of telephone wire crossing Dartmouth Harbour just erected by the Western Counties and South Wales Telephone Company, under the direction of the general manager, Mr. H. F. Lewis, is, as far as we know, the longest span of wire in England. The wire is 800 yards span (nearly half a mile), and is 200ft. above water-level. A very fine light wire of silicium-bronze (No. 17 gauge) has been used, and it has already stood two very severe gales satisfactorily. The strain on the wire is 58lb., and the weight of wire to each span is 24lb.

The Paris Exhibition.—The temporary installation, for the purpose of enabling the exhibition works to be proceeded with at night, which is being put down in the Champ-de-Mars by the Edison Company, consists of 45 750-c.p. arc lamps, distributed over the Palais des Beaux-Arts et des Arts Libéraux, the Dôme Central, the gallery of machines, and various other parts of the building. The motive power is divided into two groups, each group including a portable engine by MM. Weyher and Richemond, and a dynamo giving 75 volts and 223 amperes.

Effect of Legislative Telephone Rates.—A Bill to regulate the rate of charge for telephone was recently introduced by the Legislature for Kansas City. The effect has been that the Telephone Company made a bold move for freedom. It cut down its staff of linemen to ten, notified that all contracts will be cancelled as they fall in, and, if the Bill passes, they intend to remove all instruments from the city. As the company control 1,900 patents, and no other telephone company could work without them, the result of the attempt to reduce the rates is not encouraging.

Electric Yacht.—Yachting is as favourite a sport on the East Coast of America amongst wealthy merchants and others as on our own coasts, and over there electricity is to be applied in the service of these pleasure ships. An electric yacht is to be added to the New Haven Yacht Club, and accumulators will be used to drive a motor, so that the yacht can run in calm weather as well as when breezes blow. The bottom of the vessel is lined with lead to prevent damage from the acid, and the other cells themselves will serve as ballast. There to be 25 cells and a 6 h.p. motor, connected directly to the propeller. The motor will not be used when there is a good wind.

Tender for Lighting Galatz.—A despatch has been received at the Foreign Office from Her Majesty's Consul-General at Galatz reporting that the Municipality of that

Digitized by Google

town are prepared to receive tenders for the lighting of the town either by gas or electric light, and that the specifications of their requirements can be seen at the Municipal Offices at Galatz. The tenders must be sent in by the 25th May, O.S. (June 6), and must be accompanied by a deposit of 25,000f. in cash or Government securities. Applications in respect of this matter should be made in French or German.

Telephones for Divine Service.—With the consent of the pastor and deacons of the Congregational Church at Tunbridge Wells, the South of England Telephone Company have been experimenting with their instruments with a view to perfecting the transmission of a religious service to distant and scattered parts of a locality. Telephonic communication having been established within the building, the service on Sunday was listened to by about a dozen people gathered at various points in the town. One or two doctors and chemists' assistants on duty at their respective establishments joined with the congregation in the service, as did also an invalid lady who has been bedridden for a long time.

Mr. F. J. Sprague.—The American journals announce that Mr. Frank J. Sprague, of the Sprague Electric Railway and Motor Company, will probably visit Europe during the summer. Mr. Sprague is one of the busiest men in the States just now, but in view of his disposal of the patent rights in England (with which the recent visit of Mr. J. B. Verity is said not to be unconnected), we may expect to see Mr. Sprague himself to look after pushing the motor trade here. English makers of motors had better wake up, and try to push their wares practically and in an active commercial spirit in this vast field lying open at their feet, or the wind will be taken out of their sails by the States in motors as, heretofore, in arc lamps.

Profits from Electricity.—The following comparative statement of the virtues of horse and electric traction is from a letter from the president of the Davenport (U.S.) Electric Railway, in the *Street Railway Journal*. The figures are for similar periods in 1887 and 1888. The road is a small one, equipped with four 14ft. Sprague cars, each with two 7½-h p. motors, and one 10ft. car; the gradient is 7½ per cent. The figures speak for themselves.

	1887. Horses.		1888. Electricity.		Increase Per Cent.	
	Gross.	Net.	Gross.	Net.	Gross.	Net.
Sept.	$1,374	$474	$1,997	$997	48%	110%
Oct.	1,232	302	1,903	1,121	57 „	270 „
Nov.	1,131	231	1,886	986	66 „	320 „
Dec.	1,283	353	2,022	1,122	59 „	220 „

Detroit Storage Cars.—The accumulator cars at Detroit are approaching perfection. The cars now run the whole day with one charge. A trial run, consisting of 11 round trips with the usual passengers, was perfectly successful, and a speed of 11 miles an hour was easily attained. The cars are fitted with 84 cells of the Detroit storage battery made by the Woodward Electrical Company. The manager is satisfied that with these 300 ampere cells round regular trips of 100 miles can be run with one charge, and the battery can be recharged at 300 amperes, or even more if necessary, in six hours. A most important item is that the manufacturing company guarantee to keep the battery in repair at 10 per cent. per annum during the full life of their patents—namely, 17 years.

Electric Lighting in Paris.—At a meeting held on the 3rd inst., the Municipal Council of Paris approved a scheme for the lighting, from the 1st of May to the 1st of November, 1889, of the principal boulevards and the Rue Royale, from the Place de la Republique to the Place de la Concorde. The lighting will be carried out in conformity with the agreement made between the Société Popp, the Edison Company, and the Société Anonyme de le transport de la Force par L'électricité. At the same meeting the following gentlemen were appointed technical members of the Commission of the Municipal Lighting Station: MM. Mascart, Potier, Hospitalier, and two delegates nominated by the Syndicat professionel des Electriciens, and the Chambre Syndicale des ouvriers électriciens.

The Electric Omnibus.—Before the London County Council last week, the committee reported that they had had before them a letter from the Commissioner of Metropolitan Police, stating that an omnibus propelled by electricity occasionally passed through some of the streets of London within the hours prohibited for locomotives, such prohibited hours being specified in by-laws made by the late Metropolitan Board in the year 1879, under the powers given by the 31st section of the Highways and Locomotive Act, 1878. The Commissioner of Police desired to be informed whether the Council was of opinion that any action should be taken. The committee recommended that the Commissioner of Police be informed that, in the opinion of the Council, there is no necessity, at all events at present, for any action to be taken with respect to the vehicle referred to. The recommendation was agreed to.

The Electric Duel.—The Westinghouse Company having taken no notice of Mr. Harold P. Brown's challenge to an electric duel to prove comparative safety, this gentleman returns to the charge with respect to economy, and challenges the Westinghouse Company to a trial at the electrical testing bureau of the Johns Hopkins University, to test the accuracy of their statement that they give 50 per cent. more light per pound of coal than is given by any direct system of lighting. The plant of the losing company to be presented to the university. Mr. Brown will use a Thomson-Houston direct current plant, and if the Westinghouse prove 50 or even 25 per cent. the better, Mr. Brown will pay all expenses. In event of refusal, Mr. Brown announces his intention to buy a Westinghouse plant and get it installed by former Westinghouse employés for the test.

Water Gas.—In a note on thermo-batteries in this journal for June 29th last year (p. 605), Mr. J. W. Swan alluded to the probability of extended use of Mr. A. Wilson's "water gas," a gas obtained from water by blowing a mixture of steam and air through a column of incandescent carbon. We notice that Mr. Wilson, who has for some years been manufacturing and using his water gas at his house and office at Stafford, has disposed of his patent rights to the British Water Gas Syndicate, Limited, and will leave Stafford to become their general manager and chief engineer at Leeds. Mr. Wilson is also engaged in the manufacture of "producer gas," in which coal is transformed into gas, reinforced by the decomposed water in the above manner. By this process a ton of coal produces 150,000 cubic feet, or fifteen times the volume of ordinary lighting gas.

Electric Search Lights.—Colonel Burton, R.E., Superintending Engineer, 1st Circle, at Madras, has sent in an indent to the Director-General of Stores in England for three electric search lights for use in Madras. Each apparatus is to work independently of the other two, and

Digitized by Google

is to be provided with three or four branch reflectors, for use at some little distance, probably 150 to 300 yards from the engines and dynamos. The lights are to be of the pattern used on shore during the sham night attack made by Her Majesty's ships in Portsmouth, on the occasion of Her Majesty's review of the Fleet in July, 1887. They will be used by the military authorities, and the Admiralty will be consulted as to the special kind considered most suitable. The places at which the lights will be erected are to be selected hereafter. The Public Works Department will erect the necessary masonry works, etc.

The Liverpool Tramways.—We announced some weeks ago that the directors of the Liverpool Tramways Company were desirous of substituting mechanical haulage in place of horses on their line. We are now informed that after the most careful consideration of all the various systems of mechanical traction, Sir David Radcliffe has advised his board that the system of "self-contained" accumulator cars which he recently inspected at the Electric Traction Company's Barking-road installation is the best adapted for tramway work, and the Liverpool company have entered into arrangement with the Electric Traction Company and the North Metropolitan Tramway Company to supply them at once with an experimental car, together with the necessary electrical equipment, similar to those which are now working on the North Metropolitan section between Canning Town and Green Gate, Barking-road.

Electric Light at the Suez Canal.—It is satisfactory to observe, says the *Daily News*, that there is one part of the world where the new illuminant is in very active development. We refer to the Suez Canal. The use of the electric light, which was at first restricted to vessels carrying the mails, has, since the new regulations, which came into operation two years ago, been allowed to all ships under certain conditions. The result has been that last year a total number of 1,611 steamers navigated the Canal with electric light as compared with only 395 in 1887. The numbers seem to increase regularly, for whereas in January, 1888, there were only 86 ships so lighted, there were in December as many as 178. The average time of transit by steamers traversing the Canal with electric light is stated to be 22 hours 26 minutes. The shortest time by a steamer with electric light for night navigation was 14 hours 55 minutes in 1888, as compared with 15 hours 5 minutes in 1887.

Electric Lighting of Tunnels.—We have already alluded to the successful lighting of "the Hoosac tunnel's bore" with thousands of incandescent lamps, to the great comfort and convenience of both passengers and employés. The tunnel of the New York Central Railroad underneath Fourth-avenue will soon be lighted in the same way, with strings of incandescent lamps at the height of the seats of the carriages. The annoyance caused by the blackness of some of the suburban tunnels in the daytime to City men travelling up and down the line is a source of real loss to the railway companies, many persons refusing to live in suburbs served by a railway having a long black tunnel, and whose carriages are often not lighted in the daytime. The Blackheath and Sydenham Hill tunnels are examples, and it might be worth consideration by railway directors if similar lighting to that undertaken in America might not prove beneficial to both passengers and themselves, for what conduces to comfort in travelling conduces to their own profits

Electric Lighting in France.—Dieulefit and Valréas, two small towns in the departments de la Drôme and Vaucluse, have a central lighting station which is not without interest. The two localities have a station common to them both at Béconne (Drôme), a distance of eight kilometres from Dieulefit and 15 kilometres from Valréas. Water power is employed, the turbines giving 50 effective horse-power. Three Zipernowski alternate-current dynamos of 24,000 watts each (2,000 volts and 12 amperes) are used. One serves the Dieulefit circuit and one the Valréas circuit. The third is in reserve. The difference of potential at the terminals of the primary circuit of the transformers is 1,750 volts, with 95 volts at the lamp terminals. The localities are connected with the dynamos by two overhead cables. That to Valréas is of silicium-bronze of 3·3mm. section and a length of 13,300m. That to Dieulefit is 3,700m. long, and 3·2mm. diameter. The lamps are Edison-Swan 16 c.p., and the price is put at about two centimes per lamp hour. The installation has been carried out by MM. Lombard-Gerin, of Lyons.

Electricity and the Gas Companies.—There seems every reason to believe that the gas companies are fully alive to the importance of taking Time by the forelock. One by one the continental companies are losing faith in the unsavoury element in which they deal, and, following in the footsteps of their American brethren, are girding on the armour of the enemy. At Montauban the gas people are applying for powers to establish a central station for lighting by electricity. At Angers, at Florence, at Perpignan, they are doing the same thing. We congratulate them, not upon their early appreciation of the superiority of electric over gas light, but upon the wisdom which leads them to even a tardy acknowledgment of defeat. They have made much capital out of *the occasional* failure of a badly arranged electrical plant. There was an outcry at Barnet, which gas echoes multiplied and made much of. We hear, however, that Madrid indulged in a howl of the most pronounced description, when, on one occasion, at 7 p.m., the city was plunged in darkness, and the *gas* manifested itself solely in the not-unfrequent form of smell.

Electric Snow-Ploughs.—Some of the Sprague motor lines are now being fitted with snow-ploughs for clearing the tracks in winter. These are driven by powerful electric motors, and it is estimated that these electrical ploughs will clear the tracks quicker than an ordinary plough drawn by a dozen horses, so that no snow, however deep, will be able to stop the running of the cars. In this connection it may be worth while to mention that a new form of screw rotary snow-plough has been introduced by Mr. Orange Bull, of Orangeville, Canada, the inventor of the rotary snow-plough, now often used on American railways, where the drifts are sometimes enormous, mounted in front of and driven by a special locomotive engine. In the latest form, illustrated in *Engineering News* (New York), for March 30, the plough is a huge taper knife-wheel, 9ft. in diameter, provided with four to eight knives, and revolving at 200 to 300 revolutions a minute. The knife-wheel is in reality a huge gimlet, forcing its nose into the snow, and pushing it backward, and then discharging it at a high velocity. The direction of discharge is regulated by the openings in the top of the closed-in case.

In the year 2000.—For an ideal representation of life in the next century nothing so powerful and interesting has been written, so far as we know, in its realisation of

Digitized by Google

the probable set of the evolution of social forces and the application of science to the uses of life, as the little shilling book, "Looking Backward," by Edward Bellamy (Reeves, 185, Fleet-street), in which a member of the present civilisation of Boston, in the year 1887, is mesmerised and accidently left in a trance in an underground fireproof sleeping-room. He awakes in the year 2000, and relates his experiences of both periods of life. The tendency of consolidations, trusts, and syndicates has grown into a vast and beautiful system of co-operative life; towns and habits of life are transformed, evolving into beauteous and satisfactory models. Electricity, of course, plays a great part in this rejuvenated paradise: one of the greatest differences being the absence of chimneys and smoky atmosphere by the adoption of electric fires and electric power. Selections of classical music are laid on to each house by telephone. Tubes for rapid transit of men and materials are laid in all towns and communicate with the villages, and the dreams of electrical engineers generally are carried out. Innumerable benefits on all hands accrue to society at large; and believers in the progress of human society (than whom none surpass electrical engineers in general) may be interested in following the prophecy of the clever author, in spite of the seemingly Utopian ideas which it embodies. The book has already achieved seventeen editions, a fair proof of its popularity.

The Central Station at Havre.—We have already announced that MM. Ch. Mildé fils et Cie have obtained the necessary authority to establish a central lighting station at Havre. The following details may be of interest: subscribers are to engage to take the light for a period of five years, with a minimum of 750 hours' lighting per annum. The price per 100 watts hour is fixed at 12 centimes, but an alternative arrangement is 5f. per carcel and 7f. for two carcels for incandescents extinguished at 10 p.m.; 70f. for 35 to 50 carcel arcs and 150f. for 120 to 150 carcel arcs extinguished at the same hour. Should the lamps be required to burn until midnight, the charges are 7f. 50c., 12f., 130f., and 275f. respectively. The fittings are supplied by the company, and burnt-out lamps will be replaced free of charge; broken glow lamps are to be paid for by the subscribers at the rate of 4f. each. These tariffs are reduced one-third in the case of the vessels belonging to the Municipality, and one-half for public lighting. During the continuance of the concession the company are to pay (1) a tax of 100f. per kilometre or fraction of a kilometre of underground mains, and (2) an abatement equal to 5 per cent. of the gross proceeds of the station. If the generating power is located in Havre, this percentage will be raised to 6 per cent. The company are to commence the work of construction within eight months, and to be ready for lighting within two years under penalty of forfeiture of the concession. The authorities reserve the right to take over the works after a period of ten years.

Accumulator Patents.—The decision of the American Courts has been given by Judge Cox on the accumulator patents, and invalidates several of the principal clauses while upholding others, and generally illustrates the inadvisability of claiming too much. The Court, while acknowledging Mr. Faure as an inventor of undoubted genius, considers itself forced to limit his invention to the application of an active material in the specific form of a "paint, paste, or cement," leaving any broader idea of the application of an active material generally out of consideration. Again, the fourth claim of Mr. Faure's patent, in which the grouping of the plates in a series of cells with a non-porous partition between them is claimed, is held to be invalid as it shows no invention, and does not come under the head of a new combination of old and well-known materials, but is held to be a combination which would occur to anyone versed in the art. In the case of the two Swan patents, the judge has decided that they are both invalid. The first of these relating to the application of the active material to a perforated plate is decided to be void on account of an anticipation due to Prof. Eaton, of Brooklyn, whose testimony went to show that he had perforated lead plates for that purpose before the issuance of Swan's patent. And again, the second patent of Swan for the arrangement of such perforations in regular order is held by the judge to constitute no invention, for the reason that it would be a most likely thing for anyone constructing such plates to so perforate them. The result of this decision illustrates the need for continuous and rigorous search for anticipations, and the absolute necessity of careful and accurate claims on the part of patentees.

Folkestone.—A stormy meeting was held by the Folkestone Town Council on Wednesday last week with reference to the introduction of the electric light. After much discussion as to whether members interested in the gas interest were to be allowed to vote (during which one of the aldermen left the room after "playfully tapping Mr. Logan on the head with his stick, in response to a humorous remark by that gentleman"), the Town Clerk read the report of the committee, which stated that, in their opinion, the terms of the provisional agreement between the committee and Messrs. Crompton and Co., electrical engineers, Chelmsford, were fair and reasonable. The lamps were to be arc lamps of 1,200 c.p., 43 in number, and the light was to be supplied by duplicate sets of plant, so that if one should fail half the district only would be in darkness. Private consumers were to be supplied at certain rates, and the wires were to be overhead or underground according to the dictum of the lord of the manor. They were, moreover, to be lighted half an hour after sunset and to be extinguished one hour before sunrise; and a penalty of 4d. per lamp per hour was to be paid by the company in the event of the light not serving. The terms were £24 per lamp per annum, paid quarterly. The contract was to be entered into for five years, from August 10 of this year. The cost of the electric lighting would be £1,032, against £1,034 charged for gas lighting, the former sum including everything. Mr. Thomson then moved the adoption of the report in the terms of the resolution as read by the town clerk, saying that the electric light would yield 51,600 c.p., as against 4,312 of gas. They had made every arrangement in the event of a failure, and, in fact, it amounted to this: that whereas the Corporation would only have to pay £24 per arc light, if they failed the amount recovered would be £62 per arc light. He thought, therefore, that they had safeguarded the town in every possible way; they had shown them that the cost was practically the same as that of gas, but that was not the only advantage of the introduction of the electric light. The number of hours the arc lamps would be lighted was 300 in excess of the gas lamps. Mr. Salter moved an amendment, which was supported by the Mayor, that the matter be adjourned, and the contract printed and circulated. The amendment, however, was lost, and the resolution was carried by one vote, six voting for, and five against, the resolution.

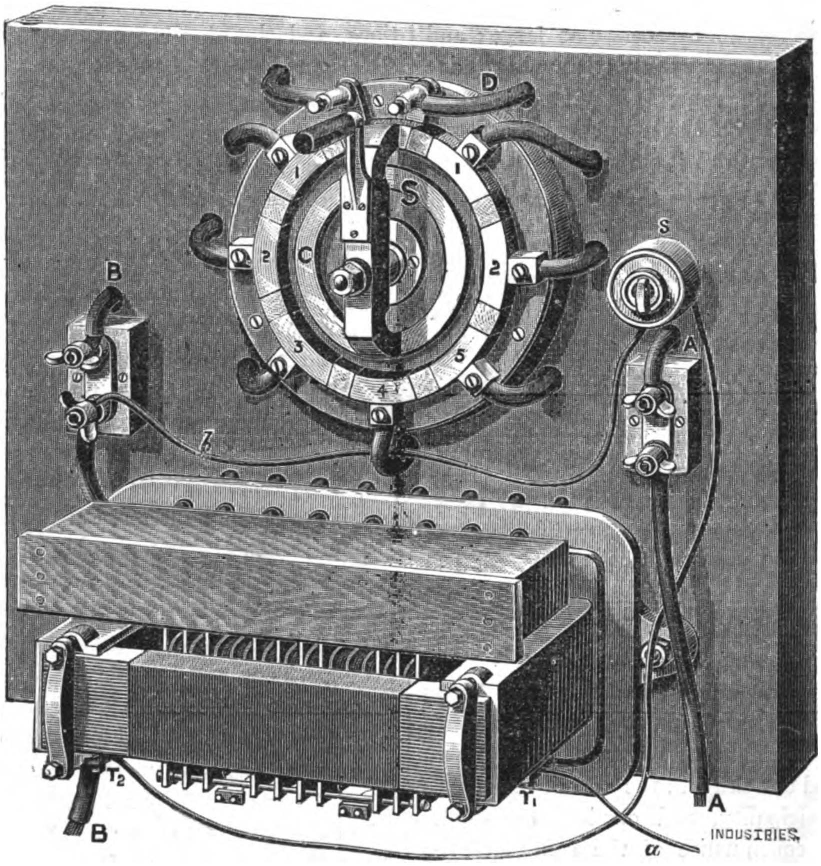
THE KAPP REGULATING TRANSFORMER.

Amongst the various advantages possessed by the system of alternating current distribution, is that of facility of regulation. One of the most important conditions in any system of central station lighting is that of keeping the pressure at the points of consumption as nearly as possible constant. In the direct current system, equality of pressure over the area supplied from a central station by feeders is generally obtained by the insertion of rheostats into these feeders; but this plan, besides entailing a considerable amount of watchfulness and labour on the part of the attendant, has the disadvantage of wasting energy. With an alternating current supply on the feeder system, the problem can be solved in a far more simple and less wasteful manner. Constant pressure at the feeding points, at all times and for all loads, can in this case be obtained by the insertion of a small transformer into each feeder, which raises the pressure at the station end of the feeder by the exact amount which is lost on the way in consequence of the ohmic multiple contact switch the upper part of the board. In this particular case it was desired to have means for either raising or lowering the pressure in the lamp circuit, and the secondary coil of the transformer has therefore been divided into seven sections, five of which are traversed by the lighting current in one direction, and are used for raising the pressure, whilst the remaining two are traversed in the opposite direction, and are used for lowering the pressure. The switch has accordingly seven contacts. When the handle is in the position shown in the diagram, the whole of the secondary coil is cut out, and the pressure supplied to the lamps is that given by the secondary coil of the main transformer, which serves this installation. If the switch-handle be moved to the right over the contact marked I, the current in the lamp circuit is caused to flow through one of the opposing sections of the secondary coil, and the available pressure at the lamps is reduced by 2 volts. If the switch-handle be further moved to the right over contact 2, the second section is brought into circuit, and the E.M.F. is reduced by 4 volts. On the other hand,



resistance of the feeder. The primary coil of the regulating transformer is connected with the terminals of the dynamo, and the secondary coil is sub-divided into a number of sections connected with a multiple contact switch. The current flowing to the feeder is led by means of this switch through one, two, or more of the sections of the secondary coil, and receives there an additional E.M.F. proportional to the number of sections inserted. The regulating transformer is so proportioned that, when the whole of its secondary coil is inserted, the increase of pressure is just sufficient to make up for the loss due to the ohmic resistance of the feeder. If the current flowing out is below the maximum, the switch is set to some intermediate point, so that in all cases the pressure at the distant feeding end is kept constant. This principle of regulation, which has been devised by Mr. Gisbert Kapp, primarily with a view to its application in central station work, is also suitable for regulating the pressure on the lamp circuit in private installations; and we illustrate above one of these regulating transformers, as fitted to the electric light installation at the town house of Sir David Salomons, Bart., which is supplied with current from the Grosvenor Gallery. The whole apparatus is placed on a board, and fixed against the wall, the transformer occupying the lower part, and the if the switch-handle be moved to the left, those sections of the secondary coil in which the E.M.F. is additive are successively brought into circuit, each step adding 2 volts to the available pressure at the lamps, so that by moving the switch-handle round to the contact marked 5, an increase of 10 volts over the pressure given by the main transformer is obtained. The connections are as follows: The service leads from the main transformer are brought to two terminals, to which the main lamp circuit is connected. Into one branch is inserted the regulating transformer, connection being made with the cables A and P. One terminal, T_1, of the primary coil of the regulating transformer is connected with one of the main terminals of the supply circuit, and the other terminal, T_2, is connected by means of the switch, *s*, and wire, *b*, with the cable P, coming from the other main terminal. The switch, *s*, is inserted so that the primary can be cut off if the instrument is not required. The cable P is connected by a fuse and lead, B, with the inner contact, C, of the multiple contact switch, S, and the cable A is similarly connected with the middle or zero contact of the switch by the lead, D. The other contacts of the switch are connected with the different sections of the secondary coil in the manner already explained. The advantage of this

Digitized by Google

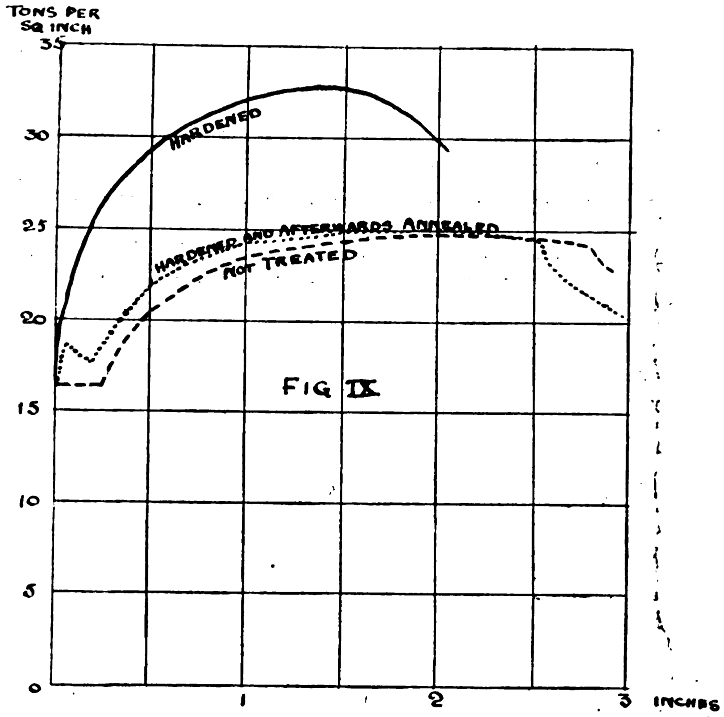
regulating apparatus is that without appreciable loss of energy, and by merely setting the switch to one or other of the contacts, the brilliancy of the lamps throughout the whole house can be regulated, whilst the regulating power is the same whether only a few lamps or the whole of the lamps in the house are alight. A rheostat or a choking coil could be used to lower (though not raise) the available pressure, but the effect would in either case be influenced by the number of lamps in use at any time. With the apparatus above described, the increase or diminution of pressure is, however, quite independent of the number of lamps in use, and the consumer is able to burn his lamps with either a higher or lower voltage than that supplied from the central station. The regulating transformer above illustrated has been made by Messrs. Johnson and Phillips, Charlton.—*Industries.*

PECULIARITIES OBSERVED IN TESTING MATERIALS.*

BY W. CLELAND, B.SC.

(Continued from page 300.)

This third period, which Tresca calls the period of fluidity, is first started by some point of weakness where greater than when the test is slow, so that the metal should flow very rapidly; but, owing to the great internal friction of solid bodies, the flow is hindered, the load is run up, and the metal breaks prematurely. Rapid testing, then, should give higher breaking results. Contrary to common projudice, the elongation under rapid testing is increased. It has always been held that when a specimen was broken suddenly the strain was very small, or even nothing at all. But some experiments made by Colonel Maitland at Woolwich have dispelled such erroneous ideas. He took different specimens of the same kind of steel—steel which, in an unhardened condition, stood 26 tons per square inch and gave an elongation of 27 per cent. on a length of 2in. The ends of one of his specimens were screwed into two blocks which slid on guides. This was allowed to fall, and after falling for some distance the top block was arrested by stops, and the specimen broke by the momentum of the lower block. The ultimate elongation in this case was 47 per cent. His other experiment consisted in screwing the specimen into plugs which fitted a tube. The space between the specimen and the tube was filled with gunpowder and guncotton. This was exploded, with the result that the plugs were sent out in opposite directions, and the specimen broken. The ultimate elongation was from 47 to 62 per cent. Very little or no local contraction took place; the extension was general. The explanation of this is probably due to what was mentioned above.†



the metal contracts, forming a smaller sectional area, and thus giving a greater unital stress. This gives rise to a difference of pressure, and the flow is quite comparable with that of fluids. Now, if by any means we can prevent contraction taking place, we will increase the apparent strength of the steel. In an experiment made to determine this, two specimens were taken from the same bar. One had the ordinary form, while the other was V shaped at the narrow portion, thus:

The diameter at the bottom of the groove was the same as that of the body of the ordinary specimen, and the result was that the former gave way with 30·5 tons per square inch, and the latter with 24·6 tons per square inch. If the bar tested was of Lowmoor iron, it was found that the section, instead of being fibrous in appearance, was partly crystalline, nearly 50 per cent. in the former, but a very small percentage in the latter. When steel was tested the fracture, which in the ordinary specimen was of a fine crystalline nature, became coarsely crystalline when the V specimen was tested.

Time, again, is an important element in testing. We can see how this is by going back to the period of "fluidity." Suppose the load applied at a rapid rate, and that local contraction has set in, the difference of pressure will be greater than when the test is slow, so that the metal should flow very rapidly; but, owing to the great internal friction of solid bodies, the flow is hindered, the load is run up, and the metal breaks prematurely.

I have already mentioned the point known as the elastic limit, or the point where the proportionality between stress and strain ceases; but this point is by no means immutable. For one test, and with the material in a certain condition, the point is quite definite, but if we go past the elastic limit in a test, and then relieve the specimen of the load, we would find by repeating the test that the elastic limit was raised. When we test the strength of steel wire, and an ordinary specimen of steel, we perceive a marked difference. The latter is very much weaker. This is due to the amount of work done on the wire, and to show that this is really the case, two specimens were taken from the crankshaft of the U.S. despatch-boat "Dolphin," one from the centre,

* Paper read before the Physical Society, Glasgow.

† Besides this experiment of Colonel Maitland's we have those by Mr. Bottomley (see article, "Elasticity," in *Encyclopædia Britannica*). Eight specimens of soft iron wire were tested, by applying a gradually increasing stress at intervals of 10 minutes. These broke with loads from 43½lb. to 46lb., and elongations varying from 17 to 22 per cent. Another specimen had 43lb. left hanging on it for 24 hours, and then broken, as before, with loads applied at intervals of 25 minutes. This broke with 49¼lb. and 15 per cent. elongation. Another had a load of 43lb. left on it for 3½ days, and broke with a load of 51¼lb. and elongated 14·4 per cent. Loading a bar, first with 40lb., and then gradually increasing the load over a period of two months, broke it with 57¼lb.

and the other from the surface of the shaft (The shaft had given way during the trial trip). The following were the results:

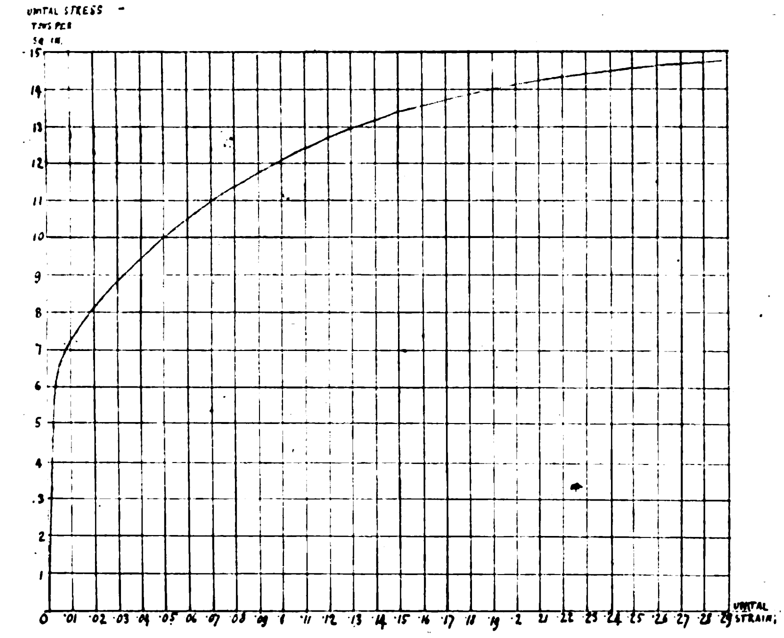
—	Elastic limit tons per square inch.	Tenacity tons per square inch.	Elongation per cent.
From centre of shaft	15·2	24·1	2
" surface "	14·3	35·7	18

THE TRANSMISSION OF POWER BY ELECTRICITY.*

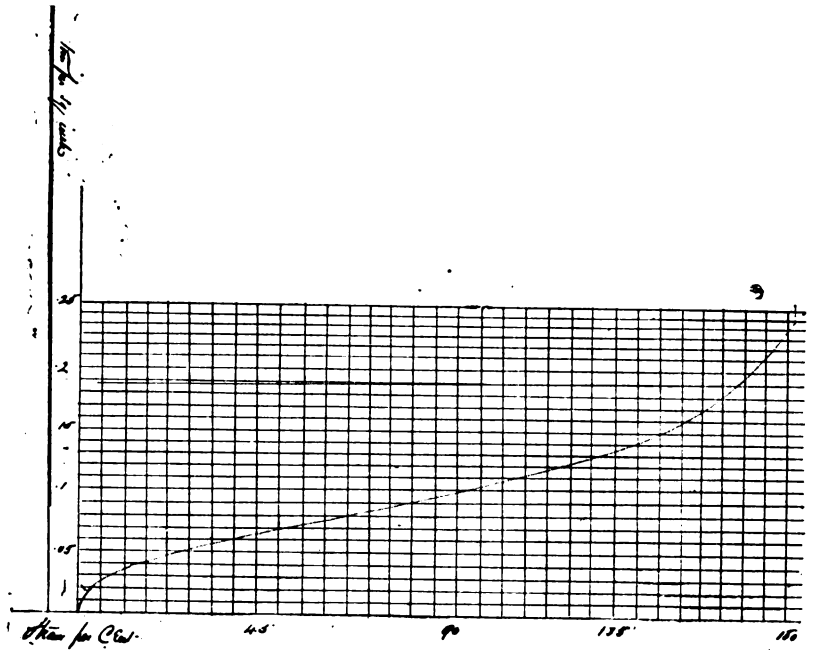
BY FRANK J. SPRAGUE.

(*Continued from page 293.*)

Let me give a practical illustration. Suppose we have a motor, the efficiency of which is 90 per cent. at 400 volts E.M.F., and when developing 10 h.p., and that we wish to transmit this 10 h.p. 5,000ft. from a station, and elect to lose about 9 per cent. on the line.



Autographic Test of Copper Wire. Dec. 3, 1888. Length tested = 24·38in. Diam. = ·021in. Area = ·000 35in. Speed = 1lb. per 48 secs.



Autographic Test of Indiarubber. Dec. 6, 1888. Thickness = ·15in. Breadth = ·083in. Area = ·0125 sq. in. Length = 1·73 sq. in. Load of 1lb. = 80lb. per sq. in. = ·036 tons per sq. in. Extension of 1in. = 13·7 per cent.

The difference is very much marked. We have also Sir William Fairbairn's experiments on the effect of cold rolling:

Material.	Tensile strength tons per square inch.	Elongation in 10in. per cent.
Rough rolled bar 1¼ diameter in ordinary state...	26·0	20·3
The same turned down to 1in. diameter in lathe ...	26·7	22·4
Bar, cold, rolled to 1in. in diameter	38·4	8·0

(*To be continued.*)

Our initial E.M.F. will be 440 volts, and we would have

$$C\,M = \frac{15{,}666 \times 10 \times 5{,}000}{400 \times 40 \times \cdot 90} = 54{,}396,$$

which is about equal to a No. 4 B.W.G.

Again, suppose we wish to transmit 5 h.p. over a distance of one mile on a complete metallic circuit of 45,000cm. allowing 5 per cent. increase of length for sag, and no leakage. Suppose further, that the initial line potential be 300 volts, and that we wish to have 250 volts at the motor terminals, it is required to find the commercial efficiency which the motor must have.

* A lecture delivered before the Franklin Institute, November 12, 1888.

Digitized by Google

Transposing our formula, we have,

$$a = \frac{15{,}666\, n\, l}{E\, v\, C\, M}$$

and substituting,

$$a = \frac{15{,}666 \times 5 \times 5{,}544}{250 \times 50 \times 45{,}000} = 76\%$$

This formula is useful in determining what we cannot as well as what we can do. For example, if we made the condition 10 h.p., all others remaining the same, the commercial efficiency of the motor would have come out 152 per cent., a most excellent machine indeed, and yet it is precisely this absurd thing that people practically say they will do in many of the statements which are made in relation to this subject. No science admits of more easy determination of conditions by plain and simple laws, and none brooks less violation of them.

In considering the transmission of power, some very curious and valuable facts may be demonstrated by a formula for determining the minimum cost of plant, where the amount of power at the generating station is practically not limited, and where there is no line loss from leakage, the line loss being measured simply by the fall in potential.

The cost of a plant of this character can be divided into five parts—that of the motors, the conductors, the line erection, the dynamos, and the power plant, whether water or steam. I will assume that the cost of the dynamos and motors is the same per h.p. or other unit, no matter what the E.M.F. used. While this is not strictly true, for all practical purposes, with large units, and speaking from the commercial standpoint, it can be so assumed. This being the case, for any given power the cost of the motor is a constant, independent of the potential used. With any given motor potential, the greater the loss on the line, the less the cost of the conductors, but the greater the cost of the generators. On the other hand, the less the loss on the line, the greater its cost, but the less the cost of the generating plant. It follows, then, that the least cost to the contractor is determined when the variation in the cost of the generator is equal to that in the cost of the line, and it is to a consideration of this fact that I wish to call your attention:

We have the formula

$$C\,M = \frac{1{,}492\, n\, m\, l}{E\, v\, a}.$$

Let d equal weight of one mil-foot of copper. Then the weight per foot of the copper of our conductor would be

$$\frac{1{,}492\, n\, m\, l\, d}{E\, v\, a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and the total weight for $2\,l$ would be

$$\frac{2{,}984\, n\, m\, l^2\, d}{E\, v\, a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

If b is the cost in cents per pound of copper (the cost of insulation being added to cost of copper), we have for the cost of the wire in the line

$$\frac{2{,}984\, n\, m\, l^2\, d\, b}{E\, v\, a} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

It is to be noted here that this cost b must be expressed so much per pound of copper. It may be that we have a line covered by an insulation of such character that for every dollar's worth of copper there may be 3dols. or 4dols. worth of insulation. For example, suppose that a 1/0 B. W. G. wire be used, covered with an insulation that should make it cost, say, 150dols. a 1,000ft. The actual weight of copper in the line would be only 350lb., which, at 150dols. market price, would make the wire cost 43 cents per pound of copper. It is this cost, plus the cost of freight and handling, which must be used as the value of b.

Let E equal the E.M.F. at the terminals of the motor; e, the motor E.M.F.; v, the fall of potential on the line; β, the commercial efficiency of the dynamo; E″, the E.M.F. of the generator; and n the number of h.p. developed by the motor. Then we have evidently

$$\frac{e}{E''}$$

as the ratio of the watt capacity of the motor and generator;

$$\frac{n}{a}$$

the h.p. of electrical energy delivered at the motor terminals;

$$\frac{E+v}{E} \times \frac{n}{a}$$

the h.p. of electrical energy delivered to the line, and

$$\frac{E+v}{E} \times \frac{n}{a} \times \frac{1}{\beta}$$

that delivered to the generator.

I think it advisable to make use of the term h.p. and commercial efficiency, for it is partly from the commercial aspect I wish to look at the problem, and it is the side which in business we must confront.

Let us further make K equal the cost in cents of the generators per h.p. required to drive them, and L the similar cost per h.p. of the steam or water plant, all of course erected in place—that is, with the cost of freight, handling, insurance, and erection added to the factory or shipping cost. Then the cost per h.p. of the generating plant complete would be:

$$\frac{E+v}{E\, a\, \beta}\, n\, (K + L) \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

If M is the cost of motor per horse-power developed similarly erected in place, the cost of the receiving plant would be n M.

We now have one element which is somewhat indeterminate, and is dependent chiefly upon distance and local conditions, and that is the cost of pole and line erection; and we will call this P.

Summing up our cost, we have the general expressions for the cost per horse-power delivered:

$$C = \frac{E+v}{E\, a\, \beta}\,(K+L) + \frac{2{,}984\, m\, l^2\, d\, b}{E\, v\, a} + M + \frac{P}{n}. \quad (7)$$

It is evident that this is variable, and since the costs of the motor and the line erection are arbitrary, the variation is narrowed down to the cost of the generating plant and the material in the line. It is here apparent, as already pointed out, that if we diminish the cost of the line by increasing the fall of potential, we must at the same time increase the cost of the generating plant, and, on the other hand, that if the loss on the line is reduced, its cost will increase, while that of the generating plant will diminish.

Differentiating with v as the variable, we have

$$\frac{dc}{dv} = \frac{K+L}{E\, a\, \beta} - \frac{2{,}984\, m\, l^2\, d\, b}{E\, a\, v^2} \quad . \quad . \quad . \quad . \quad (8)$$

or equating to zero

$$\frac{K+L}{\beta} = \frac{2{,}984\, m\, l^2\, d\, b}{v^2} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

which is the condition of least cost.

From (9) we have

$$v = 54{\cdot}6\, l \sqrt{\frac{m\, d\, b\, \beta}{K+L}}. \quad . \quad . \quad . \quad . \quad (10)$$

That is, with fixed conditions of cost and efficiency of appatus, the number of volts fall to get the minimum cost of plant is a function of the distance alone, and is independent of the E.M.F. used at the motor, a somewhat startling conclusion.

Substituting the equivalent value given by equation (9) in (7), we now have for the equation of least cost

$$C = \frac{E+v}{E\, a\, \beta}\,(K+L) + \frac{v}{E\, a\, \beta}\,(K+L) + M + \frac{P}{n}. \quad . \quad (11)$$

The first element representing the cost of the generating plant, and the second the cost of the wire per the horse-power developed by the motor. The cost of the wire is given as a ratio of the cost per horse-power of the generating plant. From this equation we have the relation:

$$\frac{\text{Cost of wire}}{\text{Cost of generating plant}} = \frac{v}{E+v}. \quad . \quad . \quad (12)$$

This is not, however, in a very useful form, and since the commercial efficiency is that with which we are concerned, we will introduce a term, designating it λ.

We have for the h.p. delivered to the generator

$$\frac{E+v}{E\, a\, \beta}\, n,$$

and n that taken out of the motor; hence we have,

$$\lambda = \frac{E\, a\, \beta}{E+v}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

or

$$v = \frac{a\beta - \lambda}{\lambda}\, E \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

Substituting the value of v in equation (11), we have a new form of the cost equation as follows:

$$C = \frac{K+L}{\lambda} + \frac{a\beta - \lambda}{a\beta\lambda}\,(K+L) + M + \frac{P}{n} \quad . \quad . \quad (15)$$

a still simpler formula. We also have the relation

$$\frac{\text{Cost of wire}}{\text{Cost of generating plant}} = \frac{a\beta - \lambda}{a\beta} \quad . \quad . \quad . \quad (16)$$

That is, with any fixed couple and commercial efficiency, the cost of the wire should bear a definite and fixed ratio to the cost of the generating plant.

But the query arises at once—is this so, no matter what the cost of the copper? And the answer is an affirmative one, and why this is so will soon be apparent.

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

With this number is given a Steel Engraving of the Grand Hotel at Paris. Hundreds of English and American visitors will be in Paris during the Exhibition Season this year, and a very large number will undoubtedly patronise this Hotel. The Artist has placed the trees more for effect than from nature, we should imagine, from our knowledge of the spot, otherwise he has succeeded in producing a pleasing effect.

THE CITY.

"All things come to him who waits." So says the proverb, while another proverb tells us that "while the grass grows the steed starves." In other words, different conditions of things have their appropriate proverbs. Micawber waited, and in his case something did turn up. Electric light engineers have waited, and worked, for the City authorities to acquire that right frame of mind to view the general lighting of the City by electricity as a necessity. Step by step the question has been fought, prejudices have been overcome, ignorancies enlightened, till the victory has been so far won that tenders are out for the City lighting. As regards this tender, it has been in the hands of those desirous of tendering sufficiently long for them to have become thoroughly conversant with its requirements, and no doubt it will be largely used in future as forming a basis upon which to build other specifications ; hence we have, for the benefit of those readers who have not an original copy, given the specification in full in our columns. The only change made in the wording of the specification will be found in the second clause, sub-sections 1, 2, and 3, where "as marked" is given instead of "as coloured," the original plan accompanying the specification having the districts differently coloured, a proceeding obviously impossible in a newspaper.

With regard to the specification, considered as a specification, we must insist upon the fact that its framers thoroughly understand its imperfections. It has not been drafted with a view of giving a perfect specification to the world, but simply and solely with a view to obtain what they want for City lighting. Neither destructive nor constructive criticisms are wanted, and if any man or firm feels aggrieved that the wording is not such as they would prefer, their best plan is to pocket their grievances and tender clearly and plainly upon the lines laid down in the specification. There is a good deal of latitude left to the contractor, the one obvious feature being that the authorities require lighting that shall be certain and sufficient. It is evident, too, that niggardliness in the question of cost is not to stand in the way; for the specification practically admits that a nett profit of 10 per cent. upon the capital embarked is not too much to be expected. After that return is reached provision is made for the consumer as well as the supplier to benefit. We direct attention to these matters, because there exists far too great a tendency in some quarters to specify the lines upon which it is desired to tender, rather than to tender upon the lines specified by the purchaser.

The work to be carried out under this specification is by far the largest that has been designed in this or any other country, excepting, perhaps, the Deptford installation for the London Electric Com-

Digitized by Google

pany, for whoever undertakes the supply of either district must make provision for general private lighting as well as general street lighting. The two will go hand-in-hand, with the additional provision for the distribution of power. There are about half-a-dozen firms, or rather there are only about half-a-dozen men who can carry out this lighting satisfactorily. Just as there are drawing-room soldiers, so there are drawing-room electrical engineers, highly ornamental, no doubt, but of little use in practice. It may at once be surmised that the ranks of the drawing-room, or rather schoolbook, engineer will furnish the critics unable to find any good thing coming from the City authorities. The latter, as well as the successful contractors, must be prepared to have all their plans pooh-poohed, and an infinity of suggestions put forward as to what ought and what ought not to be done. Interference has done enough harm heretofore, that would-be critics should take the advice of a celebrated writer upon the preservation of the teeth, who entitled his pamphlet "Shut your Mouth." The City authorities are keen enough business men to employ competent advisers, and if they act upon the advice given by competent men, insisting upon good work, and a just provision for emergencies, they cannot go far wrong. The advisers will not think for one moment of suggesting the tender being given to a set of company promoters, whose object is to float a company and clear out rather than embark their own capital, if they have any, in any legitimate work—they will rather incline to give the work to those who have had the most experience, and who have a reputation to lose rather than one to gain.

The half-dozen firms who are capable of being entrusted and of carrying out successfully work of this magnitude will, no doubt, consider well all the conditions of the case, and will take care that the conclusions of their own designers are discussed and checked by outside authorities, that all their calculations are correct, and that at the last moment no flaw or slip be found, such as is usually accounted for by haste or oversight. There ought to be no chance of failure, and there need be none, if the competing firms, in their anxiety to obtain the order, keep continuously in mind that on no account must prices be cut so low as to render it doubtful if the best work and the best materials can be put in for the money. It is not a case of "Oh, that will do"; it is "the best, and none other."

It may be purely a question of coincidence that just about the time when the City authorities have decided to issue tenders for electric lighting, the gas companies and the advocates of oil are showing all they can do in lighting. Special improved gas-lamps, and special oil lamps are to be placed, or are placed, in certain streets to show that lighting by these means can be made quite satisfactory, and, of course, more cheaply than by the newer illuminant. It is positively amusing how quickly jeopardised interests find how much they can improve their wares when the market they long held as a monopoly is threatened. We trust, therefore, that the electrical industry will follow the example of the gas industry, and instead of each member trying his best to show his trade competitors in the wrong, there will be more pulling together for a common object than of bitter rivalry to frustrate business. All firms cannot get these contracts, and the motto rigidly adhered to should be "Fight fair!"

THE EFFICIENCY OF METHODS OF ARTIFICIAL ILLUMINATION.*

BY EDWARD L. NICHOLS, PROF. OF PHYSICS IN CORNELL UNIVERSITY.

Of human industries of the present day none, perhaps, save those which have to do with providing the race with food, clothing, shelter, and fuel, is more important to the cause of material welfare than that which deals with the production of artificial light, and he who seeks a means of measuring the material civilisation reached by a nation might find an excellent criterion in the progress which it exhibits in the art of illumination.

The problem of comparing the various methods of artificial lighting which are in vogue at the present day is one of great interest, whether we view it from the commercial standpoint, taking the cost of production as our controlling factor, or from the broader basis of relative usefulness, cost being relegated to a secondary position, or, finally, from the purely scientific point of view. From whichever side we approach this question, we are led inevitably to the consideration of certain elements which are alike of scientific, utilitarian, and commercial importance.

At first sight the attempt to determine the relative value of two sources of light would seem to be a simple matter. The number of factors, however, which enter into such a determination is surprisingly large, and many of them are of a character which makes it difficult to give them definite and complete expression. Of these the greater part are indeed commonly left out of account altogether, for the sake of simplicity, and we content ourselves with an antiquated and totally insufficient measure of our sources of illumination, which we call candle-power. It is to these other elements which enter into the question of the character of artificial light—such, for instance, as have to do with its quality—but which are, as a rule, quite lost sight of, to which I would ask your attention this evening, together with a discussion of those which are commonly made use of in photometry. If, in doing so, I am led to speak of methods which belong to the realm of pure science, I trust that you will agree with me in thinking that the results are not unimportant even to those whose interest in the problem of the production of artificial light is purely utilitarian.

In the important question of the efficiency of a light-producing machine or process, the practice of to-day is very far from having reached that degree of exactness of expression which we demand in other cases of the transformation of energy. In electric lighting the energy expended is readily determined in absolute measure, or in that excellent practical unit, the watt. In lieu of any attempt to express the useful energy obtained, however, we still content ourselves in practice with that most unscientific unit, the candle-power, based upon a source of illumination which is particularly subject to fluctuations of intensity and colour. Even as used in the Bunsen photometer the shortcomings of the standard candle are sufficiently apparent, but no one who has not attempted to study it by methods which make it possible to detect changes of colour as well as of brightness, can fully appreciate its fickleness.

* A paper read before the American Institute of Electrical Engineers, March 12, 1889.

Digitized by Google

Such as it is, we do not, moreover, make the best of the standard candle as a basis of comparison of artificial lights. We speak of a 16-candle incandescent lamp, for instance, meaning oftentimes "mean spherical candle-power," and then we compare it with a petroleum or gas flame, measured in the horizontal plane only, much to the disadvantage of the electric lamp. The study of the distribution of intensities in accordance with the very complete system devised for that purpose by the Franklin Institute Committee in 1884, affords an invaluable means of comparing the performance of various types of incandescent lamps; but the adoption of "mean spherical candle-power" as obtained by that method is, to say the least, misleading when it comes to the comparison of electric lamps with candles, oil, or gas. It is to be hoped that when the present confusion of methods of measuring candle-power now existing in the electric lighting establishments in this country is supplanted by a recognised system, the fairer standard already established by law in England—viz., mean horizontal candle-power—may be adopted. It is, however, in the comparison of arc and glow lamps that the latter are put at the greatest disadvantage. Here we pit the incandescent lamp, using mean spherical candle-power as our basis, against candle-power measured at the angle at which the arc light sends out the greater part of its rays. Indeed, in too many cases it is not with the actual intensity, even in this most favourable position, with which we have to do, but with an estimated or "nominal" candle-power which the arc, in matter of fact, never approaches.

The electric arc stands quite alone for the purposes to which it is adapted, and need fear no rivals. It does not need to be estimated upon any fictitious basis, and the continuance of the pernicious practice of ascribing to it powers of illumination which it does not possess must, in a great measure, be charged to the account of the standard candle; for, with the best intentions in the world, the comparison of sources of light differing so widely in colour as the candle and the electric arc is nothing more than a rude approximation, leading by its very inaccuracy to the temptation of the grossest exaggeration.

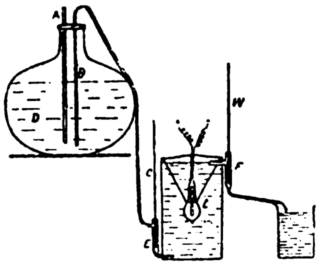

FIG. 1.

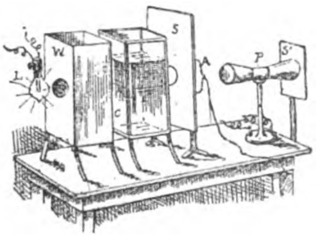

FIG. 2.

There are, fortunately, better methods of estimating the efficiency of a lamp than that which is based upon candle-power.

We may, for instance, determine the ratio of the energy of the light-giving radiation to that of the total radiation of the source of illumination. The efficiency of the incandescent lamp, according to this definition, has been recently determined by Mr. Ernest Merritt,* of the Physical Laboratory of Cornell University. Mr. Merritt followed two independent methods of investigation. In his first experiments the lamp was placed in a calorimeter constructed entirely of glass, Fig. 1, through which a constant flow of water was maintained. The temperature of the water upon entering and upon leaving the calorimeter was measured by means of the thermometers E and F. From this difference of temperature and the amount of water discharged in a given time, the heat absorbed by the calorimeter was calculated, proper corrections for loss of heat by radiations, etc., being applied. Now the water with which the calorimeter was filled is nearly transparent to the light-giving radiations from the lamp, and almost entirely opaque to the longer wave-lengths which constitute the so-called heat spectrum. To have assumed it to be entirely so, would, however, have involved very considerable errors, and the diathermancy of the calorimeter on the one hand, and its power of absorbing the luminous wave-lengths on the other, were accordingly carefully determined by methods long since elaborated and made use of by Melloni and by his distinguished English follower, Prof. Tyndall. By applying these and other necessary corrections, we are able to calculate very accurately in watts the non-luminous radiation from the lamp. The ratio of the total radiation, obtained either by submerging the lamp in a metallic calorimeter or by direct computation from the current and E.M.F. gives the actual efficiency of the lamp considered as a light-making machine. The result is not a gratifying one, when we compare this process with most others in which energy is transformed.

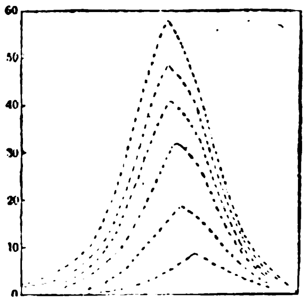

FIG. 3.

The efficiency of the best types of incandescent lamps, previous to the introduction of the recent three watts per candle lamps now in successful operation, which would doubtless make a somewhat better showing, was found to be rather under than over 5 per cent. at normal candle-power; the values ranging from 5 per cent. to 6·5 per cent. The last-named value for the efficiency was attained only at a temperature incompatible with any considerable length of life. The results obtained in this investigation are shown in Table I.,* and in the accompanying diagram, Fig. 3.

TABLE I.†

Lamp A.—Edison.

E.M.F.	W.	C.P.	L.	$\frac{L}{W}$	$\frac{L}{C.P.}$
74·2	34·6	0·9	0·18	0·005	0·59
91·6	56·2	4·8	0·68	·012	0·14
97·3	64·6	7·3	1·13	·017	0 15
100·3	69·3	8·9	1 62	·023	0·18
107 6	81·6	14·6	2·97	·036	0·20
109·3	84·4	16·3	4·57	·054	0·28
124·1	115·4	38·2	7·46	·065	0·19

In this table W is the total energy in watts; L the energy of the light, also measured in watts; and C.P. the candle-power.

(To be continued.)

SPECIFICATION.

SPECIFICATION OF CONDITIONS FOR SUPPLYING THE CITY OF LONDON WITH ELECTRICITY.

1. The main thoroughfares and public streets, etc., of the entire area of the City are to be lighted by electricity, and are divided into three districts. The contractors are at liberty to tender either for one or two of the districts or for the entire City. The Commission reserve to themselves the right of not accepting the lowest or any tender, or not accepting the whole or any part of any tender.

2. The area of the City which is to be lighted is divided into three districts as follows, and these districts are shown upon the plan accompanying this specification.

No. 1, West District, as marked on plan, comprising the area bounded on the north by the City boundary, on the east by Aldersgate-street, St. Martin's-le-Grand, St. Paul's-churchyard (north side), Creed-lane, and St. Andrew's-hill, and thence along Queen Victoria-street to Blackfriars Bridge; on the south by the Victoria-embankment; and on the west by the City boundary.

* Ernest Merritt, *American Journal of Science*, vol. 37, p. 167.

* Dr. Blattner, in an Inaugural Dissertation, published at the University of Zurich, gives similar values for the efficiency of the incandescent lamp. He finds, as the result of extended measurements with the glass calorimeter, that . . . "at the normal temperature of incandescence, where the intensity lies in the neighbourhood of 16 candles, the efficiency does not rise above 5 per cent. to 6 per cent." Emil Blattner: *Der Optische Nutzeffect der Glühlampen*, Frauenfeld, 1886.

† Tables I. and II., and Figs. 1 and 2, are taken from Mr. Merritt's paper, already referred to.

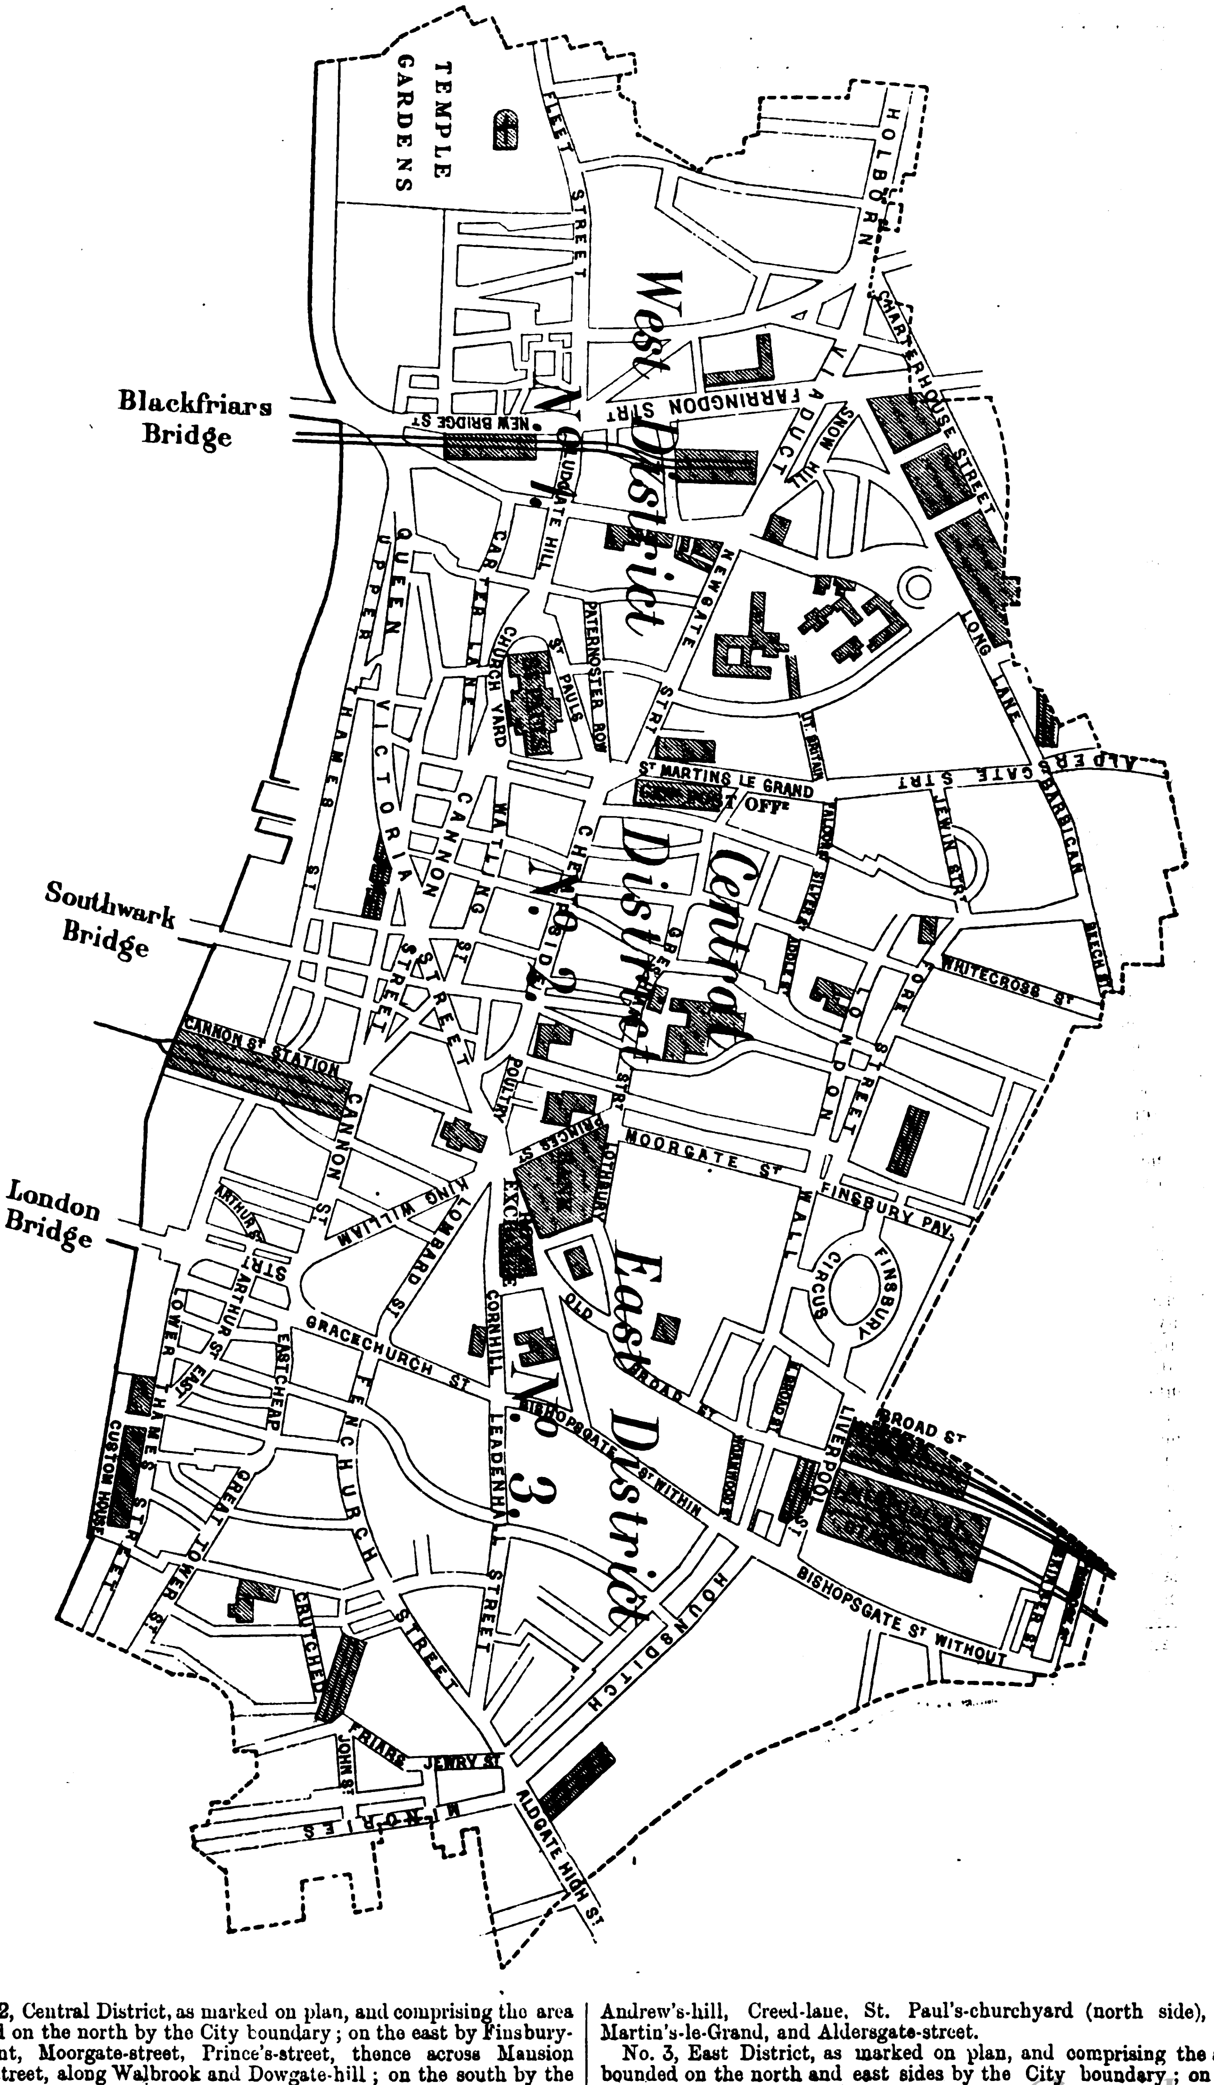
CITY OF LONDON ELECTRIC LIGHTING, 1889.



Plan Showing Proposed Districts.—Scale, 6 inches to a mile.

No. 2, Central District, as marked on plan, and comprising the area bounded on the north by the City boundary; on the east by Finsbury-pavement, Moorgate-street, Prince's-street, thence across Mansion House-street, along Walbrook and Dowgate-hill; on the south by the River Thames; and on the west by part of Upper Thames-street, St. Andrew's-hill, Creed-lane, St. Paul's-churchyard (north side), St. Martin's-le-Grand, and Aldersgate-street.

No. 3, East District, as marked on plan, and comprising the area bounded on the north and east sides by the City boundary; on the south side by the River Thames; and on the west side by Dowgate-

Digitized by Google

hill, Walbrook, Prince's-street, Moorgate-street, and Finsbury-pavement.

The whole of the main thoroughfares in each district are to be lighted, and the following is a list of those thoroughfares:

District No. 1 (west): Holborn, Holborn-viaduct, Newgate-street, Charterhouse-street, King-street, Long-lane, Snow-hill, Chancery-lane, Fetter-lane, St. Andrew-street, Shoe-lane, St. Bride-street, Farringdon-street, New Bridge-street, Old Bailey, Fleet-street, Ludgate hill, St. Paul's-churchyard (north side).

District No. 2 (central): Barbican, Beech-street, Fore-street, London-wall, part of (west of Moorgate-street), Gresham-street, Cheapside, Poultry, Watling-street, Cannon-street, part of (west of Dowgate-hill), Queen Victoria-street, Upper Thames-street (west of Dowgate-hill), Aldersgate-street, St. Martin's-le-Grand, St. Paul's-churchyard (south and east sides), Wood-street, King-street, Queen-street, Cripplegate-buildings, Milk-street, Aldermanbury and Aldermanbury-postern, Coleman-street, Basinghall-street.

District No. 3 (east): Liverpool-street, Houndsditch, London-wall (east of Moorgate-street), Old and New Broad streets, Bishopsgate-street-Within and Without, Lothbury, Threadneedle-street, Cornhill, Leadenhall-street, Lombard-street, Fenchurch-street, Aldgate, Aldgate High-street, Gracechurch-street, Mansion House-street, King William-street, Cannon-street, part of (east of Dowgate-hill), Eastcheap, Great Tower-street, Upper Thames-street (east of Dowgate-hill), Lower Thames-street, Arthur-street East, Minories, Prince's-street, Moorgate-street, Finsbury-pavement, Arthur-street West, St. Mary-axe.

3. An ordnance sheet (88ft. scale) is to be sent in by those tendering with each tender, upon which sheet must be marked every one of the existing gas lamps, distinguishing those which are upon brackets from those which are upon columns. It must also show clearly the positions of the arc lamps and the glow lamps which are intended to be substituted for gas lamps, and indicate clearly the gas lamps which will not be required whilst the electric lighting is in operation. A specimen plan is attached to this specification, showing how the various lamps are to be indicated upon the plans to be sent in by the contractor.

4. The contractor must give a complete description of the lamps proposed to be used, of the power in watts they consume, and of the light in candles they emit, both of the arc and the glow lamps. The lamps must be so placed that the light distributed over the public ways shall be as uniform as possible, and those tendering will have to demonstrate upon a plan and section, which is to be sent in with the tender, the relative intensity of this distribution of the electric and gas light. The standard of reference will be the illumination of a square foot of surface by a standard candle at 12·7in. distance.

5. The situations of the stations for the generation of electricity, if within the City, are also to be shown, and if not within the City, the points at which the main conductors are to enter the City.

6. The proposed positions of the mains and service pipes or leads, both for public and private lighting in every thoroughfare, must also be shown upon the ordnance sheet.

7. The system by which it is proposed to supply electricity must be fully described.

8. So soon as the main thoroughfares in the district have been lighted by electricity, the contractor must proceed to light the remainder of the public ways when called upon so to do by the Commission.

9. If the contractor should desire to light, in the first case, any portion only of the entire City, or, as the case may be, any portion only of any one of the districts, and to light the remaining portion of the City, or of such district or districts, at a subsequent date, the area which it is proposed to light first must be indicated clearly upon an ordnance sheet. The tender must also specify the dates and conditions under which the lighting is proposed to be extended by the contractor to the other parts of the City or district, it being, however, understood in all cases that the main thoroughfares, a list of which is hereinbefore given, are to be lighted by electricity in the first instance.

10. The contractor must specify the price per annum at which he will light and maintain each of the lamps, both arc and glow, according to the conditions of this specification.

11. The whole of the lamps are to be lighted nightly, including Sundays, from sunset to sunrise, and at such other times as the Commission or their engineer may consider necessary, on account of fogs or other emergencies. Payment will be made in respect of such extra lighting on the certificate of the engineer.

12. The existing system of gas lighting must not be interfered with, but the contractor may, in certain cases, be permitted, by the consent of the engineer to use any of the existing gas-columns or brackets. The existing gas-fittings are not to be disturbed, but must be maintained perfectly intact, in such condition that the gas lamps can be used at any time they may be required, and the full unobstructed light from the burners obtained.

13. If, during the carrying out of the works, the gas lighting shall be accidentally disturbed, temporary means of lighting shall be provided by and at the cost of the contractor.

14. Where existing gas standards are not used, as provided for by clause 12, then the contractor must provide and fix special columns or supports for the electric lamps. A design and description of them must be submitted to, and be approved by, the Commission before any are erected.

15. The electric lamps must be fixed on such standards as the Commission may approve. Should any variation of the positions of the electric lamps be deemed desirable, the contractor must fix them in such positions as the engineer may determine. The contractor must also maintain, paint, and keep in thoroughly good order all standards, columns, brackets, and lamps, at all times, to the satisfaction of the engineer.

16. If in the opinion of the Commission, any public way or portion of a district can be better lighted by glow lamps, or by arc lamps as the case may be, of a less intensity than that stipulated in the contract, the contractor is to change and maintain such altered lamps without further charge to the Commission, provided the total consumption does not exceed that stipulated by the contractor in the tender for lamps throughout the district or the City. But if a less light should be required by the Commission, then a reasonable deduction in the price to be charged annually for such lamps shall be made, as shall be determined by the engineer.

17. If the Commission shall at any time require any alteration in, or addition to, the mode of public lighting, after the lamps have been once fixed, either by placing the lamps in a different position, or by substituting a smaller number of larger lamps, or a larger number of smaller lamps, or by replacing existing lamps, columns, or brackets by others of a different nature, or otherwise, such alterations shall be carried out by the contractor, subject to the supervision of the engineer.

18. The cost of making the alteration referred to in clause 17, both as regards removing old lamps and fixing new ones, shall be borne by the Commission, and should any question arise as to the amount of such cost, it shall be referred to arbitration, the question being referred to two arbitrators, or their umpire, and subject to the provisions of the Common Law Procedure Act, 1854, or any other subsisting statutory modification thereof.

19. All mains, conductors, and service wires, both for public lighting and private supply, shall be laid beneath the public ways, in such places and in such positions as shall be prescribed by the engineer, should any deviation from the plans sent in by the contractor be deemed by the engineer desirable, and all such mains, conductors, and service wires shall be maintained by and at the cost of the contractor in good order and condition.

20. The contractor shall in no case break up or interfere in any way with the streets, pavements, or road ways until 48 hours' notice of the intention to do so has been given in writing. Exemption may be claimed from this rule on the score of emergency only, and the contractor shall abide by such conditions as the Commission may impose from time to time for the breaking up and reinstatement of the pavements so disturbed.

21. The contractor must take proper and efficient precautions for protecting from disturbance or damage all telegraph and telephone wires, and shall abide by all statutes, regulations, and enactments, and shall hold the Commission harmless from any damage that may arise. The contractor will also be responsible for complying with all the requirements of the Postmaster-General.

22. Should it be necessary for the contractor to run mains through districts which are not included in his contract, the contractor must do nothing that will interfere with the supply of electricity by other contractors in the other districts.

23. The contractor must, in all cases where practicable and permission can be obtained, make use of the subways for laying the mains, conductors, and wires; but where no subways exist they shall be laid, where practicable, beneath the footways.

24. All works, whether upon, above, or below the public ways, are to be done at such times and in such manner as may be necessary for the public convenience, and subject in every respect to the control and direction of the engineer, whose directions on all points shall be strictly complied with, and whose decision on all points shall be conclusive, final, and binding on all parties.

25. Before the expiration of —— months from the signing of the contract, the contractor shall commence the work necessary for installing and providing the system of public lighting in each district, and will from the time of such commencement diligently and without interruption proceed with such work, and will complete the system of public lighting in all the main thoroughfares, on or before —— months from the date of such commencement. [The time to be stated by the contractor.]

26. To secure the due fulfilment in all respects of clause 25, the contractor upon signing the contract shall deposit the sum of £1,000 in respect of each district with the principal clerk to the Commission, this sum to be placed on deposit at the risk of the contractor in one of the London joint-stock banks, and with the interest accrued thereon shall, in the event of the engineer certifying that default has been made by the contractor in commencing or completing the works, be retained by the Commission as liquidated damages, and the Commission may at their option terminate the contract by giving notice in writing to the contractor. In case the engineer shall not make any such certificate of default the deposit, together with the accrued interest, shall be repaid to the contractor.

27. When pavements are disturbed, the paving contractors to the Commission must be in all cases employed to reinstate them, and they will do so at the contract prices which the Commission pay to the respective paviors and paving companies for such work, whether it be granite, stone, asphalte, wood, or other material, and any work which may be rendered necessary to the sewers, or their appliances, must also be made good by the sewer contractors to the Commission, at the cost of the contractor for electric lighting.

28. The contractor is to supply the electricity, conductors, carbons, glasses, lamps, attendance, and everything necessary for the effectual maintenance of the installation, and the lighting of the district, during the contract period. The whole of the plant and installation is to be the property of the contractor, and at the expiration or determination of the contract with the Commission for public lighting by electricity, all connections and fittings supplied or used exclusively by him for public lighting shall be removed by the contractor, and all paving, and everything else disturbed, shall be reinstated by, and at the cost of, the contractor. In the event of the contractor failing to remove the connections and fittings, and restore the paving, the same may be removed and restored by the Commission, at the cost of the contractor,

Digitized by Google

29. So far as the Commission are able to do so, they will grant to the contractor the exclusive right of supplying electricity for private purposes within the district during the term of the contract. The contractor will be required to supply electricity to any owner or occupier of any premises within a distance of 25 yards of the mains, provided the owner or occupier enters into a fair agreement to defray, or divide, the cost of the service main, and to pay for the supply of the electricity. The contractor can charge the consumer for the amount of electricity supplied either (1) by meter, or (2) by agreement. (1) If by meter, the charge will be either by the actual quantity of energy supplied as measured in "units"—each unit being equivalent to 1,000 watts per hour; or by the mean average current expressed in amperes per hour, multiplied by the number of hours of supply. (2) If by agreement, the charge will be at the rate of so much per annum per standard lamp of 50 watts. The contractor will be required to specify in the tender the mode of charging selected, and the rate of charge.

30. At the expiration of determination of the contract for public lighting, the contractor is to have the right to continue to supply electricity for private purposes within the district, and to enjoy free way-leave, so far as the Commission are able to grant it, for all mains and service leads, concurrently with other parties, subject to the conditions for regulating the laying of mains and other works, and provided the contract has not been determined by the Commission for the following reasons: (1) under the 26th or 39th clauses, (2) in consequence of the contractor ceasing to supply electricity for private purposes for a continuous period of one month.

31. The Commission may at all times whilst the contract is in force test the condition and efficiency of the mains and conductors for insulation and conductivity in such manner as they deem desirable, and the contractor shall afford every facility for this purpose, and shall provide proper testing places and testing conveniences, and shall repair any defect that may be detected within a certain specified period, in default of which a penalty of £20 per day will be exacted so long as the defect continues.

32. The Commission may forbid the use of any main or conductor which they may consider dangerous to public safety, and may order its removal.

33. In the event of temporary failure in the electric lighting, the Commission are to be at liberty to light the streets by gas, or any other method, and all expenses consequent upon their so doing shall be paid by the contractor on demand, or the same may be retained out of any moneys due or that may become due to the contractor. The contractor will be liable to a penalty of 40s. per lamp for any and every instance of failure, or default in supplying light in any public lamp for any period exceeding five minutes, without prejudice to the rights of the Commission under clauses 37 and 39.

34. The contractor will be held responsible for any accidents or damage that may arise from imperfect lighting, or from laying or fixing conductors, lampposts, brackets, or from any cause whatever which may arise from carrying out this contract, and shall hold the Commission harmless for all consequences that may ensue.

35. Payment will be made at the end of every six months, upon the certificate of the engineer that the contract has been duly fulfilled, and the first half-yearly payment shall be made at the expiration of six months from the commencement of the public lighting, unless such period occurs during any vacation of the Commission, in which case the money shall not be paid until three weeks after the meeting of the Commission held next after such vacation.

36. If the profits arising from this contract exceed a cumulative dividend of 10 per cent. per annum upon the capital invested, the excess is to be divided equally between the contractor and the consumer. In other words, the contractor will not be entitled to pay a dividend of over 10 per cent. per annum, calculated from the commencement of the contract, unless at the same time the cost of the supply of the electricity to the consumer is reduced at the rate of ½d. per unit, as per schedule, for each 1 per cent. added to the dividend.

37. The duration of the contract for public lighting is for a period of 21 years from the completion of the lighting in all the streets, and shall be subject to determination by the Commission if the lighting, upon the certificate of the engineer, is inadequate or inefficient, or if the plant and system have not been maintained in thorough efficiency, any dispute as to the inadequacy or insufficiency of the lighting, and of the maintenance of the system, to be referred to arbitration, without prejudice to the rights of the Commission under clauses 26, 33, and 39.

38. The Commission shall have the option, by giving three months' notice in writing, prior to the expiration of the term of 21 years, to renew the contract for public lighting for a further period of seven years, and so on from seven years to seven years by giving a similar notice. Each renewal is to be subject to any revision of terms which the success of the contractor or the improvements introduced in supply or lighting may suggest.

39. In the event of the contractor failing, after receipt of due and formal notice at three separate times, with proper intervals, to comply with the conditions of the contract, to maintain the plant, mains, and conductors in proper order, and to provide sufficient electricity, the Commission shall have an immediate power to determine the contract as to public lighting, and to order the removal of the mains and conductors, whether used for private or public lighting. Any dispute as to the inefficiency of the lighting, or as to the failure of the supply, is to be referred to arbitration, without prejudice to the rights of the Commission under clauses 33 and 37.

40. Power is to be reserved to the Commission to acquire the undertaking and works, by purchase at the end of 21 years, or each succeeding seven years, on giving six months' notice, in accordance with section 2 of the Electric Lighting Act, 1888.

41. A contract embodying this specification, and such other provisions as may be deemed necessary by the Commission, is to be entered into by the contractor.

42. The contractor is to fill in his tender upon the following form. He may, at the end of such tender, give any descriptions or make any remarks he thinks proper, or anything that he may consider illustrative of his tender.

FORM OF TENDER.

To the Honourable the Commissioners of Sewers
of the City of London, 1889.

Gentlemen,

hereby undertake to light the district No. , coloured on the accompanying plan, in accordance with the accompanying printed and signed specification, on the following terms—viz.:

(1) Description of the lamps and their power; (2) the system on which it is proposed to supply electricity; (3) date of commencement of work and of completion of public lighting; (4) date within which the remaining portion of district or City shall be lighted completely under clause 9; (5) price per annum, under clause 10, of (*a*) arc lamps, (*b*) glow lamps; (6) mode and rate of charge for a supply of electricity for private purposes.

UNDERGROUND CONDUITS AND ELECTRICAL CONDUCTORS.*

BY JOHN B. VERITY (MEMBER).

My object in bringing this subject before you this evening is to promote an interchange of opinion and experience concerning one of the few remaining problems connected with the general distribution of electricity in our cities. Since I began to write this paper on my return from America, much information has appeared in the electrical press, and the close attention now being paid to the matter in America is equalled by a like spirit of enquiry here. The outcry against overhead wires has been gaining in force, and although the numerous objections urged are devoid of solid grounds, there is a general feeling that any considerable extension of overhead cables for electric lighting is impossible, both on account of the difficulty, and no inconsiderable expense, in procuring wayleaves, and also the attitude taken up by the Board of Trade and others to put a stop to them. Overhead wires in this country may therefore be simply considered as a temporary measure to admit of the electric supply companies getting to work, and permitted only on the distinct pledge of the removal of such wires within a certain period.

The time allowed for the execution of underground works in provisional orders and licenses, although as long a period as could be obtained, is all too short, and a thorough discussion of the subject at the present time, in its numerous aspects, is highly advisable to enable it to be afterwards promptly and adequately dealt with.

In three months we may reasonably conceive that certain electric supply companies will be under legal obligations to at once face the problem of putting high-tension electric conductors underground. It will be no petty attempt narrowed down to a small area, but in two special instances the undertaking is proposed to be carried out on a large scale by companies of adequate financial resources, and with supply stations already erected or in process of erection.

"Is failure probable?" may seem a singular question to put here, but it is a necessary one, leading up to the various difficulties to be encountered, and in view of the alarmist statements at the recent Electrical Convention in Chicago, one that deserves prominence. Mr. Lynch's paper, giving the results of the working of underground cables, and which was practically the only part of the meeting reported in the English papers, showed but one side of the case, and from the discussion following it (and which appeared in the *Electrical World*, March 2) much was to be learned. Many of the companies operating underground cables had from some cause or other not given their opinions, and the failures alluded to were in several instances traced to defective conduits, insufficiency of insulation, poor insulation, imperfect jointing, and cheap work. Cheap work has damned electrical enterprise before now, and it behoves us all to guard against a recurrence of it. Anything also on the subject of conduits and underground electric conductors emanating from American electricians has to be carefully sifted, as not even are our Unionists and Home Rulers more defined than certain "overhead" and "underground" men in America. The overhead men accuse all the underground men of being interested in some of the dozen forms of conduits put forth, the underground men retaliate by saying, "You don't want to go underground," and "you boldly say we cannot go underground."

In England we stand on a different footing altogether; if much more electric lighting work is to be done, we must go underground, and having recognised that, how can it best be done? The necessity and best form of conduits are the first points for discussion.

The successful working of a system of underground electrical cables in a city must be linked to an arrangement of ducts, as the impossibility without such of getting at the cables for repairs, inspection, tapping, and alterations is evident. Even if the local authorities remained quiescent during any continual disturbance of our streets on account of electrical conductors, commercial interest must prevent such occurring. The expense of opening up a crowded thoroughfare to lay underground cables is in many cases as great as the cost of whatever is being laid, while by using a duct this expense, once incurred, should not be again necessary. Again, if the cable be laid in the ground without a duct, it is necessary to armour it, and lay it down at first equal to all possible requirements, otherwise any extension of the lighting beyond

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

the capacity of the cable would necessitate a repetition of the whole original work. In this case, the first cost of such a large cable would be nearly as great as the smaller cable and duct together. Finally, the life of the best cable for high-tension currents cannot at the present be predicted, and this, together with the other reasons, undoubtedly prove that a conduit with a drawing in and out system is eminently desirable.

An ideal system for underground work is a brick subway, well drained and ventilated, and of sufficient size to permit of a man working in it; failing this Utopian arrangement, what comes next best? In New York, where the matter has been placed in the hands of a Board of Electrical Control, they start out by saying that a conduit or subway for electrical conductors is nothing more than a mechanical protection for the wires within it, and a convenience for placing or putting them underground. In their experience of three years the Board of Electrical Control have naturally tried and abandoned many conduits. In a room of the Telephone Building, New York, occupied by the Subway Construction Corporation, there is a heap of experience—experience gained at no little cost—that it would be of advantage for engineers who lightly propose undertaking such work to see and meditate on. Wooden conduits, bitumen conduits, asphalte conduits, earthenware conduits, samples of underground conductors, all are here in what is termed the museum, and afford a collection of failures most instructive as to what not to do.

In many instances, however, the conditions there would not apply to England. At present we have no system of steam-heating with leaky pipes, causing trouble wherever they go. Again, here we have not those great extremes of heat and cold, the frost compelling conduits to be laid at an average depth of 4ft., and the heat causing various troubles with asphalte and bitumen conduits. At the same time from the numbers of miles of conduits laid down there should be something to learn, and I therefore propose instancing some of the more important conduits known in America and elsewhere.

Conduits are divided into two classes: the so-called solid conduit, and the hollow conduit. Solid conduits are useless considering here, as they practically consist of cables bedded in asphalte or bitumen, which means ripping up the ground, and breaking the enclosing mass if alterations are required. With hollow conduits, the difficulties to be encountered seem to be to provide a smooth channel with convenience for drawing in and out to prevent explosions through accumulation of gas, and to keep them reasonably dry and water-tight.

In the discussion at Chicago it was stated that in one instance it was necessary to keep a blower going to ventilate an iron conduit, while several authorities appear to consider it advisable on dry days to take off the manhole covers. Accidents have, of course, occurred from conduit explosions, and the engineer of the United States Electric Lighting Company instances one where the manhole covers of the conduit were blown over the roof of a four-storeyed building. But in England, again, the work done by the gas companies is far better, and the leakage in our streets is not in any way to be compared with the quantity of illuminating gas which wanders fancy free through the soil of many cities in the United States.

It appears desirable that conduits should be ventilated; and the form adopted, where possible, is to ventilate them by means of a pipe running into the base or up the interior of the street lamp-posts. With regard to keeping them water-tight, this is another constructional question, surely capable of being properly dealt with.

Many of the complaints of leaky conduits and ultimate failure of cables I trace back to the Dorsott conduit.

This, one of the earliest forms of conduits, is built of blocks formed of a combination of cold tar pitch and fine gravel, cast with tubular openings 2½in. in diameter running through them from end to end. They are jointed by pouring soft mastic into the cracks between them, and the blocks made to adhere to this by warming their ends with hot irons and allowing them to cool, after being well set. To prevent the melted mastic from closing the ends of the passages, tubular pieces of paper are inserted, making a sort of internal sleeve coupling. The conduit so formed terminates in brick manholes at the street crossings. The objections to this conduit are that it is brittle, porous, inelastic, and cracks with changes of temperature, so that it is not likely to be made water-tight with average workmanship.

Creosoted wood conduits have been extensively used in the States, and have been a leading cause of trouble and failure with lead-covered cables. A chemical action takes place between the crude creosote and the wood, setting free acetic acid and carbonic acid gas, which, reacting on the lead pipe, converts its surface into a film of acetate of lead; the action continuing until the entire sheathing is converted into carbonate of lead or white lead. Creosote is also said to rot rubber. There are, of course, ways of overcoming such troubles, but as I do not think we shall be disposed to use creosoted wood conduits in this country the matter need not be given much prominence here.

The difficulty of obtaining a conduit that shall be anything more than a mechanical protection for the cables is certain to be great, as however good the insulating material forming the conduit may be, and however water-tight the joints, there is a difficulty in excluding dampness unless it is practically airtight, as damp air enters the conduit and condenses on it.

Several conduits have been made, however, with a view to afford electrical as well as mechanical protection to the cables. The Callender bitumen conduit, for instance, is well known here. It is being extensively laid down by the Chelsea Electric Lighting Company, and 500 yards of it is being tried by the Metropolitan Electric Supply Company. For high-tension currents its use is doubtful, but, perhaps, in the discussion something may be said on this point.

Vitrified 3in. sewer pipes laid in concrete with cement joints have been used in some instances for underground work.

(To be continued).

BOARD OF TRADE ENQUIRY.

Major Marindin, C.M.G., R.E., on behalf of the Board of Trade, resumed the enquiry at the Westminster Town Hall, on Wednesday, April 10th, for the purpose of hearing, on the part of a number of electric lighting corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

The case of the Metropolitan Electric Supply Company came on for hearing.

Mr. C. A. Cripps, who represented the Company, said he hoped to put shortly before the inspector on the part of the Metropolitan Electric Supply Company, Limited, their views with regard to the provisional orders which they were now asking from the Board of Trade. He would like to state at the outset, in order to make his address as short as possible, that there seemed to be two main points that could be very easily established to the satisfaction of the Board of Trade. The first was that the company he represented were in a thoroughly sound financial position, that they were supported by men in financial circles, that they had ample capital for all that they proposed to undertake, and that if additional capital were necessary they would have no difficulty in finding it. The other point he hoped to make equally clear was that the system proposed to be adopted by that company was the best and safest, that from an economical point of view it would stand comparison with any other system, and that as regarded safety and convenience to consumers, it stood in the best position of all. It had not been necessary for him to cross-examine on those points, or criticise at any length the views put forward on behalf of the London Electric Supply Corporation, and they were not desirous of doing so for the reason that they were so assured that when the inspector had heard their full evidence, they need not fear any competitive system put before him on behalf of any other company. They were not, in fact, concerned unduly to criticise any other system brought before him. The capital of the company was £500,000, in £10 shares. He believed that when the capital was issued, the amount subscribed was double what they wanted. Of the amount subscribed, £3 per share had been paid up, and the number of shareholders was no less than 700. They had expended a sum of £380,000. As he had already suggested—and he thought that Major Marindin would be satisfied with it when he had heard the evidence—whenever any further expenditure was necessary in order to carry out the obligations which the Metropolitan Company were desirous of incurring, there would be no difficulty whatever in finding sufficient financial support. The districts which they proposed to include for the purposes of electrical supply were comprised, in the first instance, under four provisional orders. As regards one of those orders, the North London order, he might state that after careful consideration, the directors of the Metropolitan Electric Supply Company did not propose in that enquiry to ask for any compulsory powers at all. In fact, in so far as that order was concerned, they withdrew that application, and nothing more would be heard about it. He mentioned that in anticipation of any of the views put forward by the local authorities, because that determination had been come to at a late moment. The first order upon which they would ask his (Major Marindin's) decision was the mid-London order. Now the mid-London order was shown by the map handed in, and his learned friend and the various local authorities had had full information as to what was comprised in the order. The area of supply constituted a number of parishes in the metropolis which he indicated on the map and over some of which the London Electric Supply Corporation also sought working powers. In order to supply electricity, he went on to say, to those various districts they proposed to have certain central or generating stations. It would be impossible to lay before the inspector any complete list of the generating stations until it was known for certain what districts they would be empowered to supply. They had made provisions as regarded a certain number of those generating stations, and he would give their names and situations as well as their capacity of lighting power. They had a station at Whitehall with a capacity of 12,000 lights. They had arranged for one in Sardinia-street with a capacity of 50,000, one at Rathbone-place with a capacity of 24,000, one at Manchester-square with a capacity of 50,000, one at Ecclestone-place with a capacity of 40,000, and one at Waterloo Bridge with a capacity of 20,000 lights. That was the present strength of the plant.

Major Marindin: Are these all arranged?

Mr. Cripps: Yes. The ultimate capacity of those stations if the lighting were required would be as follows: Ecclestone-place would be increased to 150,000, Waterloo-wharf to 75,000 lights. Whitehall station was running at that moment. Sardinia-street station would be ready in June, as well as that at Rathbone-place, while that at Manchester-square would be ready in July, Ecclestone-place in August, and Waterloo-wharf in September. In reference to the City, they had made satisfactory arrangements. In fact, they had practically purchased the wharf known as Greenmore-wharf. That would be a centre capable of supplying the City district. It was adjoining Southwark Bridge. They had up to the present time made no arrangements as to the plant there, but he believed that when they were carried out that wharf would be able to carry a plant capacity of 120,000 lights. He would now deal briefly with what their proposed system was, and say a few words as regarded its advantages and also certain suggested disadvantages. The Whitehall station supplied a very compact district, and was worked by means of the direct-current system and storage batteries. The electrical pressure over the district would be 100 volts, that in the engine-rooms being somewhat higher—between 100 and 110. There would be no transformers. As regarded the other generating centres, they would be all worked by what was known as the alternating-

Digitized by Google

current transformer system—that was to say, there would be alternating currents of high pressure in the mains converted by means of an induction apparatus into currents of low pressure on the consumers' premises. The pressure in the mains would not exceed 100 volts, and in the house not more than 50 volts. He thought that, properly speaking, all their mains would be called distributing mains, because there were not distributing centres in addition to the generating centres. He was also sure that the inspector would be satisfied after hearing the evidence that the variation in constancy of pressure would not exceed ½ per cent., that slight variation being attained by limiting as they did the district supplied from the various generating stations. He thought that the proposal was that those stations should be from one to two miles apart, and of sufficient size to fully utilise the staff employed, so that any suggestion that was made as regarded economy of labour would be fully met by the size of those stations, and from an economical point of view it would be proved that they would be gainers by not having long-distance mains through which to send their electric current. Each centre would be completely fitted with the best-known machinery and of the most modern structure. That, of course, would be a matter of evidence so far as it was gone into. The mains would be copper wires insulated with vulcanised indiarubber, and covered with some other insulating compound. These would be drawn into cast-iron pipes, and there would be at convenient intervals testing-boxes, in order to minimise any breaking up of the streets, while as regarded the private supply there would be junction-boxes. Now, the reasons which dominated the company in adopting and bringing forward their system as the best were twofold. First of all, there was the advantage of actual experience. He would bring before them Mr. Siemens, of Berlin, and Mr. Spencer, of America, to show that the system had been tried and carried out to a large extent in both Berlin and the United States, and that practically it had been found to be most efficient. Not only from Berlin and America, but also from St. Petersburg would he bring evidence as to its effective working. In addition to that the company had been advised by the most eminent experts and scientific men on the subject, and a considerable number of them would be called to give evidence to show on what sound foundations the Metropolitan Company stood when they brought forward their recommendations. The advantages of generating centres might be very shortly stated, so far as his opening remarks were concerned. There was no necessity to have a high pressure, and therefore there was little difficulty in insulating the cables and the transformers. The cost of their mains would be much less than the system of the London Electric Supply Corporation, and in case of any accident to them—which, of course, they did not apprehend—the area affected would be very much smaller. In reference to that he might make this statement: that by means of the various generating stations the mains would be constructed so as to overlap one another, so that if at any time there was any special pressure of work to be done, one or more of those generating stations would come to their aid and give the requisite supply. Then he was instructed to the effect (and this was a matter of scientific detail which he need not now go into) that their sub-division of machinery tended towards an economical method of working. Before he dealt, however, with one or two suggested details as regarded the Metropolitan Company's system, he would like to make one or two remarks upon some of the general points raised by his learned friend, Mr. Pember. Mr. Pember said that the company he represented hoped to make of Deptford a sort of electrical Beckton. He (the speaker) ventured to suggest that whatever might be the scientific advantages of the London Electric Supply Corporation's system as against that of the Metropolitan Company, there was no analogy between it and a gas company undertaking as regarded their having their supply in or out of London. The objection to a gas company in populous places was the noxious vapours given off in the manufacture of gas, and more particularly in that of residual products. There was no difficulty to overcome in generating electricity as regarded noxious gases and other matters which made it expedient to remove the gas companies out of London.

The first suggestion made, as to the greater costliness of having various generating stations, had reference to the price of coal. It was sufficient for him at the present time to deny the suggestion of the greater cost of coal, for Lord Crawford, in reply to a question put to him on behalf of the Metropolitan Company, said that he was aware that what was called the cheaper coal could be used at small generating stations, although he was afraid that from his experience at the Grosvenor Gallery some nuisance might be caused. The next suggestion—a rather small matter to test such a matter by—was that there would be some saving in supervision. If all the operations were under one roof no doubt there would be some slight saving, but if all the labour was equally employed and as economically employed in various generating stations as in one, he ventured to say that that saving would be absolutely inappreciable. And, after all, it must be borne in mind that those generating centres were both generating and distributing stations, whereas the other system, having one large generating station at Deptford, must have various distributing centres within the district supplied. As regarded noise, vibration, and smoke, they were in a very sound position indeed, and he thought it could be shown, as the result of what the Metropolitan Company had actually done with the machinery that they had put up, that the suggestion put forward in connection with the Grosvenor Gallery station would have no weight as regarded their proposed generating station. There was a time when suggestions were made that a nuisance was caused by the generating station at Paddington. He would afford full evidence in regard to the matter, and it would be found that their engineer had been enabled to deal with the difficulties. No doubt there were difficulties at first, but they had been overcome, and no complaints were now made. As to the Whitehall station, no trouble had arisen in connection with it. He would now pass on to the form of the proposed order. In the main, he believed it was in the modern form.

Major Marindin: Do the three orders all agree?

Mr. Cripps: Yes. He would like to say before dealing with the various provisions in the order that he fully adopted what his learned friend, Mr. Pember, said as regarded a monopoly. They were not seeking a monopoly of supply. They relied on their system being the best and most efficient, and felt satisfied that they should get an adequate and good custom. They were aware that under the Act of 1888, in the first section, it was specifically provided that a provisional order was not to be regarded as a monopoly, and he adopted everything Mr. Pember said on that point. He would just deal with the opposition that they had to meet with regard to the various orders. He would begin with the mid London one. They found that the City and the Metropolitan Board of Works withheld their consent on the ground of protection as regarded the bridges. St. George's, Hanover-square, and St. Giles' District Board of Works withheld their consent, and St. Margaret's and St. John's Vestry, Westminster, had not given their consent, but they hoped with respect to the latter to overcome any objections. The next objection came from the owners of railways, tramways, and private property. As regarded private property, on the part of the Duke of Bedford and Smith's Trustees objections had been made under a misapprehension, because the company did not propose to take any compulsory powers whatever in respect of private property. As to the railway and other companies, the difficulty reduced itself to a question of the usual protective clause, and he was sure there would be nothing to prevent their framing one in accordance with ordinary precedent. Overlapping powers were asked for as regarded the various electric light companies opposing them, and with respect to the objections raised by the Thames Conservancy and the United Telephone Company, he thought there was a clause in the provisional order giving them what he considered to be ample protection. The company's desire was to give them that protection, and if in any particular they wished the order strengthened, so as to make that provision absolutely secure, the company were willing that it should be granted. As to the South London provisional order, he could only say that the company were anxious to do all they could to meet the wishes of the local authorities and any other bodies who might raise objections. The same might be said in respect of the West London order. The principles involved in the objections raised by the various local authorities and other bodies ought to be summarised under very few heads. First, there was the question of overhead wires. Well, first of all they were satisfied that under the public Act they would have no power to erect those overhead wires, and they did not seek for any powers in the provisional order. But they did not object to introduce the distribution of electricity under section 7 sub-section C of the Act, which provided "that nothing in this order shall authorise the undertakers to place any electric line above ground, along, above, or across the street without the express consent of the local authority." What he assumed on that point was that they could do nothing without the consent of the local authority, to which they had no objection. Another subject of disagreement was as to their capital not being sufficient, and a demand for security. There, again, to prevent repetition, he adopted the argument of his learned friend Mr. Pember, and considered that it was a condition precedent to their getting any powers at all that they should satisfy the Board of Trade as to their financial position. The company did not consider that it should be a question of giving security as one of absolutely satisfying the Board of Trade that they had ability to carry out the works they undertook. Then a question was raised as to the sale of the powers by the undertakers, which the company said they could not do, and which they did not ask for any power to do. But some of the objectors, not all of them, asked that the 42 years should be reduced to 21. There the company and they were absolutely at issue. They considered that the matter was settled by the Act of 1888, before the passing of which full evidence was taken on the subject. The company would make no concession, therefore, on that point. Then the question was raised as to the time within which the supply should be given, and the company proposed 18 months as a reasonable limit. As regarded the area over which they were asking for powers, their view was that they could work more economically and better having a large area, and by means of a company with a large capital, than they could on a smaller scale within more limited districts; and their point of view was that both the local consumers, as well as the company supplying them, would be benefited by the proposal the company now made as regarded area. It was also asked that if subways were made in the future the company should be compelled to place their mains at their own expense in those subways. He could only say that they would be glad to take advantage of subways wherever they existed, but he thought that no obligation should be placed upon them in regard to subways until the question actually arose. If subways were to be constructed, arrangements between the company and the local authority could be easily made, whereas as it was now a premature question. Questions were also raised as to the safety of supply which could hardly be raised with reference to the system which they proposed to adopt, but that was a matter which would be under the control of the Board of Trade. He concluded by referring to a few minor alterations in the orders which were proposed by the company in deference to the views of the local authorities.

Sir John Pender, chairman of the Metropolitan Company, was then called and examined by Mr. Lyttleton. He said that the authorised capital of the company was £500,000, divided into 50,000 shares of £10 each. He believed that 43,900 shares were applied for, and that there were 700 shareholders on the register, and that £3 a share had been called up. At the present time, therefore, £131,700 had been called up; £40,000 of that amount had been spent on the Whitehall station. The Whitehall Company was taken over when it was just starting. The company had since acquired the station at Rathbone-place, and were erecting stations in Sardinia-street, Manchester-square, Ecclestone-place, and at Waterloo Bridge. It had

Digitized by Google

been his special business to deal with the financial side of the business. To establish those stations, the company had spent about £350,000 out of the £500,000, which in his opinion allowed for an ample margin for working capital and for extensions if they were required. If in the future extension became necessary or desirable, he had not the least doubt that they could raise further capital. In fact, he would not consider the company a success if they did not quadruple their present capital. They would have no difficulty in finding the money if the present installation gave the return anticipated. He did not at all object to wholesome competition.

Cross-examined by Mr. W. S. Wright, **Witness** thought that the object of all companies promoting electric lighting should be to make it satisfactory to the public as well as to the shareholders. If there could be any understanding which would facilitate the production of the light quickly and cheaply, the different companies should endeavour to do it. Their great object should be to obtain the cheapest light for the public that they could. The production of electricity was now in such a state that he would not be surprised if at any moment some wonderful discovery was made by which electric lighting would be greatly cheapened. His company were not bound by any system, but promoted that which they believed to be best suited to the locality in which they proposed to establish their business. Speaking as a consumer of electricity, he would prefer that there should be more than one system in a particular district—not, perhaps, if he were an interested shareholder in the company getting the provisional order. Those who did the work best were sure to get the most business. He did not think it likely that three or four companies would go into the same district for commercial reasons. It was his opinion that the Board of Trade should be the judges as to how many companies should be allowed to take possession of one district, so as to prevent the blackmailing of existing undertakings satisfactorily meeting the public demands. There was no limit to their capital powers, and if they found that in the districts they supplied the demand was in excess of what they were able to give in the way of electric light, they would issue debentures to an amount adequate to meet further extensions of their business.

Cross-examined by Mr. Russell Griffiths, he said that the company would ultimately turn their attention to giving motive-power over the area for which they sought their provisional order.

Mr. John Edward Henry Gordon (electrical engineer to the Metropolitan Electrical Supply Company) was next called and examined by Mr. Lyttleton: He deposed that at their Whitehall station they had experienced no difficulty as regarded noise, smoke, or vibration. It was quite possible, by using proper precautions, to get rid of all such difficulties. They intended to adopt the alternating-current transformer system in the scattered districts, and the pressure they would have in their mains would be 1,000 volts. They were making preparations for supplying 50,000 lights in Sardinia-street, and the work was being carried out by the Westinghouse Company. He found that that company had put up 120 or 130 central stations, and desiring to have the fullest benefit from it, they determined to put the lighting in its hands. At Rathbone place they were running 2,000 lights, but they had put in plant for 24,000 lights. They proposed to use the same engines and dynamos as those used at the Whitehall station. The station at Manchester-square would be capable of working 40,000; Willans engines and Elwell-Parker dynamos would be employed. At Eccleston-place, Victoria, they had premises capable of accommodating 150,000 lights, and they were putting in at once machinery sufficient for 40,000. Waterloo wharf would be one of their principal stations with accommodation for supplying a large number of lights. He thought there would be no difficulty there as to smoke or vibration. The Whitehall station was situated near more valuable property than any of the others. The amount that the company was spending on machinery was £195,000, on buildings £50,000, on mains from £80,000 to £100,000, he could not say exactly, to which had to be added the cost of sites, etc. The total amount was about £370,000. They intended to limit their pressure to 1,000 volts—the highest pressure which had been used in his experience was 2,500 volts. It was on the alternating-current system. There was no difficulty in insulation at that pressure. Their mains would be all underground. He proposed to place ordinary gaspipes from three to five inches diameter along the streets, and at every house a junction-box, so that in case it were required instead of having to open distributing-boxes they would simply have to take up one flagstone over the junction-box. At intervals of 200 yards he would place a testing-box, so that should anything have to be done to the mains the person doing the work could open the lid and pull the main through the pipes. At Paddington the chief nuisance arose from clouds of dirty smoke—one man going so far as to say that meat turned sour in his cellar. But the nuisance was absolutely stopped, and he had heard no further complaints.

Cross-examined by Mr. Pember, **Witness** said that the consumption of coal at Paddington never exceeded 100 tons a week. It was about 12 tons a day for 25,000 lights. All their coal would be taken through the streets from the wharves. He denied that there was any noise from the engine-room.

Cross-examined by Mr. Shiress Will, he said that they desired to adopt the experience of all countries.

By Mr. Wallace: They proposed to light only a small portion of St. Margaret's, Westminster. The mains could easily be drawn in and out of the street openings he referred to. It would not be necessary to draw out the whole length of a main in which some connection had gone wrong. Faults could be remedied by cutting the connection at a junction-box on each side, not at the test-boxes, pass a new length of main through, and connect it across before cutting the other, so that the only interruption would be between the two junction-boxes.

Cross-examined by Mr. Muirhead, he said that the alternating-current system could not be used with storage batteries.

By Mr. Russell Griffiths: The whole process of opening a testing-box would take about six hours, and could be done at night. He would place mains 12in. under the pavement, but in a road with heavier traffic it would be desirable to put them deeper. They would have no overhead wires at all. He preferred dynamos of about 200 h.p. each, from which they could get 4,000 lights.

Dr. John Hopkinson, examined by Mr. Lyttleton, observed that this system was adopted at many stations. With respect to uniformity of distributing electricity, it would be much more uniform unless they worked on an exceedingly high potential with few machines. Its great advantage was that as the consumption varied they could vary the number of machines employed during early morning and afternoon. With the Metropolitan Company's plan, it would, he thought, be impossible for the supply to fail in any district. They had carefully considered the question of adopting 10,000 volts or to go to 2,500, and came to the conclusion that, though there were some advantages in adopting the higher potential, they would be counterbalanced by the disadvantages of a possible breakdown in the mains or transformers. He believed that accumulators would run to £30 per horse-power in the maximum amount put in, and they lost 30 per cent. of power.

Cross-examined by Mr. Russell Griffiths, he said that the proper arrangement to prevent disturbance to telegraphic and telephonic wires would be that when there was a current going out there must be one coming back carrying the same current within six inches.

Dr. Fleming, recalled and cross-examined by Mr. Moulton, said that electricity furnished from storage batteries was favourable to the long life of a lamp, but he did not know that there was anything in an alternating current which would of itself shorten the life of a lamp. Assuming that they had constant voltage, the one would not give a longer life than the other.

Cross-examined by Mr. Pember, he added that he had had lamps to live 7,000 to 8,000 hours.

In further reply to Mr. Cripps, he said that the variations in pressure could be made lighter with the Metropolitan system than with batteries, because with the latter they must go by steps in one cell at a time.

Mr. Alfred Henry Walton, examined by Mr. Lyttleton, said he had been manager of the Paddington works since the Great Western took them over. There had been no complaints for two and a half years. There had been a slight alteration in the construction of the machines to get rid of nuisance. The field-magnets which revolve had pole-plates at the extremities, and the fixed coils on the machine were supposed to have one-eighth clearance all round. On one side of the machine they took out the coils, and shortened them on the top sides, so that they gave a quarter of an inch in front at the left-hand side, and a quarter of an inch on the back on the right-hand side. By this means the two sets of coils set up a different note, and so misconstrued one another, and the reduction of noise was found to be considerable. They ran 4,000 lamps of 25 c.p., and about 100 arc lamps from that station.

Mr. Thomas Spencer, examined by Mr. Cripps, said he was the engineer of the Westinghouse Company, and had considerable American experience, which company had adopted, by preference, the transformer system, which the Metropolitan Company were now proposing for London. One thousand volt pressure was adopted for the mains.

Prof. Forbes, examined by Mr. Cripps, said that in his opinion the system proposed by the Metropolitan Company was the best that at present could be adopted. It would preserve a high constancy. The loss in the distributing mains between the feeding points would not exceed ½ per cent. The constancy of pressure was better in high-tension than in a low-tension direct supply. The question of the transformers as to keeping the pressure constant was a point of the greatest importance. A fall could not be allowed of more than 3 to 4 per cent. between the hours of maximum and minimum supply. The wiring of the houses generally took 2 per cent. of this, the transformer itself would take 1½, bringing it to 3½ per cent., leaving usually 1½ to play with in the mains. The Metropolitan Company, however, having only one transformer, lost that 1½ per cent. only once. Their system was also highly economical. The E.P.S. was a very interesting but a very costly system, almost prohibitive from an economical point of view.

MONDAY, APRIL 8.

Prof. George Forbes (recalled) cross-examined by Mr. Moulton, said the Metropolitan Company intended to use the transformer system with 1,000 volts pressure, and his preference would be to have each distributing main connected while in action with only one generating source. He had been asked to examine the cost of batteries in many schemes, but had never had one in his own hands as engineer. He had gone into the question of batteries as a source of distribution very carefully quite lately in connection with the proposed lighting at Paddington by the Vestry, but it seemed prohibitive at present. Of course, there is a storage of energy in the accumulator system which there is not in the direct supply system. He had seen the transformer system in America, but had never seen it put to earth there. He thought to put the secondaries to earth a very good thing indeed, but he objected most positively to putting the primaries to earth. The system he had seen worked at Berlin was the most economical production of electricity for a central station in the world—that is to say, the combination of engines and dynamos with condensing arrangements, etc. There was less fuel used for the electrical unit given out in the central station than he had ever seen anywhere else. The greatest variation of pressure allowed in the mains at Berlin was 1½ per cent., which was, he thought, a proper regulation, but necessitated enormous expenses for mains.

Cross-examined by Mr. Russell Griffiths: He had had experience of the system now worked at Rome and Milan. At Rome it is altogether alternating; high-tension alternating at Milan—a mixture of three different systems. At Rome, the conducting mains are of wire running

Digitized by Google

below the surface. The public and private lighting would be 6,000 or 8,000 lights of 16 c.p., but it is a new thing, and they are putting down engines as rapidly as they can. The public lighting consists of about 20 or 30 lamps. The biggest engine is of 400 h.p. The cost of the lighting is pretty high—considerably higher than that spoken of for London. At Milan they have alternating current used for lighting up two large theatres, they have continuous current on the low tension for most of the incandescent lamps and some arc lamps, and they have also the arc lamp distribution over the whole town, lighting the public streets—high-tension continuous current. Nearly the whole of the arc lamps are used with direct current—either on the low-tension system or on the high-tension system—using the same generating stations, but separate engines and separate dynamos. The station has 14,000 incandescent lamps of 16 c.p., and supplying 350 arc lamps in the streets. The arc lamps were what is called 2 000 c.p.—that is, about 500. They have been using Edison's rigid mains, jointed; but they have introduced largely wire mains. For the arc lamps, however—and only for the arc lamps—they use overhead wires. Coming back to the general question, if they had to light a large house—like Winchester House—with a great number of rooms, it would not be necessary to have more than one transformer under the Metropolitan system in the house. There would be no difficulty whatever with working it with one transformer; but he did not say it would be the best way. He did not like to say what was the greatest load of lamp supply one transformer could safely carry. He did not think any limit had been proved. They had experimented a great deal in America, and the result of their experience was that they do not make transformers larger than 40 lights of 16 candles.

Cross-examined by Mr. Moulton: He had been asked by the Vestry of Paddington to advise them on the subject of electric lighting. The plan which he was proposing that the Paddington Vestry should adopt was to burn their dustbin refuse in properly-designed furnaces to get up steam. The principal difficulty in the way of doing that was that the dust was always coming in during the day, and the burning of it would be all during the night. It was most desirable to get some means of burning the refuse, both day and night, and this was, he might mention, the principal object that made him determine to put down secondary batteries as the first enlargement of the plant, if the plan was gone on with.

Cross-examined by Mr. Wilkins: He did not think any experience had been had with working rigid mains with high-tension current; and to work a rigid main, concentric or otherwise, on a high tension would be an experiment. On the low-tension rigid mains, the joint was always the weak part, and the difficulty of making a secure joint was enormously increased by the tension of the current. He did not think there was any difficulty which could not be got over in connecting the service main with the house from a rigid main, but the chief question was that of insulation. He would not like to make the connection while there was a high-tension current in it.

Examined by Captain Cardew: He would have no objection to putting the secondary to earth in the alternating-current transformers, and he thought it would assist the safe working. If he had absolute control, he thought he could work to a $1\frac{1}{2}$ per cent. variation of pressure. The fact that a concentric main was being used would not increase in any way the danger of making a connection to a house circuit from a distributing main while it was charged; it was not the danger, it was the impossibility. He was aware there were larger transformers in existence than 40-light transformers.

Mr. Alexander Siemens, vice-president of the Institute of Electrical Engineers, was next examined by Mr. Cripps, and deposed that he had had great experience abroad as well as in this country in fixing up electric light installations, including those at Berlin, Moscow, Darmstadt, Munich, and Ebrefeldt. His experience as regarded those cities was that they ran the system now proposed by the Metropolitan Company. In Berlin there were several comparatively small stations, and it was intended to put up a few more, eventually connecting them all in the same way as the existing ones had been connected. In some places there was only one central station where the demand for the light was not very great. The system had been found to work well in Berlin. In St. Petersburg they had a central station with the three-conductor system direct current. In Moscow it was the same. His experience of Darmstadt—they employed a series of batteries in a totally different way from that which was called the E.P.S. system. It was a four-wire system. At Munich it was the three-wire conductor as well as at Eberfeldt. He could not give the exact number of lights there. The pressure through the mains at Berlin was 110 volts. From his experience, considering the condition of London, he was rather inclined to believe that the system in use at Darmstadt, which was a modification of that adopted in Berlin, might best satisfy the wants of London. At the same time, having regard to the long distances, which greatly exceeded those in other places, the transformer system would be as good—that was to say, the transformer system with a number of central stations for generating the current. There would be a saving in cost if they could have the generating centre near the district to be lighted. Five thousand volts was the highest pressure in mains successfully used at Rome. He had made experiments with 10,000 volts. There would be no question of safety in running a pressure of 1,000 volts. If the mains were properly manufactured and laid, there ought to be no leakage.

By Mr. Moulton: In the direct system they could feed into a network at as many points and have as many generating units as they liked, and a constant pressure would be maintained.

Cross-examined by Mr. Shiress Will, **Witness** said that the stations to which he referred were not very far apart—about half a mile. In Berlin they had the two-wire system, which required more copper than the three or four-wire process, which he would not recommend for London. He did not attach much importance to the fact of vibration and noise being a nuisance to the public, because there had been an installation put up and running at the Savoy with 1,200 lights, and nobody had heard it. He did not believe that there had been many complaints made in Berlin.

Cross-examined by Mr. Russell Griffiths, **Witness** said that the object of his experiments with 10,000 volts, which took place at Woolwich, was merely to see what would happen. They had no underground mains to experiment upon. They wanted to see how their machinery would behave in generating such a current.

In reply to Mr. Cripps, he said that if any trouble had been experienced in Berlin it had been overcome.

Sir Wm. Thomson, examined by Mr. A. C. Cripps, said he knew the system which the Metropolitan Company proposed for the supply of electricity to the metropolis—alternating currents and transformers. It was capable, in his opinion, of being used by means of central stations in crowded places. As far as his experience had gone, the highest pressure in vo'ts employed in mains was 2,400—at the Grosvenor Gallery.

Examined by Mr. Graham, he said that he saw the beginning of the works at Deptford, and was familiar with the system by which the London Electric Supply Corporation proposed to bring their electricity to London. It was on the high tension principle. There had been an experience of a pressure up to 2,400 volts. None, so far as he knew, beyond that. He did not think there was an insuperable difficulty in going up to 10,000 volts. It was a very great experiment, being a considerable rise in the voltage, but in dealing with it he thought that electricians had now so much knowledge of the subject, not from practical experience, but from experimental knowledge in the laboratory and from theory, that he did not think there would be any difficulty in going up to 10,000 volts. He did not think there was any insuperable difficulty in properly insulating the mains coming up from Deptford. Any difficulties in laying the mains would, he had no doubt, be successfully overcome. Provided the outer sheath of the mains was well insulated, there would be no leakage to the earth except at Deptford. Provided proper care were exercised by the workmen, there would be no danger to life from such a high potential than there was from a circular saw. For large centra lighting, the reserve power that could be best employed would be to have duplicate engines; for small domestic lighting in isolated places, storage batteries. The direct current was in advance of the alternating current system. He had used it himself in 1881. It was the only one thought of for several years.

Cross-examined by Mr. Moulton: There had no doubt been difficulty in making permanent good joints in underground conductors, but it was not insuperable. Defects in joints did not show themselves at once, but gradually. The seriousness of such defects was, of course, greatly increased by great pressure. In fact, it might be put in this way, that though the circular saw was comparatively safe in the workshop, it was not good in the nursery, and it was exceedingly important to keep high-pressure currents as far away from the consumer as possible. In the direct system, as ordinarily applied, the current was fed at a great number of points into the network. He thought that the best form of reserve power was reserve generating plant. A number of generating units, though not theoretically necessary under practical working conditions, would be of great advantage. For straggling areas there was no doubt that the transformer system was the best.

Cross-examined by Mr. Shiress Will, he said that so far as leakage was concerned the mains could be laid underground as safely as carried overhead. It was a very frequent thing to have two sets of dynamos, one ready to replace the other. He believed that was the system adopted at the Grosvenor Gallery. If the high-voltage dynamos were not well designed, there might be tendency in them to spark.

Cross-examined by Mr. Wallace, he admitted that he had no experience of electric lighting in Germany. He had always been, and was so still, in favour of the direct system with storage batteries for work at a distance. There were advantages in both systems. He took a great interest in the transformer system. He was not practically acquainted with the insulating material to be used for the mains. He had heard it only described. Twelve hours' supply would suffice for a useful storage reserve.

Cross-examined by Mr. Russell Griffiths, he said that he did not anticipate any disturbance to the telegraphic or telephone lines from the high voltage where the outside of the mains was properly insulated. He had not considered what the insulating material should be, but there was no difficulty about that. He thought that an insulation equal to 200 or 300 volts would be amply sufficient for the high-tension mains.

Examined by Captain Cardew, he said that he would recommend the earthing at the Deptford end and earthing of the supply wire in every house one of the two supply low-tension mains in every house.

Re-examined by Mr. Graham, he said that he knew of no difficulty that could not be overcome with proper insulation. His opinion had grown up in favour of the transformer system.

Mr. J. S. Balfour, M.P., a director of the Metropolitan Supply Company, was examined by Mr. Lyttleton, and said that he believed the subscribed capital of the company was sufficient for their present purposes. He thought that there might be extensions of the company's undertaking in the future, in which case there would be no difficulty experienced in raising as much money as might be required to carry them out. He was a considerable owner of property in South London, from which there were a large number of applications for the light. Their original £500,000 capital was over applied for, and there would be no difficulty in getting a million if they wished to raise it.

In reply to Mr. Wallace, he said that the public subscribed their capital on the faith of the companies' getting the provisional order they applied for, which was alluded to in the prospectus. He had not entered into any agreement with the House-to-House Supply Company, nor was it likely that such an agreement would be entered into.

Cross-examined by Mr. Moulton, he said that they had not entered into any agreement with the Strand Board of Works. There had been some negotiations, but nothing definite had been decided on.

(*To be continued.*)

COMPANIES' MEETINGS.

ORIENTAL TELEPHONE COMPANY.

The ninth ordinary annual general meeting of this Company was held on Tuesday at the City Terminus Hotel, Cannon-street, Mr. William Addison in the chair.

The **Chairman** congratulated the shareholders on the position of the Company. Each year they had been doing better. The Directors recommended smaller dividends than might otherwise have been declared for the purpose of enabling them to form a reserve fund, which would be easily realised, if necessary, and enable them to extend the business of the Company without calling upon the shareholders for more money. They proposed to place £2,500 to the reserve fund, to apply £3,000 in final extinction of preliminary expenses, and to write off £341. 4s. 8d. for depreciation of stores and the balance of the cost of the reconstruction of the Rangoon exchange, besides paying a dividend of 3 per cent., free of income tax, on the paid-up capital of the Company other than vendors' shares, and carrying forward £685. 18s. 11d. He proposed the adoption of the report and balance-sheet.

Mr. Cavendish Bentinck seconded.

Mr. Power said he objected, as a large shareholder, to a dividend of 3 per cent. only when 5 per cent. had been earned. He could not see any reason for putting so much to a reserve fund, particularly after waiting for nine years.

The **Chairman** said it was understood in the outset that the Directors would endeavour to carry on the business of the Company without making another call on the shareholders. They wished to extend their business at the most convenient opportunity, and they could not do so unless they had a reserve fund.

The report was adopted, after two "counts," by 18 to 17.

A 3 per cent. dividend was then agreed to, and Mr. Henry Growing and Mr. Thomas Lloyd were re-elected Directors.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the past week amounted to £3,407.

Western and Brazilian Telegraph Company, Limited.—The receipts for the past week, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £2,171.

Personal.—We are requested by Mr. Slater Lewis to state that he has resigned the managing directorship of the Telegraph Manufacturing Company, and that all correspondence intended for him should be addressed to his private house at Helsby, near Warrington.

Indo-European Telegraph Company, Limited.—The report of the Directors of this Company for 1888 states that the Board express deep regret at the retirement from the chair, after an occupancy of 17 years, of Colonel James Holland, and their satisfaction at the acceptance of that office by the present chairman, Mr. J. Herbert Tritton. The Company's revenue from all sources for 1888 amounted to £110,327, as compared with £104,291 for 1887. The expenses were—on commercial and general account, £28,610; on maintenance account, £23,783—total, £52,393, as against £48,621. Deducting the above expenses, taking credit for £2,695, brought over from 1887, and debiting income tax, there remains the sum of £59,284. From this amount £10,000 has been placed to reserve, and that sum, together with £10,625, amount of interim dividend, has to be deducted, leaving a balance of £38,659. The Directors now propose the declaration of a dividend for the last six months of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year, carrying forward £6,784 to the credit of 1889.

PROVISIONAL PATENTS, 1889.

APRIL 8.

5955. **Improved ceiling rose or connector for electrical circuits and for the suspension of electrical fittings.** Edward William Lancaster, Albert Works, Graham-street, Birmingham.

6005. **Improvements in carbon contacts or commutator brushes.** Charles Joseph Van Depoele, 6, Lord-street, Liverpool. (Complete specification.) (Date applied for under Section 103 of the Patents Act, 1883, 7th September, 1888, being date of application in the United States.)

6007. **Improvements in the construction of electric brushes for curative purposes.** Mary McMullin, 8, Quality-court, London.

6013. **Improvements in wire or cable-uncoiling and wire or cable-straining apparatus.** Edgar Howell Rex Evans, 55 and 56, Chancery-lane, London.

6021. **Improvements relating to dynamo-electric machines and electric motors.** Alfred Lyster Shepard, 45, Southampton-buildings, London.

APRIL 9.

6033. **Improvements in the art of transmitting articulated speech by the agency of electricity, without employing pulsatory, undulatory, or vibratory electric currents on the line.** John Absterdam, 52, Chancery-lane, London. (Complete specification.)

6063. **Improvements in and relating to safety-devices for electric circuits.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.) Complete specification.)

6064. **Improvements relating to electro-magnets and to armatures for dynamo-electric machines or electric motors.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.) (Complete specification.)

6065. **Improvements in and relating to electric motors.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.) (Complete specification.)

6078. **Improvements in electric arc lamps.** Ferdinand Auguste Gobert, 3, Deronda-road, Herne Hill, London. (Complete specification.)

6104. **Improvements in the manufacture of filaments for incandescent electric lamps.** Henry Harris Lake, 45, Southampton-buildings, London. (J. B. Tibbits, United States.)

6112. **Improvements in secondary batteries.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, Middlesex. (Wm. Main, United States.) (Complete specification.)

6119. **Improvements in thermo-electric batteries.** James John Shedlock and Richard Mestern, 9, Gracechurch-street, London. (Complete specification.)

APRIL 10.

6171. **Improvements in means for regulating or controlling electric currents.** Charles Richards Heap, 47, Lincoln's-inn-fields, London.

APRIL 11.

6195. **Improved method of and means for constructing globes for incandescence electric lamps.** George Houghton Shepherd, 4, Little Moorfields.

6209. **An improved exciting liquid for use in electric batteries.** Eduard Liebert, 45, Southampton-buildings, London.

APRIL 12.

6231. **Improvements in apparatus for producing electro-magnetic action with small self and mutual induction.** William Edward Ayrton, 2, Upper Phillimore-gardens, John Perry, 10, Penywern-road, London, and Edward Wythe Smith, 66, College-street, Chelsea.

6284. **Improvements in electric cut-outs.** Herbert Napier Prentice, 47, Lincoln's-inn-fields, London.

6285. **Improvements in dynamo electric machines and electric motors.** Herbert Napier Prentice, 47, Lincoln's-inn-fields, London.

6286. **Improvements in secondary batteries.** David Urquhart and William Bates, 11, Victoria-street, Westminster.

APRIL 13.

6332. **Improvements in connection with electric fuses.** William Harding Scott and Laurence, Paris, and Scott, Limited, Gothic Works, King-street, Norwich.

6384. **Improvements in and relating to electric switches.** Albert Augustus Goldston, 4, South-street, Finsbury, London.

SPECIFICATIONS PUBLISHED.

1888.

4626. **Electrolytic production of metals.** Hoepfner. 6d.
4819. **Electro-medical battery.** Johnson. 8d.
4844. **Electric lamps.** Thompson (Garczynski.) 8d.
5640. **Distributing, &c., electricity.** Edmunds. 8d.
5848. **Electrical operations at intervals.** Edmunds. 8d.
6627. **Electric lamp, &c.** Tabourin. 8d.
6836. **Electro-dynamic relay.** Ayrton and others. 6d.
7308. **Electric date, &c., stamp.** Randall. 8d.

NOTES.

Carlsruhe.—This town is to have a central station.

Italian Telegraphs.—The King of Italy has signed a decree providing for the appointment of a Minister of Posts and Telegraphs.

The Telephone in Holland.—The Dutch Minister of Public Works is about to bring forward a measure for the reorganisation of the telephone system in Holland.

Society of Arts.—A paper will be read by Mr. W. H. Preece, F.R.S., on "Secondary Batteries," before the Society of Arts on Wednesday next, May 1, at 8 p.m.

Belgium.—Public tenders will be received up to May 2 for electric light at the railway station at Meirelbeke, and at the central railway works at Gendbrugge, Belgium.

Helsby.—We are informed by the Telegraph Manufacturing Company, Limited, Helsby, that Mr. J. Slater Lewis has resigned his position as managing director, and has no longer any connection with or interest in the company.

Brush Lamps and the Paris Exhibition.—The Anglo-American Brush Corporation have been compelled to withdraw their application for share at the Paris Exhibition, their works being too busy to complete exhibits in time.

"Continued."—The gas companies at Metz and Venice have applied for powers to establish central stations for lighting by electricity. At the end of this month the last remaining gas jets in the Palais Royal, Paris, will be removed.

Brussels.—As will be seen from an advertisement in another column, the Administration Communale of Brussels have decided to invite tenders from English firms for the public city lighting. The tenders are to be sent in before July 1.

Telephone v. Telegraph.—The long-distance telephone is running the telegraph hard already in news items. At the Birmingham election the result was reported in Sheffield by the National Telephone Company, according to the *Sheffield Independent*, seven minutes before the telegraph.

Overhead Wires in New York.—Owing to the removal, by order of the mayor, of the overhead electric wires in New York, Madison and Union squares and the immediate vicinity were left in darkness on Wednesday, the 17th inst. The cutting of telegraph wires and poles has been continued.

Personal.—We are informed that Mr. Swinburne has entered into partnership with the Earl Russell and Mr. H. S. Holt. Messrs. Swinburne and Co. have temporary premises at Teddington, where they will carry on general electrical engineering. Mr. Swinburne's consultation address is 49, Queen's-road, Wimbledon.

Telegraphs between France and China.—The conclusion of the telegraphic contract between France and China on the Tonquin frontier has now been definitely settled. By this arrangement a wire will be laid down between Langson and Langchow, the capital of Kwangsi—50 miles from each other—and direct telegraphic communication will then be established between Saigon and Pekin.

North German Steamers.—The new steamship, "Munchen," built for the North German Lloyd, for service to South America, is fitted with 300 incandescent lamps. These are supplied by two dynamos—one being for reserve—each of 250 amperes and 100 volts, running at 360 revolutions. The dynamos were supplied by Siemens and Halske, and the engines by Daevel and Co., of Kiel.

Paris.—At the meeting of the Municipal Council of Paris, held on the 17th inst., a concession was granted to MM. Nouvelle and Geisenberger for the lighting of a section of the left bank of the Seine. The section extends to the fortification in one direction, and is bounded by the Rues Saint-Jacques and Tombe-Issoire, and the Rues des Saints-Pères, du Cherche-Midi, and des Fourneaux in other directions.

The Northfleet Electric Tramway.—We are pleased to hear that the Series Electrical Traction Syndicate, Limited, have now received from the Board of Trade a certificate that their electrical tramway at Northfleet has passed the Government inspection, and a license to use electricity as the motive power thereon for seven years. The line will in consequence be opened to the public immediately after the Easter holidays.

Tenders for Roumania.—The town of Craïova, Roumania, is to be lighted by electric light, and tenders will be received from the 1st to 13th June next. Tenders must be addressed to the Engineer (Bureau technique) at the Mayor's office, and must be accompanied with a deposit of 5,000 francs. Contractors must specify (1) the system employed, (2) the price per lamp, (3) the number of years for which the concession is asked.

Electric Lighting in the Inner Temple.—The elaborate preparations made some time since for the purpose of illuminating the chambers and offices in the Inner Temple generally with the electric light have now been definitely abandoned, and the extensive excavations made in the Inner Temple-gardens for the reception of the plant and machinery necessary for the purpose are now being filled in, and the gardens will shortly resume their usual appearance.

A Projected New Transatlantic Cable.—Advices from Barcelona state that a syndicate of commercial men has applied for the Government sanction to lay a cable from the coast of Spain to the Spanish Antilles. As there are already in existence cables from Cadiz to the Canary Islands, and from Cienfuegos to Santiago de Cuba, it is proposed to take advantage of these, and to lay new cables to connect the Canaries with Porto-Rico and the latter place with Santiago.

Water Switches.—M. Marcel Deprez has recently patented some new types of resistances and switches for use with high-tension currents, such as for the transmission of force. In these he uses pure water as the connection, and the metals themselves never touching, there is no spark on breaking contact. Pure water is preferred for high-tension currents, acidulated or salt water is only used for currents of low tension and large quantity. The contacts can be made of ordinary iron or lead.

The Telephone Amalgamation.—The arrangements for the proposed telephone amalgamation throughout England have been unexpectedly pulled up by the refusal of the Postmaster-General to consent to the proposal. No transfer of license can be made without his consent, and the telephone companies are therefore at a standstill. The

Digitized by Google

idea that the Government may have to buy up the companies is supposed to be at the bottom of this move, the value of the system, if amalgamated, being greatly increased.

Folkestone.—With reference to the contract for lighting Folkestone by electricity, one of the gas journals remarks that, although the scheme has passed the Council, and has been practically signed and sealed by them, there still remains a difficulty with the gas company, as their agreement with the Corporation does not expire until July, 1890. Unless they are willing to allow the agreement to be cancelled, with fair compensation, Messrs. Crompton's contract, thinks our contemporary, will either have to be delayed or will become invalid.

The C & C Motor.—We understand that Messrs. Gwyne, the eminent engineers, after a careful trial of various motors, have decided to use the C & C motors in connection with their ventilating fans and their new system of ship ventilation. A second order for 50 of these motors, in various sizes, from 3 h.p. downwards, has been given to Messrs. Shippey Bros., the agents for these motors in England. It may also be interesting to know that a large number of these motors will be used in the Paris Exhibition for driving various exhibits.

Electric Power in Russia.—The following communication from a correspondent in Russia has an interest peculiarly its own. Referring to the "Memoires sur l'application d'électro magnétisme au mouvement des machines," our correspondent remarks: ϽТО СОуNНеНІе ООраТNАО На НЕ̄ІО ВНNМаНІе, N еМу ОbІАО ІІреАОсТаВАеНО Вb КӧНNꞁсОерꞁВ МВсТО ꞁраꞁКАаНсКаꞁО N НꞁКо Нера." We are glad to hear of this point in Russian practice, but with regard to the КӧНNꞁсОерꞁВ, we think it is exceedingly likely it has already been attempted in England.

Electricity in Mines.—Incandescent lights now light up the underground workings of the Anaconda Mine, Montana, U.S. They started off with 500 lamps, but more are constantly being added, and soon 1,000 lights will be in use. Candles are a thing of the past in that mine. Electric lights will also be used in the hoisting works, blacksmith shops, and all shops and buildings about the mine. The mining superintendent says the electric lamps are better, cheaper, and safer than candles. The cost of the whole plant, engines and all, is £5,000.

Importations from America.—The importation of American plant continues to increase in rapidity and importance. It may have been noticed that the s.s. "Erin," "Holland," "Umbria," etc., have brought during the last month nearly a hundred cases of electrical goods, consisting of motors, secondary batteries, to the orders of Messrs. Shippey Bros., and various installations throughout the country, while Westinghouse, Thomson-Houston, Woodward Electrical Company, and others, are shipping largely. It seems that the Americans mean to do as large a business in England in electrical apparatus as they do in the States.

Another Claimant.—We notice in our esteemed contemporary, the *Western Electrician* of Chicago, that there is another claimant (Mr. Freeman) to the honour of inventing the incandescent lamp. It would be interesting to know what Mr. Freeman's claims actually are, and in what respect these claims differ from those of Mr. Woodward, whose invention was patented in Canada in 1874, and in the United States in 1876, which invention describes the carbon, and also claims the parallel system of subdivision. It may be here remarked that Mr. Woodward is an Englishman, born at Birmingham; therefore we must still claim this invention for an Englishman, although the patent, we believe, is controlled by the Edison Company of the States.

Electric Communication for Prisoners.—In accordance with the order of quarter session, electric communication has been established between the police office and the five cells reserved for prisoners at the Shire Hall, Chelmsford. In each cell there is the usual electric button, which on being pressed rings a bell in the office. By an arrangement of discs the officer in charge can see from which cell the call comes, and underneath there is a switch to disconnect, if the prisoner be unruly and keep on ringing. The accommodation is, of course, for prisoners who are ill or who want to see the police for any other reason. The appliance has been supplied by Mr. Stapleton, of Chelmsford.

"Calais-Douvres."—It has been decided to call the new mail steamer of the London, Chatham, and Dover Company the "Calais-Douvres," and the old twin-ship of that name will be withdrawn. The new ship is built wholly of steel, and divided into nine watertight compartments, and is designed to be as safe as engineering skill can make her. She is fitted with very powerful engines, and is expected to make the trip from Dover to Calais within the hour. The vessel is being luxuriously fitted up, and will have, in addition to a fine deckhouse and state saloon a number of private cabins. The lighting will be done throughout by incandescent electric lamps, and powerful arc lights will be fitted for embarkation purposes.

Callender's Bitumen Telegraph and Waterproof Company, Limited.—The annual meeting of this company was held at its offices, 101, Leadenhall-street, on Wednesday, April 17, at 12 o'clock, Sir George R. Prescott, Bart., chairman of the Board of Directors, presiding. A most satisfactory report of the year's working was presented, showing a very large increase of business during 1888, and a dividend on the ordinary shares was declared, a substantial sum being also carried forward to the reserve fund. Sir G. R. Prescott and Mr. Henry Drake were re-elected directors, and the proceedings, which were unanimous throughout, terminated with a cordial vote of thanks to the directors and officers of the company.

Electrical Flaw Detector.—The recent accident at Penistone was thought to be due to a defective crank axle, and Major Marindin, in a recent report, mentions a similar case which occurred on the North Staffordshire Railway, when three passengers were injured slightly. The crank pin of the engine failed, and on an examination the fracture showed a very bad old flaw, extending so far into the metal that it left sound only a strip of $\frac{1}{8}$in. in width along the diameter of the pin. Major Marindin points out in justification of the railway companies that it would be quite impossible to detect a flaw inside the axle by any known method of examination, however careful, and he suggests that if such flaws in inaccessible positions could be detected by some electrical contrivance the invention would be a most valuable one.

Celluloid Slide Rules.—Slide rules are now a *sine qua non* to engineers having to undertake long and extensive calculations. A new slide rule of improved construction has been brought out by Messrs. J. Davis and Sons, of Derby, and 118, Newgate-street. The body of the rule

Digitized by Google

is of wood, in which strips of hard white celluloid are inlaid, and on these celluloid strips the scales are engraved, being thus in black lines on a white ground. The advantages claimed are greater accuracy, together with greater clearness of reading; it wears well, and does not become discoloured; and also the markings remain unchanged, or rather without relative change, from variation of temperature. The rule is of the Gravet type, 10in. long, and should prove exceedingly useful to those who use, or who, hereafter, learn to use, the slide rule for their calculations.

Electric Fountains at the Paris Exhibition.—It seems to have been happily decided, says a correspondent of the *Times*, to make the main buildings of the Paris Exhibition permanent structures—namely, the parallel wings, with their graceful domes, and the machinery gallery, which is exactly the size of the Place Vendôme. A large fountain, to be lit up with electricity, is now being arranged on the model of that at South Kensington as improved upon at Barcelona. Another fountain under the Eiffel Tower will fill the void left by its huge compass-like legs. This also will be lit up, but less elaborately. In 1878 the Industrial Exhibition was in the centre, and all the ornamental and amusing parts were grouped round it. This time the refreshment places, concert-rooms, shows, and gardens will be incorporated, as it were, in the exhibition, thus giving it much greater liveliness. Even in the unfinished condition of the opening day a lively idea will be formed of the attractions of this world's fair.

As She is Writ!—As our readers are aware, the Portuguese are nothing if not authoritative. When we wish to obtain really accurate information we should consult the Lisbon press. We don't, but that is probably owing to our insular prejudice. The following ray of intelligence has been shot across the waste of Biscay from the offices of the *Commercio de Portugal*. It arrived in a damaged condition, probably having struck a fog bank on the way. After describing the arrival at Mossamedes of the English steamer "Amberde," commanded by Mr. Robert Gray, our Portuguese contemporary goes on to say that this vessel at once proceeded to carry out the soundings for the new cable of the "Companhia telegranhica Easter-nand Shout Africam (*sic*) Telegraph C.ª" We thought we knew as much as most people about telegraph companies, and yet if it had not been for the happy chance that threw *O Commercio* in our way we should probably have omitted to notice this new organisation. We wonder what it is they "shout?"

The Lineff Electric Tramcar System at Acton.—Before the Acton Local Board, last week, a letter was read from Mr. E. H. Bayley, on behalf of the Lineff Electric Traction Company, stating this company were most anxious to proceed with the work, and the two jobs of doubling the line (which was before the Board) and laying the electric conductor must be done, if at all, at the same time. Some considerable discussion ensued, and in the end it was agreed, on the proposition of Mr. Blake, seconded by Mr. Miller, that a deposit of £500 be demanded from the company, and also that the company pay the legal expenses incurred in obtaining the mandamus against them, and, further, that a fresh plan must be submitted showing exactly what was approved by the Works Committee. The Works Committee had on their list of recommendations that the plans of the West Metropolitan Tramway Company for doubling the line be approved, and that the Lineff Electric Traction Syndicate be allowed to work the tramway by electricity, but before passing their report these recommendations were withdrawn.

Too Late.—It would serve no useful purpose on our part to delay the expression of an opinion as to the immense loss that has been sustained to the historian of cable work by the death of Mr. Newall. The editor of this paper, who, as is well known, was from its first number till October, 1887, connected with another paper in a similar capacity, was very desirous of obtaining Mr. Newall's recollections about the early history of cable work, and had made arrangements with Mr. Newall to do so. Mr. Newall stated that much of the published information was incorrect. Our contemporary, *supposed* to be run for the benefit of the cable companies and cable workers, and largely paid for by the shareholders of the cable companies in order to support their interests, seems to be absolutely ignorant of the value of any information either relating to cable history or cable work. It is allowing the old workers to die off without obtaining the facts relating to the part they played in the work. But, perhaps, the only thing worth doing in connection with cable work is the reporting at length the sayings and doings of those who control the cable system now. That is a happy state of things and easily done.

Electric Light at the Mysore Palace.—"The Maharajah's palace at Mysore," says the *Indian Engineer*, "is soon to be lighted throughout with electric lights. Every room, hall, nook, and corner will be adorned with these lamps. The first storey of the palace will contain 62 lamps, and the second 120. They are all said to be incandescent lamps of 16 c.p. each, with shade over and a small globe underneath. The palace will be also lit with six arc lamps of 2,000 c.p. each, while at the very top of the palace will be the largest projector lamp in India, of 5,000 c.p., which is intended to throw a light from 60 to 80 miles distance, and throw a shadow which, if thrown up, will be seen at Madras, Ootacamund, etc. The working will be arranged with a current from 53 accumulators, which will be charged by the machines, for which the engine will work once for a certain number of hours every alternate day. The wires have been placed all over the palace with much ingenuity and skill by Mr. Charrington, the electrical engineer, and his assistant, Mr. George Hardaker. The arrangement of lighting by electricity has been calculated to be a saving to the exchequer."

The Electro-Harmonic Society.—The last smoking concert of the season takes place to-night (Friday) at the St. James' Hall Restaurant (banquet-room) at 8 o'clock, when the following programme will be carried out: Part I. Terzetto, "Che fate qui, Signor!" (*Faust*) (Gounod), Mr. William Nicholl, Mr. Arthur Thompson, and Mr. B. H. Grove; violin duet, "Symphonie Concertante" (C. Dancla), M. Greebe and Mr. T. E. Gatehouse; song, "Venetian Song" (Tosti), Mr. William Nicholl; solo pianoforte, Mr. Alfred Izard; song, "Vulcan's Song" (Gounod), Mr. B. H. Grove; solo violin, "Fantaisie Caprice" (Vieuxtemps), Mr. T. E. Gatehouse; musical sketch, "A Children's Party," Mr. Dudley Causton. Part II: Duet, "Sui campo della gloria" (Donizetti), Mr. W. Nicholl and Mr. B. H. Grove; songs, "To Chloe" and "Maiden Mine" (Sterndale Bennett), Mr. Arthur Thompson; violin duet, "Introduction and Rondo" (Kalliwoda) (by desire), M. Greebe and Mr. T. E. Gatehouse; song, "Kathleen Mavourneen" (Crouch), Mr. William Nicholl; trio, "Winds gently whisper" (Whittaker), Mr. W. Nicholl, Mr. A. Thompson,

Digitized by Google

and Mr. B. H. Grove; musical sketch, "Penny Reading Oddities," Mr. Dudley Causton.

Electric Tanning.—Not content with the treatment of sewage, electrical engineers ever seek "fresh woods and pastures new," if we may so describe such unsavoury manufactures. This time it is the tanning of leather hides, the objectionable nature of which is not much less than that of the first-mentioned process. The process of electrical tanning (Worms and Balé's patent, No. 9,515, 1887) appears to have been carried on for some six months at full work in France by the Société Française de Tannage, who turn out leather of the best quality. Some special harness for the Paris Exhibition is to be made of leather so treated. The process consists of subjecting the hides in contact with ordinary tanning materials (without acids) to the action of a current of electricity on a revolving drum. The saving in time is very great—two to four days instead of three to nine months—while the cost is reduced to 1¾d. or 2d. instead of 4d. A company under the name of the British Tanning Company, Limited, 17, Basinghall-street, has been formed to work the process in this country, of which several prominent tanners and Mr. William Crookes, F.R.S., are directors. The process, as carried on in France, has been favourably reported on by practical leather tanners and by Prof. Silvanus Thompson, who found the electrical arrangement well conceived and carried out in a practical manner.

Congress of Applied Mechanics at Paris.—There will be held at Paris, at the Conservatoire des Arts et Métiers, an International Congress of Applied Mechanics, under the patronage of a Committee of Honour, comprising savants and engineers of renown both from France and from other countries, who will give the work of the congress the benefit of their influence and the weight of their authorities. The President of the Committee on Organisation is Mr. Phillips, ex-inspector general of mines (retired). The five members appointed from the United States are, in the order of their mention on the official bulletin, Messrs. Robert Grimshaw (president Polytechnic Section Am. Institute, N.Y.), R. H. Thurston (director, Sibley College of Cornell University, Ithaca), Prof. Egleston (Columbia College School of Mines, N.Y.), and the Presidents of the American Societies of Civil and of Mechanical Engineers. At this congress, among the important subjects submitted for discussion are the unification of the horse-power, the choice of materials in machine construction, the mechanical production and utilisation of artificial cold, transmission to a distance, and distribution of work, by other means than electricity (water, air, steam cables, etc.), automatic cut-off engines with several successive cylinders; thermo-motors other than the steam-engine. Other topics, treated by papers, will be improvements in steam-engines since 1878, progress among associations of owners of steam appliances, and improvements in apparatus for the generation of steam, more particularly sectional boilers.

A New Motor.—We are indebted for the following to our excellent contemporary, *Industries*: "'Sir,—We have pleasure in informing you that we have succeeded in constructing an alternating-current electric motor which, especially in point of efficiency, is in no way inferior to the most perfect continuous-current motors. The enclosure contains particulars of this motor and the experiments made with it, and we place it at your disposal for publication in your esteemed journal.—Yours, etc., GANZ & Co., Budapest, April 10, 1889.'

[The enclosure to which Messrs. Ganz and Co. refer in the above letter does not contain a technical description of the motor, but merely some general remarks on the importance of utilising alternate currents for the production of motive power, coupled with a statement that hitherto this problem has not received a solution. As far as may be judged from the general tone of their remarks, it would appear that in their new motor the armature is at rest, and only one circuit is required. They give the following table of results obtained with an experimental motor which having been worked at a slower speed than that for which it had been designed (750 revolutions per minute), is expected to give when running at full speed even a higher efficiency than that obtained in the trials:

Revs. per minute.	Power developed.		Energy apparently supplied. Watts.	Actual energy supplied.		Ratio between apparent and actual energy.	Commercial efficiency per cent.
	H.P.	Watts.		H.P.	Watts.		
600	15·0	11,000	18,000	21·5	15,800	·88	77·0
700	19·8	14,600	24,200	25·2	18,600	·77	78·5
730	30·7	22,400	29,800	37·6	27,700	·92	80·9

The subject of an alternate current motor requiring one circuit only, capable of starting under a load, and having a fairly high efficiency, is of so much importance to the electrical industries generally, that we make no apology for placing the statements emanating from the Budapest firm before our readers as they were made to us.—ED. *Industries*.]"

The Distribution of Power by Electricity.—The new American journal *Electric Power*, which we have already welcomed into the ranks of technical papers, sounds the note which we have continuously advocated with regard to the distribution of power. It says: "It is useless to attempt to disguise the fact that a large proportion of the local electric lighting companies in the United States fail to return a sufficient margin of profit to entitle them to recognition as first-class business investments. There are various causes for the existence of this state of affairs. Some of the earlier companies were loaded down with the burden of expensive plants, others were handicapped with wasteful or unreliable apparatus. Many have been the victims of mismanagement by the installation of favourite sons as prime movers. Of late years, competition has tended toward the cutting of rates, and has not as yet reached that culminating point where the lamb has lain down inside of the lion. It is well understood that the business of arc lighting soon reaches its limit. Its field is of slow growth, and increased earnings must be sought either in incandescent lighting or the supply of power. Intelligent managers are rapidly being convinced that the power business should not be neglected, and are turning their attention to its eventual development. The obstacle in most instances appears to be that arc systems being most generally used, they are not deemed available for power purposes on account of the danger attending the handling of motors by inexperienced persons. It is perfectly practicable to guard against accidents, provided a competent engineer supervises the installation. The distribution of power, however, is not equally available as a source of revenue in every town, while light from some source is an absolute necessity wherever human beings congregate. What is needed is continual study of the various conditions. Every person should make it a

Digitized by Google

point to note every possible opportunity where electric power can be successfully applied. It must always be borne in mind, however, that if a contract is undertaken, the work must be so done that it will reflect credit on the general interests of the business."

Changes in Copper Wires.—In an abstract given in the *Journal* of the Institution of Electrical Engineers of a paper by M. F. Larroque, on the "Permanent Changes Produced in Copper Wires by the Passage of a Current," in *La Lumière Electrique*, we note the following: "It has been noticed since a long time that the continued passage of a current of electricity in a copper wire tends to render it brittle. Dufour noticed a decrease of more than 30 per cent. in the tensile strength of a copper wire which was traversed by a current insufficient to heat it sensibly. Wertheim thought that he had found that the decrease in the tensile strength was only temporary, and disappeared when the current was interrupted. Edlund and Streintz speak of a permanent elongation, but the experiments of Blondlot have demonstrated that this is an error. So long as the small currents chiefly used in telegraphy were the only ones to be considered, their effect on their conductors was not of practical importance; but with the spread of the sphere of electricity for lighting and transmission of power, and the more general use of heavy currents for these purposes, the permanent effects produced by them in copper wires claim attention. The breaking of an old electric light cable led the author to investigate the question. A piece of a wire used during twenty years to convey the current to a lighthouse could be easily broken up with a hammer; the broken surfaces showed clearly that the metal had a granular structure, such as is seen in copper deposited electrolytically, although when first put up the wire had been hard-drawn. Owing to the section of the conductor, it probably became somewhat heated by the passage of the normal current, though the rise of temperature could scarcely have exceeded 30deg. or 40deg. It seems that the long-continued passage of a current of electricity tends to bring about a molecular rearrangement, resulting in a granular structure. Moreover, as far as experience goes, it seems to be immaterial whether the current is direct or alternating, as the action of both is similar. The secondary of an induction-coil had become so brittle from long use that the wire could not be unwound, but broke repeatedly. The ratio of the resistance of the old wire to that of a new wire of similar length and diameter was found to be as 21 to 16. From his own experiments, which were carried out with spirals and zigzags of copper strip, the author concludes—(1) That the elongations referred to are excessively small, and do not follow any definite law. The lengthenings and shortenings probably result from want of homogeneity, and are not permanent results produced by the passage of the current. (2) That the changes in the tensile strength depend on the strength of the current traversing the conductors, but the relation is not one of simple proportion; the passage of the current has more effect on hard-drawn copper than on annealed copper; alternating currents seem to act more quickly than direct currents. (3) A current of two amperes, especially when alternating, materially changed the elasticity of a copper wire 3mm. in diameter, after a lapse of four years. It would certainly seem, therefore, that conductors carrying heavy currents such as are used in electric lighting are fated to undergo a kind of slow disintegration which will affect not only their tensile strength, but also their resistance."

A Telegraph which Produces a Printed Sheet. The tape telegraph or "ticker" now so common at clubs and brokers' offices is practically doomed, and "flimsy"—the written messages sent out from the telegraphic news offices—is likewise soon to be a thing of the past, by reason of the practical introduction on a large scale of the new type-writing telegraph of Messrs. Moore and Wright in the offices of the Central News Agency at Ludgate-hill. This instrument has been practically tested for some little time past, and we had recently an opportunity of inspecting the instrument at work, and of ascertaining what is its scope, and what is intended to be done with it. The instrument, indeed, fulfils a "long-felt want." The origin of the invention has been, as a matter of fact, the constant complaint from newspaper men of the difficulty of dealing quickly and easily with the news as now delivered. Either it comes in strips, which have to be cut up and pasted together; or it comes in "flimsy," and is liable to tear and smudge when sent up to the compositors. Messrs. Moore and Wright, who are connected with the Central News Agency, therefore, some eighteen months ago started to construct a telegraph which would print its message in lines on a sheet instead of a strip. This instrument they have perfected, and are intending to fit them up in the offices of their subscribers—the newspapers and clubs of London—to the number of some 220, as soon as they can be got ready. The instrument is in reality an electric typewriter, but having one keyboard and any number of sets of typewriters. The keyboard, at present, is arranged like an A B C telegraph, but it has only to be fitted with a keyboard similar to the ordinary typewriter for anyone used to the latter instrument to be able to work the transmitter. The receiver has a type-wheel, controlled by an electromagnet in the same way as the usual tape telegraph, but at every letter the type-wheel is pushed one space along the shaft. The motion of the type-wheel is actuated by a train of wheels, and a second magnet and train of wheels can be brought into play at the end of the line, which causes in one motion the paper to be pushed up and the type-wheel to go back to the beginning of the line. The appearance of the message, printed on a broad coil of paper, is exactly similar to that of an ordinary type-written message, and is, therefore, of great superiority to the tape for news items, or notices for exhibition in clubs, while quotations for stocks and shares can thus be printed in columns for use at once. The receiver is quite as ingenious as the transmitter. A small electromotor revolves, by means of a lightly-resting friction-wheel, a reversing electric contact. This keeps the magnet of the receiver constantly vibrating. As the button belonging to each letter or sign is depressed, this revolving contact is stopped at the letter, and the type, at the receiver end, is struck on the paper. At the end of the line a slightly stronger current is sent by momentarily cutting out a resistance, and then by another button the circuit is opened. The result of the first is to excite the auxiliary magnet of the receiver, which attracts a catch on a pinion, while opening the circuit releases the catch. The second train of wheels comes into operation, shifting the paper and the type-wheel at the same time to begin a new line. The receiver costs about £19, but it is not intended to sell them, but to hire them out in the usual manner as with tape instruments. The Central News Agency will put down a gas-engine and accumulator to work the series of instruments from Ludgate-hill, and it is expected that they will be ready to work about August.

Digitized by Google

MAQUAIRE'S "ALPHA" ARC LAMP.

It will be remembered that at Prof. Silvanus Thompson's lecture at the Society of Arts special mention was made of a new arc lamp, exhibited then for the first time publicly in England, in which the feeding of the carbons was actuated by the motion of a small reversing electric motor in the mechanism. This was Maquaire's patent "Alpha" arc lamp, which, in distinction to other types, was classed under the head of the "electrical engineers lamp." Both the detent action and the mechanical motion of feed are controlled electrically, and the feeding is thus directly dependent of the needs of the lamps, the carbons being fed by imperceptible movements, and only when the electrical requirements of the arc itself need the feeding. The running of this lamp is certainly remarkably steady, and it has very good claims to become one of the leading arc lamps of the future.

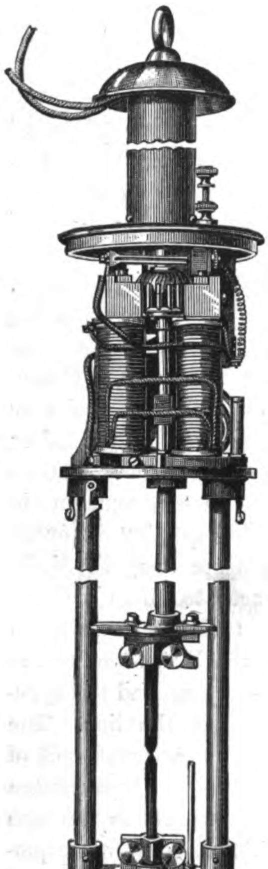

Fig. 1.

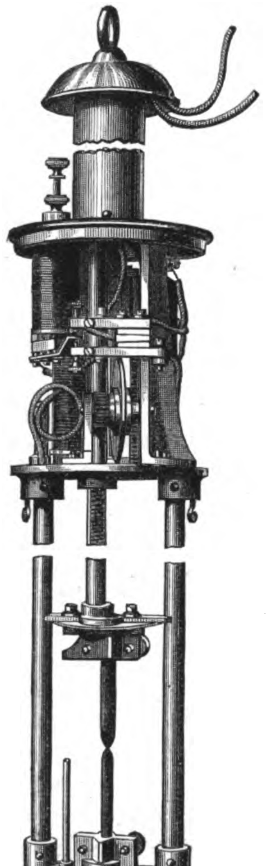

Fig. 2.

We are now able to give illustrations and description of this lamp, from which it will be seen that the new conditions have been worked out with considerable ingenuity. Fig. 1 is the "Alpha" arc lamp with casing removed, showing the small electromotor and brushes. Fig. 2 shows the regulating mechanism. Fig. 3 is a diagram of the connections.

To understand exactly the action of the lamp, we may follow the course of the current through the mechanism. First of all, it may be stated that there is a worm on the motor-shaft, gearing to the rod which carries the upper carbon. When the motor turns one way, therefore, the carbon is lowered, and it is raised if the motor is reversed; this action is, moreover, of considerable force, requiring a strong effort to stop it by the hand, and such minor obstructions as a little dirt, rust, or roughness, often so troublesome in lamps actuated by gravity, are of very little consequence when there is the force of the dynamo itself behind the motor.

The coils, it has been suggested, may be divided into "brains" and "muscles." The coil I is a shunt across the arc, and acts as the brains or directive force, without itself doing the work. The field-magnets and armature of the electromotor are the muscles which, under direction of the brains, move the carbons. On entering the lamp the current first traverses the series coils of the electric motor, then going to the upper carbon and across the arc to the lower carbon, and so back to the main wire. At the carbons, however, a shunt wire leads to the contact, Q, and to the shunt coil, I. The little motor is wound so that its armature is a shunt to the field-magnet, but is so arranged that it is a shunt to either the coil H or the coil H^1 according to the contact made by the vibrating arm, M.

The shunt wire is shown in the diagram by dotted lines. The wire of this shunt circuit is bared at the crossing between the coils, and is connected at this point to the brush, G, of the armature of the little motor; the other brush being connected to the vibrating contact, M, which, under action of the coil, can connect either with N upwards or O downwards. O^1 is an insulating stud. The pull of the coil I upon J is regulated by a screw, L, acting upon the core of this coil.

It will be easily seen that when the coil I acts upon the piece of iron, J, the shunt current is sent through the armature of the motor in one direction, while if it releases it, letting M touch at N, the current will be in the reverse direction. In any electric motor, to reverse the current in the armature, while the current in the field remains the same, is to reverse the rotation of the motor, and this action of the coil I upon the vibrating contact M keeps the motor almost constantly in motion one

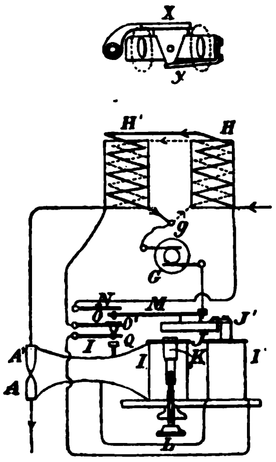

Fig. 3.

way or the other. When the arc becomes long, its resistance increases and more current goes through the shunt-coil, I; this moves lever M, sending a slight current through the motor armature, which feeds the carbons downwards by almost imperceptible motions. Should the arc from any cause increase to too great an extent, the shunt-coil pulls strongly on the lever, M, causing it to press together, by means of the insulating stud, O^1, the contact points P, Q; this short-circuits the arc through the other coil I^1, thereby increasing the pull on the lever, and ensuring good contact between P and Q.

The lamp may be made to strike any desired length of arc and feed at any potential by altering the position of the contacts N and O. The potential on the armature of the motor is two volts.

The arrangement for starting the lamp and striking the arc are shown in plan at the top of the diagram, and can also be seen at the base of the lamp in the other illustration. The lower extremity of the armature-shaft is pivotted at its lower end in a movable V-shaped yoke, X. This, when the lamp is working, is attracted by the field-magnets completing their magnetic circuit, and at the same time throwing the worm into gear with the wheel, which raises the carbons and strikes the arc. When the lamp is not working, the movable yoke is pushed back by a spring, Y; the worm being thus released from the wheel, the rack falls, and the carbons come together.

The burning of these lamps is extremely regular; it is hardly too much to say that not the slightest flicker is ever noticeable to the eye.

Lamps of this description have been burning for some time past in Kensington High-street, near the Albert Hall,

Digitized by Google

run two in series on the 100 volt incandescent circuit, and have given every satisfaction; and it is understood that there are some hundreds of them in the Paris Exhibition.

These lamps, which are also made focussing or double carbon, are constructed by the Planet Electrical Engineering Company, Limited, Victoria Mansions, 28, Victoria-street, Westminster.

PECULIARITIES OBSERVED IN TESTING MATERIALS.*

BY W. CLELAND, B.SC.

(Concluded from page 312.)

Before considering the curves for stress and strain I may mention some experiments of Bauschinger "On the Alteration of the Elastic Limit in Iron and Steel." The extract is taken from *Engineering*, Nov. 25th, 1887:

"An interesting series of experiments on the alteration of the elastic limit of iron and steel, which have now extended over several years, have been made by Prof. Bauschinger, at the laboratory of the Technical School, Munich, and some interesting and important results have been obtained. Most of the experiments were made on one of Werder's testing machines, the deformations being read by Prof. Bauschinger's mirror apparatus, but for the experiments on the endurance of bars a Wohler machine. In the course of these experiments it was discovered that the breaking down point (yield point), had no connection with the elastic limit; thus, when a series of gradually

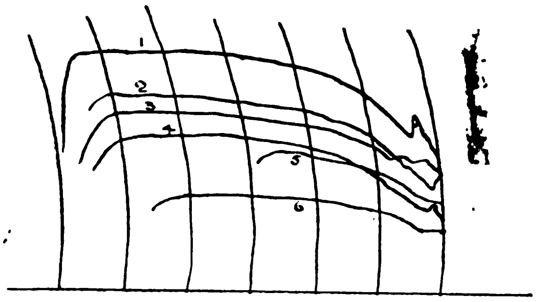

Fig. 10.—Curves showing Variation at Breaking-down Point (Kennedy). 1. Swedish Iron. 2. Shelton Bar Iron. 3. Swedish Iron. 4. Landore Rivet Steel. 5. Cast Steel. 6. Landore Plate.

increasing stresses exceeding that corresponding to the original breaking down point (yield point) of the material were applied to the bar, this point rose with the stress and this rise was continued for weeks and months, and possibly years, if the bar was left at rest under the greatest of these loads On the other hand, when a bar was subjected to an increasing stress greater than that corresponding to the elastic limit of the material, but less than the stress at the breaking down point (yield point), the elastic limit and elastic modulus both increased, but reached a maximum as the breaking down point (yield point), was approached, and then rapidly decreased, the former at times even reaching the value zero. If, however, the bar is left at rest under a stress exceeding that of the primitive breaking down point, the elastic limit and elastic modulus increase again, and the former may attain a point far above its original value. Moreover, the elastic limit in tension is in general very different from that of the material when subjected to compression, and artificially raising the elastic limit in tension as described above caused the elastic limit in compression to be decreased, and this may even pass through the point of zero stress. In other words, a bar of steel or iron has two elastic limits, and whatever position these occupy on the scale of loads, the range between them is nearly a constant quantity. By alternately stressing a bar in tension and compression just beyond the elastic limits, these, after a certain number of repetitions, occupied positions equally distinct from the point of zero load, and the limits thus obtained are called by Bauschinger the natural elastic limits of the bar. It was then noted that the stress corresponding to these limits sensibly coincided with that found by Wohler as the limiting stress to which a bar could be subjected to alternate tension and compression. It would thus appear that a bar will bear an indefinite number of repetitions of stress, provided the range of stress does not exceed the elastic range mentioned above."

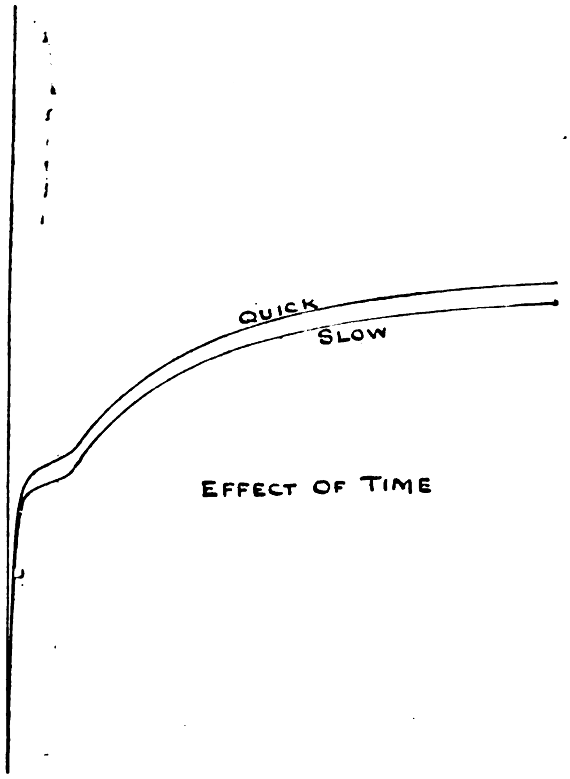

Fig. 11.

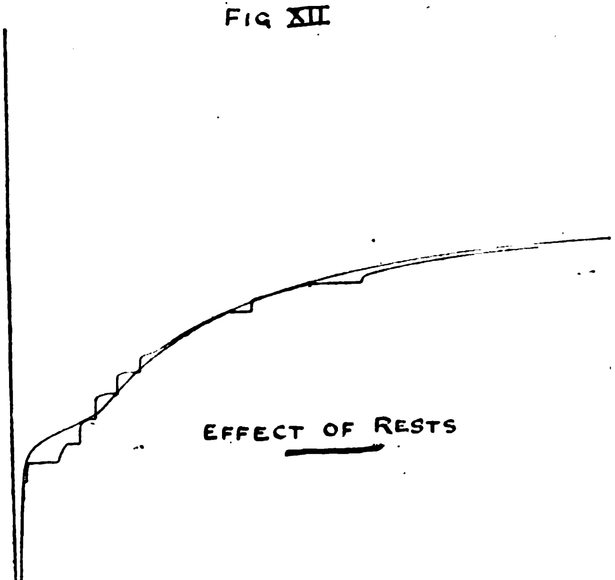
We have so far discussed the external features presented by metals when under test; but we gather far more information from a study of the curves connecting stress and strain. The life history of the specimen is written there so plainly that those who run may read. In Fig. 4 I have drawn an exaggerated form of the curve, in order that the

Fig XII



characteristic features may be seen more distinctly. A, B, C, D, E, F represents the curve as got from iron or steel, as regards the distinguishing points. For copper or brass, the part B, C, D of the curve is absent, and even with steel in certain conditions. From A to B the curve is a straight line showing the proportionality of stress and strain, or Hooke's law. B is called the elastic limit, and

* Paper read before the Physical Society, Glasgow.

Digitized by Google

beyond this point the stretching increases till we reach C, when the material yields to the stress or breaks down. This point, C, is called the breaking down point, or yield point. The stress now becomes smaller, while the strain increases until we reach D, where the specimen seems to recover itself, the stress now increasing along with the strain. At E we have attained the maximum stress, and local contraction sets in. At this point we have an action similar to what takes place at C—that is, the strain increasing while the stress is diminishing until F is reached, when the specimen breaks. I have given along with this paper some curves for iron, brass, copper, and indiarubber, drawn by Prof. Barr's wire testing machine. Some of the points mentioned above are not seen in the curves. For example, the part of the curve for iron beyond the breaking point does not show any hollow, and in neither the iron, brass, or copper is there any trace of local contraction. This is a defect in the apparatus. There is no arrangement made to allow of the reduction of stress. We have made experiments to try to remedy this, but up to the present these have been unsuccessful. The

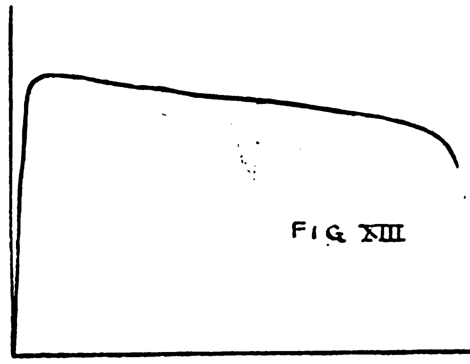


FIG. XIII

Zinc Curves.

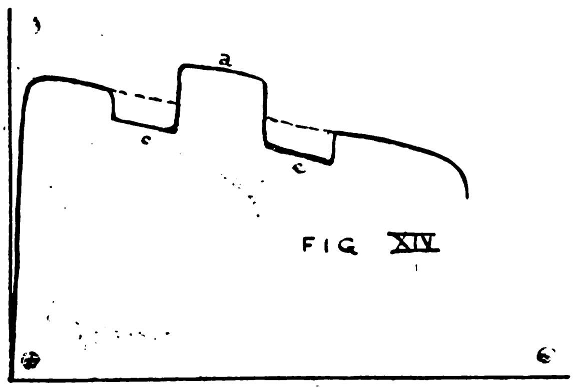

FIG. XIV

elastic limit in the case of copper and brass is well marked in the curves, but no such point can be observed in the curve for indiarubber. It has rather a peculiar history: altogether apart from that of metals. The stress and strain at first increase almost uniformly up to a certain load; after this the strain is very much greater than the stress. But towards the end of the curve the state of matters is reversed; the strain now becomes almost nil, while the stress increases very rapidly. This is experienced when we attempt to stretch an indiarubber band. At a certain point the indiarubber becomes almost as rigid as metal. I think, however, that the most peculiar point about these curves is the form of the curve at the yield point. It seems due to some artificially created restraint of the particles, which at this point suddenly breaks down; but if this were the case, annealing should have the effect of abolishing this point. Fig. 9, taken from Prof. Unwin's book on "Testing of Materials of Construction," shows the effect of annealing and hardening manganese steel bars. It rather leads one to the belief that the particles of a body are brought to their natural state through hardening. This disappearance of the yield point is not a characteristic of manganese steel bars only; it has been noticed in some hard steel used for rails. I have copied some diagrams of Prof. Kennedy's to show how the yield point varies with different materials. It has been stated that since at this point extension takes place very rapidly, the peculiarity may be due to inertia; but, in the autographic apparatus used for the above curves, the effect of the inertia of the load is eliminated. Time is another reason which has been given. In the curves given in Fig. 11 showing the connection between testing two specimens of wire from the same coil, we see the difference at the breaking down point. It is assumed that if the rate of test were slow enough, the bend in the curve at the breaking down point would get smaller and smaller, so that the result would be after this form. The curves are drawn after the shape of those got from Prof. Barr's machine. The thick line indicates the assumed last form of the curve with the test very slow.

In a previous part of this paper I have spoken of the effect of raising the elastic limit by stress. In Fig. 12 we have a diagram showing the point very clearly. When the curve has reached the point A, the load is taken off and the pen traces the line, A B. When started again, the pen goes back along the same line to A; but instead of taking up the curve of this point, it goes beyond it to point C. This point constitutes a second breaking down point. Beyond C a line, almost horizontal, is drawn until what would have been the continuation of the old curve is reached. It is seen that the same effect takes place at any other point on the curve. These points constitute new elastic limits, and are all greater than the primitive elastic limit. In Fig. 13 we have a similar result. The diagram is to show the effect of rests, and the result is strange indeed. Instead of describing a curve as one would have imagined, a line, almost vertical, is traced, when once the test is proceeded with again, and breaking down points experienced similar to those in the last figure.

I will close this paper with two diagrams given by Mr. Martens. They are both for sheet zinc, and the second one shows very clearly the result of changing the rate of test. He says, "with sheet zinc he had obtained diagrams with his diagram apparatus, which usually had the form shown in Fig. 13 when the work was done with uniform velocity. If, however, during the experiment the velocity of extension was changed, the diagram had somewhat the appearance given in Fig. 14; with a low velocity the distance, *c* and *e*, with high velocity, *d*, was traversed. It was easy to obtain differences in the force ordinates, which amounted to more than one-third of the maximum heights. In a similar way, he was able to prove that with steel a diminution of resistance of about 1·3 per cent. was effected by slow operation, under by no means exaggerated conditions."

LITERATURE.

The Telephone. By W. H. PREECE, F.R.S., and JULIUS MAIER, Ph.D. London: Whittaker and Co., 1889.

"'Tis as great a fault to judge ill as to write ill, and a more dangerous one to the publick." So said a writer whose name is celebrated in English literature, whose works are to be found in every respectable library, but whose genius is unappreciated by the present generation. Another great writer, still living among us, speaking of the historian Buckle, says, "Every man, so Buckle said, acted from a motive, and his conduct was determined by the motive which affected him most powerfully. Every man naturally desires what he supposes to be good for him; but to do well he must know well." If Buckle's contention be true, then every man who writes a book does so from an all-powerful motive. It is not necessary that the motive should always be a pecuniary one, and we are fain to hope that while this may play its part the writers of technical books have something higher and nobler as the mainspring of their labours. Be that as it may, "to do well" requires "to know well." A man full of his subject pours it forth without appreciable effort, while the man who knows less trips very haltingly. There is a class of book very important in its way, however, which hardly falls within the category of those that require to know in order to do. And to this class we consider the book before us belongs. In thus judging we have in mind the dictum given in the first sentence above. Our conclusion is based upon the fact that the work seems rather that of a compiler and abridger than of an author. It gathers together the fragmentary history of the

Digitized by Google

development of telephony as found scattered through various ephemeral publications of the past ten years. Here, then, we have given in a consecutive, compendious form the history of and existing practice in telephony, linked together by short essays of a more theoretic character. Such a book would neither make nor mar an author's literary reputation, but it would indicate, when well done, a careful, painstaking investigator. According to our views and classification, this book is well done, and shows that the authors have made a most extensive, even if it be not absolutely exhaustive, examination of the current literature on the subject. We find brief references to early writers on transmission of sounds and speech to a distance, till the work of Bell, Edison, and Hughes gave the telephone a practical form. The theory of the subject is dealt with in a short and simple manner, and the bulk of the book consists in the description of apparatus and systems employed in various parts of the world, together with statistics on the subject. All this is extremely interesting, but hardly calls for criticism. There can be no differences of opinion as to the value of a clear description of Brooks, the Pattersen, the Post Office, the Felten and Guilleaume, or any other underground cable. We are glad to see and must congratulate the authors on their cosmopolitism. Telephony does not owe much to England, nor can our factories vie with those of the Western Manufacturing Company in the production of apparatus. No doubt we copy the types of apparatus produced by other manufacturers, and after giving them a distinctive colour, appropriate them as our own design. Such a book as this will assist in determining the progenitor of instrument or system. There is one feature against which we must protest. If publishers will use borrowed blocks for illustrations, for goodness sake anglicise French blocks in English books. Take as an example, Fig. 172, p. 364. In the text we rightly get "central office," in the figure *bureau central*. In the figure you get *signe d'abonné*, *poste d'abonné*. You get reference letters not mentioned in the text, and so on. This is annoying, to say the least, and ought not to be tolerated in a book of any pretensions. We have almost said our say. The book should be in the hands of every man and woman whose livelihood depends upon telephonic work, for none ought to be so engaged without desiring an appreciative knowledge of the subject such as they may here obtain to perfection.

OBITUARY NOTICES.

WARREN DE LA RUE.

We regret to announce the death of Mr. Warren de la Rue, D.C.L., F.R.S., Ph.D., which occurred on Good Friday. He was the son of the late Mr. Thomas de la Rue, and was born in Guernsey in the year 1815. He was educated at the college of St. Barbe, Paris, and succeeded his father as head of the firm of Thomas de la Rue and Co., from which he retired in 1880. In the course of his conduct of the firm, Mr. de la Rue applied his scientific knowledge to purposes of practical utility, and patented a number of inventions, among them being processes for utilising earth oils, and machinery for simplifying the making of writing materials. The principal scientific work in which he distinguished himself was the application of photography to the recording of celestial phenomena. The photographs, when measured by a micrometer which he invented, furnished exact astronomical data. In 1860 he went to Spain with the Himalaya Expedition, and was successful in obtaining a series of photographs of the total eclipse of the sun on July 18. The results formed the subject of the Bakerian lecture delivered to the Royal Society in April, 1862. In conjunction with Prof. Balfour Stewart and Mr. B. Lowry, he published "Researches in Solar Physics," founded on observations made at the Kew Observatory under his directions. He also took an active part in making the preparations for the photographic observation of the transit of Venus in 1874. He established a private observatory at Cranford, Middlesex, but it was dismantled in 1873, and the instruments presented to the University of Oxford, where they have been employed most successfully by Prof. Pritchard in determining, by means of photography, the distance of 61 Cygni and other fixed stars. In 1874 he fitted up a private physical laboratory, where, employing a battery of 15,000 chloride of silver cells, he has, in conjunction with his friend, Dr. Hugo Müller, carried on an elaborate series of researches on the electrical discharge. The results of the researches have been from time to time communicated to the Royal Society and the Académie des Sciences, Paris. "The Phenomena of the Electric Discharge" was also made the subject of a most interesting lecture, illustrated by a great number of experiments, at the Royal Institution in 1881. Nearly all the results of Dr. de la Rue's scientific work have been embodied in papers and memoirs, which will be found in the *Transactions* of the Royal Astronomical, Chemical, and other learned societies. He acted as juror and reporter in the Department of Class XXIX. in the Great Exhibition of 1851, was a juror in Class X. of the Paris Exhibition of 1855, and presided over Section B, Class XXVIII., of the Exhibition of 1862. He was a member of the International Electrical Congress, consisting of all the most eminent physicists of all countries assembled in Paris, and of the jury of the Electrical Exhibition held there in 1881. He was also a member of the Consulting Council of the Electrical Exhibition held at the Crystal Palace, Sydenham, in 1882. He has held office in several societies. He acted for some time as honorary secretary of the Royal Astronomical Society, of which he was also president from 1864 to 1866. He was president of the Chemical Society from 1867 to 1869, and again in 1879-88, and was till his death one of its vice-presidents. He was for many years president of the London Institution, from which he retired and became secretary of the Royal Institution, in 1878, on the retirement of Mr. Spottiswoode, who was elected president of the Royal Society, but resigned the post in 1882. He was a corresponding member of the French Académie des Sciences, for the department of astronomy; also of the Imperial Academy of Sciences, St. Petersburg, the Philomathic Society of Paris, the Royal Society of Upsala, the Society of Agriculture and Commerce, Caen, the Society of Natural Science, Cherbourg, and the Berlin Chemical Society. Three foreign orders have been conferred upon him: Commander of the Legion of Honour, Commander of the Order of St. Maurice and St. Lazare, and Knight of the Order of the Rose, Brazil. Mr. de la Rue died, after a short illness, from pneumonia. The funeral was at Kensal Green on Tuesday last.

ROBERT STERLING NEWALL.

It is with extreme regret that we chronicle the death of Mr. Robert Sterling Newall, F.R.S., of Gateshead-on-Tyne, whose name is well known in connection with the invention and manufacture of wire rope, and the early history of telegraphy. Born in Dundee, in 1812, of an old and respectable Scotch family, he entered a mercantile office, and afterwards came to London, where his talents found more genial employment, under the late Mr. Robert M'Calmont, in connection with experiments on the rapid production of steam. In 1840 Mr. Newall took out a patent for making wire rope. It was this invention that made submarine telegraphy possible. He established works at Gateshead, and his firm manufactured and laid the Dover and Calais cable in 1850, the Holyhead and Howth and Port Patrick in 1852, and the Dover and Ostend, the Frith of Forth, and the Holland cables in 1853. In November, 1854, Mr. Newall suggested a cable from Varna to Balaclava to the Duke of Newcastle, then Minister for War. When this cable was completed, Mr. Newall received the thanks of the Duke of Newcastle. The Black Sea cable was laid by Mr. Newall in 1855, and the Red Sea cable in 1859. After laying the latter, Mr. Newall was wrecked in the "Alma," when his courage and coolness proved of the greatest help to the shipwrecked passengers. He devoted much of his time to scientific work, and had constructed a 25in. refracting telescope, which just before his death he offered as a gift to the University of Cambridge. To local matters Mr. Newall devoted much of his time. He was twice Mayor of Gateshead, and he was unanimously asked to be mayor again this year, when the British Association visit Newcastle.

THE

ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

ANXIOUS FOR DETAILS.

Through the courtesy of the editor of *Industries*, we were acquainted last week with the information he had received from Messrs. Ganz, of Buda-Pesth, relating to that firm having obtained a practical alternate-current motor. It seemed to us, however, that it was only right the initiative of our contemporary should be respected, and, so far as we know, credit must be given to *Industries* for being first to bring this matter before the English public. We hope shortly to be able to give further details of the motor, with drawings, but the vista opened out for immediate development of the electrical industry in regard to transmission of power, if this motor be as economical and successful as is claimed for it, is almost brilliant enough to take one's breath away. The one thing needful, might be the phrase used in connection with an economical alternate-current motor, and if this is really to be had there is no possible means of estimating the business to be transacted in electrical matters in the immediate future.

We write in this strain, although we know that the advocates of alternate currents have not thoroughly grasped the problems before them in dealing with vast networks of underground wires. The writer claims to have been the first to point out the necessity for taking into consideration what is now termed self and mutual induction, and also certain questions connected with alternate current distribution which are now becoming prominent. The rising class of electricians is inclined to despise some of the old-fashioned work of Willoughby Smith, F. C. Webb, and others, in face of the brilliant suggestions and hypotheses introduced by the younger men. Mr. Sprague must at times laugh to himself to find how far the views advocated by him nearly a quarter of a century ago are, under other auspices, becoming fashionable. Sermonising, however, is not now our object, nor is it the setting up of the ancient in face of the modern, but only to say, Don't despise the work of our elders, nor reckon it all rubbish. "There is nothing new under the sun" is an expression attributed to the wisest of the Eastern sages, but moderns take this as merely hyperbolic, and unhesitatingly affirm the doctrine of progress. Iron, coal, and water existed in the time of Solomon, but the combination resulting in the steam-engine did not. The action of magnets upon magnets, and wires conveying currents upon similar wires and upon magnets, has been descanted upon in textbooks for many years, but the various combinations to bring these actions into different practical uses are not even now all known, and probably never will be all known till human knowledge has reached the perfect state—a consummation, however much it may be desired, not yet within the bounds of our comprehension. In matters electrical, with so many in-

Digitized by Google

telligent minds directed upon the problems awaiting solution, any day may come

> "When the faithful pencil has designed
> Some bright idea of the master's mind,
> When a new world leaps out at his command,
> And ready Nature waits upon his hand."

Eleven years ago, Paul Jablochkoff, at the Paris Exhibition, paved the way for a new era—the electrical era. Three years later saw the Electrical Exhibition at Paris, and since then exhibitions have been held by the score, in all of which electrical apparatus took first place. It is to be hoped that Messrs. Ganz will see their way to exhibit this new motor at the Paris Exhibition to be opened on Sunday, May 5th. Be that as it may, the introduction of the motor, if it is all that is claimed for it, will stamp the year as fixing the time of a new departure. There have been rumours as to the success and the non-success of previous inventors in this direction—generally their non-success—but nothing very definite could be elicited as to the amount of failure or success. We have before said, and we maintain our contention, that unless an economical alternate-current motor is to hand, the multiplication of central alternate-current stations is a mistake. With such a motor many of our objections fall to the ground, for light must become, as it were, a bye product, and be produced in this way in a manner sufficiently cheap to defy competition from gas.

The figures and information given by our contemporary intimate that the motor requires one circuit only, that it is capable of starting under a load, and has as fairly high efficiency. The figures show a commercial efficiency of from 77 to 81 per cent. in trials which are stated to have been carried out under slightly adverse conditions. All electricians await fuller and complete information with great interest, and we sincerely trust their ardour may not be damped by subsequent figures, and that the machine is quite equal to what we are led to expect.

PROF. ELIHU THOMSON'S NEW METHOD OF REGULATING CURRENT OR POTENTIAL IN THE SECONDARIES OF TRANSFORMERS.

It is but a few years since the designing of electro-magnetic machinery, in the broad sense of the word, was more a matter of trial and error than of calculation; and although in the case of the dynamo good machines were developed from the process, it was not until the work of Hopkinson, Kapp, and others on the construction of these machines appeared that dynamo-building can be said to have been reduced to an accurate scientific basis.

The principal factor which characterises the new method of dynamo construction is the treatment of the magnetic circuit in the same manner as the electric, so that the "resistance" of the magnetic circuit has come to be quite as important a consideration as the electric.

Without entering further into the importance of taking this fact into account, we desire to draw attention to a beautiful application by Prof. Elihu Thomson of the theory of magnetic resistance to the regulation of alternating-current apparatus, so that either constant potential or constant current can be maintained in the secondaries of transformers, independent of the external resistance of the circuits. While primarily designed for the purpose of maintaining constant alternating currents such as would be required for arc lamps, the method is applicable to other purposes, as will be described later. The regulation is effected by the direct action of the lines of magnetic force themselves, in concentrating or focusing themselves across a narrow non-magnetic space, forming a partial break in what would otherwise be a perfectly closed magnetic circuit for the magnetism developed by the current of the coil in question.

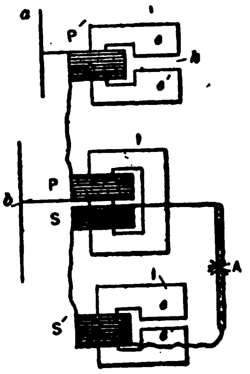

Fig. 1.

The method employed by Prof. Thomson will be best understood by referring to the diagram (Fig. 1). Here *a* and *b* are alternating current constant potential mains, the coil P being connected to them as a primary, S being the secondary, and both being wound on the same core. We will suppose that the number of turns in P or in any coil in circuit with it, as P′, is such that, having reference to the potential of *a b*, very little current will pass in P when the circuit of S is open. P′ is an additional coil wound on an iron core, I, in which core the alternating currents will obviously produce an alternating magnetism, and if the core of this coil were continued around so as to be endless, there would be a magnetic circuit entirely closed and a maximum of reactive effect in the coil P′ opposing the passage of current from *a* to *b*. Instead, however, of making the magnetic circuit completely closed, the core is provided with projections, *e e′*, which are brought rather closely together, with, however, a determinate air space between them, forming a partial break in the closure of the magnetic circuit for the magnetism developed by the current flowing from *a* to *b*. The space forms an air or magnetic resistance to the closure of the magnetic circuit for coils P′, and, as will be obvious, the more perfect the closure of the magnetic circuit at this variable point the greater will be the reaction upon the currents flowing from *a* to *b* through coils P′. During normal flow of currents from *a* to *b* there is a definite degree of closure of the magnetic circuit at *k*, dependent upon the width of the space and the number of magnetic lines of force which, with the given strength of magnetism in the core of P, may force themselves across the space. If there is any tendency to increase in the magnetism of the core of P′, the lines of force concentrate or mass themselves together in the space across *k* and become less diffused. By this means the degree of closure of the magnetic circuit of the core is increased and the reaction in coils P′ increased. This variation of partial magnetic closure or variation of magnetic resistance obviously takes place independently of the magnetic circuit formed by the core threading the coils S.

Leaving out of consideration the coil S′ in the circuit of S, the operation in regulating or adjusting the current in the circuit of secondary S is as follows: When there is a tendency to increase of current in the circuit of S, due to decrease of resistance, there is an attendant decrease in the counter E.M.F. of the primary coil P, as is well understood, and there would hence be a tendency to increase of flow in the coil P; but with an increase of flow in the coils of P there is also an increase in the coils of P′, and an increase in the number of lines of magnetism which pass over the magnetic resistance at *k* is produced. Inasmuch as the reaction of the coil P′ depends upon the

Digitized by Google

amount of magnetic disturbance set up in its core, or the number of lines passing from *e* to *e′*, it is obvious that the currents flowing from *a* to *b* will meet an increased self-inductive reaction, and the current on the secondary circuit S will be cut down.

As the rate of variation of closure at *k* may be varied by any desired means, and may, in fact, be determined by the width of the space *k*, it is obvious that the regulation or the adjustment of current in the circuit of S may be of any desired nature. The prime object is, however, to secure a practically constant current in the secondary circuit, and the width of the gap *k* is made such as to produce as near as may be that effect. The regulation of the current or potential in the secondary circuit might also be produced by variably closing a magnetic circuit developed by the secondary current and independently of the magnetic circuit of the primary current. Thus, as indicated at S′, the secondary current may pass through a coil which shall set up magnetic effects in a core having a partial magnetic closure of variable amount, as at *k*. In this case the same effect of a reduction in the current or potential of the secondary is produced by the variation in

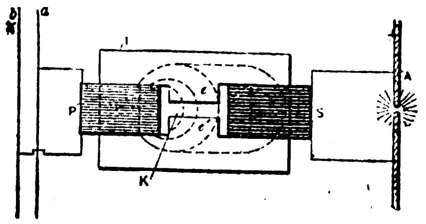

Fig. 2.

inductive reaction at the coil S′, secured by variably closing the magnetic circuit of the core of S′ at *k*. The effects produced by the variation of magnetic closure of the core excited by the secondary current might obviously be used alone or in conjunction with similar effects produced in the primary, as at P.

Instead of varying the magnetic closure of a core surrounded by a separate coil, as shown in Fig. 1, the magnetic circuit for the portions of core of the coils, P S, themselves may be variably closed, each portion of core having its magnetism closed without passing through the other portion, as shown in the coil (Figs. 2 and 3), which is the actual construction adopted. This is accomplished by means of

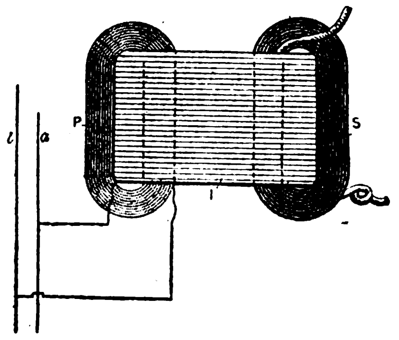

Fig. 3.

projections, *e e′*, extending from some part of the iron core or circuit which threads both the primary and secondary coils, the projections being separated from one another by a space K, forming a magnetic resistance similar to the space *k* of Fig. 1. By means of the variable magnetic resistance formed at K, the magnetism developed in the portion of core surrounded by the coil P is variably closed. In fact, the magnetism can work, as it were, through two magnetic circuits, one including the space or resistance K and the other including the portion of core passing through the coil S. The magnetic lines developed by the core or coil P, which pass through the air space at K and escape the coil S, produce wholly self-inductive effects, resulting in an opposition to the flow of the primary currents, while all the lines developed by the coil P which pass through the axis of the coil S result, as usual, in the production of secondary currents.

It will be readily seen that, as before described, any tendency to increase of the current flowing in coil P, resulting from a lowering of the resistance in the circuit of S, will be at once followed by the development of increased magnetisation of the proportion of core in coil P by the formation of increased magnetic lines across the air space, while at the same time the self-induction of the coil S itself will undergo an increase, owing to the fact that a path of variable closure for the magnetism in the core is likewise formed across the space K. In fact, the effect of a slight increase of current in the coil S would be to oppose the passage of the lines of force tending to pass through its coils from the coil P and cause them to be shunted across the space K. The result of all this is that the varying resistance in the circuit of the secondary, S, would receive a current which tends to be limited in strength and to be self-regulated through the provision of the variable magnetic resistance formed at the point K′ on partial closure of the magnetic circuit for the cores of the coils. As will be observed, the effects and principle of operation are much the same as before explained in connection with Fig. 1, excepting that the partially-closed path here permits the added effect due to the beating back of the inducing magnetism in S, and, in effect, results in a shunting from S of the magnetism developed by coil P.

In Fig. 2, A represents an arc lamp, fed with constant current from the secondary, P, although the primary coil, S, is subject to constant potentials. If the distance between

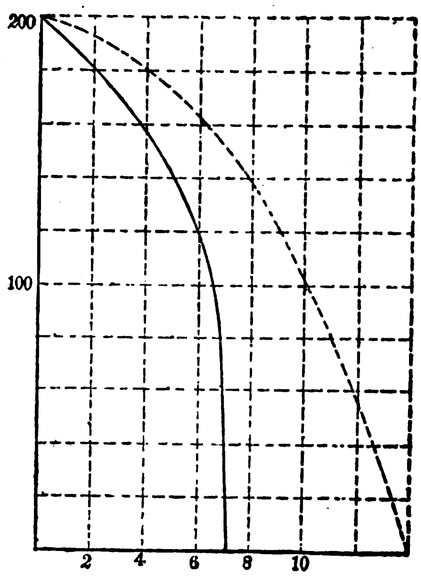

Fig. .

the projections, *e*, be properly determined, it will have the peculiar property of producing in the secondary coil, S, a droop or fall of E.M.F. when the resistance is cut out of the circuit, and this fall may be made nearly proportionate to the fall of the resistance, or diminishing resistance in the circuit, thus maintaining the current constant.

The partial closure of the magnetic circuit of the core, I, may be produced outside of both coils, P S, instead of between them. Other methods may also be employed, and a variety will readily suggest themselves.

The full line, Fig. 4, illustrates what may be called the "characteristic curve" of the secondary currents in such a coil as Fig. 2, the verticals or ordinates representing the E.M.F.'s evolved, and the horizontals or abscissas the current strengths corresponding thereto. At E.M.F.'s below 100, as shown, the curve is almost a vertical line, showing that a constant current is evolved at any resistance below that corresponding to a potential of 100. The dotted curve represents the case of drooping or falling potential with increase of current, such as is obtained with some special arrangements, such as that shown in Fig 1.

While, as stated above, the method is applicable primarily to the operation of arc lamps on constant potential alternating circuits, it has a variety of other uses. Thus, it may be employed to maintain constant current in a number of incandescent lamps placed in series, any one or all of which may be switched out of circuit without danger. Another application is the maintenance of a wire at uniform heat independent of the length in circuit. Still

Digitized by Google

another is the use of the method for maintaining a constant current in electric furnaces which, as is well known, are liable to sudden and great fluctuations in current, and thus are a constant menace to the dynamo feeding them. Other applications will readily suggest themselves, but enough have been mentioned to indicate the wide scope of Prof. Thomson's method of alternate current regulation.—*Electrical World.*

BERRY'S DOME ELECTRIC BELL.

The requirements of an electric bell are that it should be neat, simple, cheap, well made, and that it should ring with the minimum of battery power. Mr. F. H. Berry, of 18, Percival-street, Goswell-road, has brought out a self-contained dome electric bell, which has been designed to satisfy these requirements. The bell is shown in Fig. 1, mounted on a mahogany case, with silver-plated dome or bell. The working parts of the bell are hidden beneath the dome, and cannot be tampered with unless by unscrewing with a screwdriver.

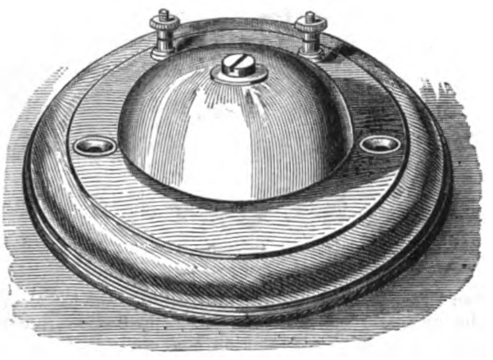

Fig. 1.

Fig. 2 shows the working parts of the bell, the dotted line showing the position of the dome. There is one magnet-coil only, but the power of both ends of the magnet are utilised by the provision of iron checks on the magnet, which attract the small armature or hammer placed alongside. This strikes the bell upon a knob or projection cast upon its inner surface. As there is only one bobbin, instead of two, this bell offers considerably less resistance

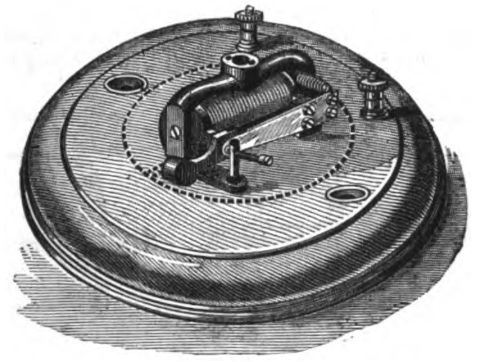

Fig. 2.

than the usual type, and works with less battery power. It rings very powerfully over 100 yards or so with a single Leclanche cell. The bell is very cheap, cheapness in this case being obtained, not by inferior materials and workmanship, but by the simplicity of construction, and considering the demand there exists for a really good and cheap electric bell, we should anticipate a very large sale for it.

Electrolysis by Alternating Currents.—The priority of observations on this subject is claimed by E. Drechsel in *Beiblätter* (1889, p. 13). He notes that the explosion of the gases is not caused by heating of the electrodes, as the same phenomenon occurs when the electrodes were of fusible metal, which afterwards show no trace of fusion.

UNDERGROUND CONDUITS AND ELECTRICAL CONDUCTORS.

BY JOHN B. VERITY (MEMBER).

(*Continued from page 320.*)

The Lake conduit shown in the illustration (Fig. 1) is made from the best stoneware clay, vitrified and well glazed. This conduit, said to be used with success by the United States Electric Lighting Company at Washington, is constructed with six compartments, each being 2½in. by 4½in. It is delivered in short lengths, and the joints are protected by stoneware covers set in cement.

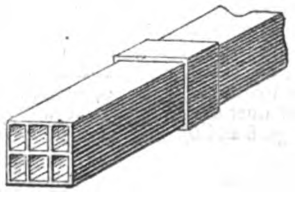

Fig. 1.

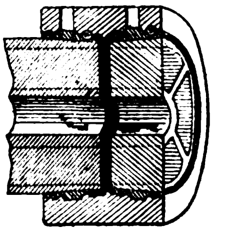

Fig. 3.

The Doulton conduit (Fig. 2) consists of a glazed earthenware pipe, in which the cables are laid, separated by toothed insulating partitions. A space at the bottom drains off the condensed moisture, which is got rid of by suitable traps. The joints are made like ordinary drainpipes.

A serious objection to such conduits seem to be the joints, which are made with cement. It is very difficult to break a cement joint without also breaking the pipe, and as it might be necessary at times to put in a new length, this could not well be done. Again, the rigidity of a cement joint is a disadvantage, as in laying earthenware pipes it becomes necessary at times to alter the alignment.

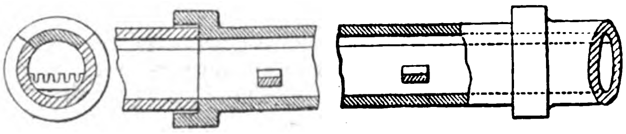

Fig. 2. The Doulton Conduit.

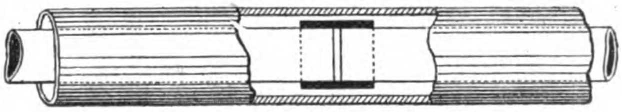
The Hurlbut conduit system (Fig. 3) was designed to overcome this difficulty by means of a flexible joint. The joint is shown in the diagram. C represents asbestos gaskets recessed into the coupling and resting against the pipe. B is a cavity formed between the asbestos gaskets, and is filled with a permanently plastic sealing material. A represents openings through which the sealing material is poured. It is claimed that such joints will always remain both flexible and hermetically sealed.



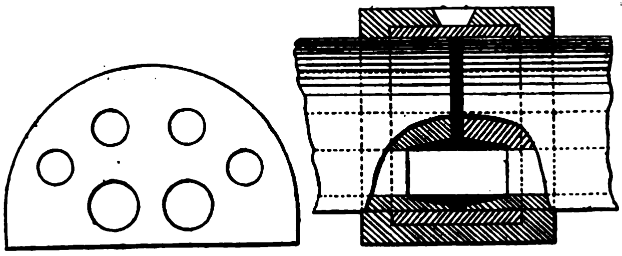


Fig. 4. Mr. B. Verity's Conduit.

Mr. J. B. Verity's conduit (Fig. 4) is a system of glazed stoneware clay conduit, with separate channel for each conductor; the joints are made as shown on diagram. The double cone-piece being inserted before the jointing material is run in, the special object of this conduit is to enable bare conductors to be used insulated only at the manholes or where they are likely to be handled. Experiments have proved this form to be capable of standing almost anything mechanically when laid on a fairly good bottom. Mr. Verity has also patented a system of glass tubes in iron pipes for the same purpose.

Pipes of glazed earthenware with several ducts form a good mechanical protection, being capable of resisting considerable crushing pressure, while the glazing both inside and outside provides also, under certain conditions, a first-class electrical protection. If it be desirable that the conduit should be formed of a non-conductor, then nothing could be better than such glazed earthenware, which also is of no great cost. The difficulty of maintaining good joints with earthenware pipes has been referred to some time ago in connection with conduits for telegraph purposes, several instances having been given by Mr. Preece and others of roots of trees, branches, and other vegetation having made their way through the joints.

Digitized by Google

Is this capable of being overcome by a flexible joint, which should at any rate, prevent joints giving through expansion and contraction?

The great disadvantage, however, to the use of earthenware pipes in many places in a city like London is the amount of space required for them; in fact, the difficulty of laying any conduit at all in some of our streets will be found simply enormous.

As a mechanical protection only, it is immaterial whether the conduit be a non-conductor or not. The simplest form of such a duct is, of course, an iron pipe, and the Western Union Telegraph Company, among others, have laid cast-iron pipes of 4in. and 5in. diameter, with manholes, at a distance of about 450ft. apart. In the majority of cases, however, the plan has been to lay a number of separate iron pipes in a concrete bed, by which arrangement the pipes can be crowded, or curved, or kept apart, as may best overcome any difficulties or obstacles met with underground. For instance, four pipes may be laid on the same level in two layers, or where only a narrow excavation can be made, the pipes can be curved round so that two pipes are abreast in four layers. In this way the trenching is often materially diminished. Screw-jointed, asphalted, wrought-iron pipes of two or three inches diameter, laid in hydraulic cement concrete, are said to present the greatest tightness of duct against gas and water, together with the greatest strength (Figs. 5 and 6).

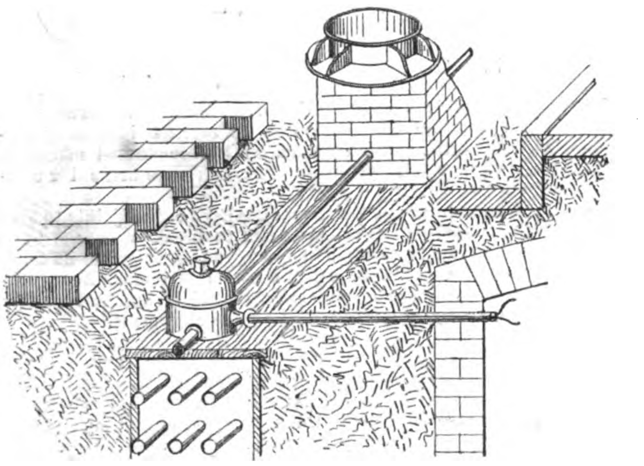

FIG. 5.

Cement lined sheet-iron pipes, however, possess some advantages, such, for instance, as smooth interiors, and the advantage of an iron enclosure, without the cable being brought into contact with it, and on the sheet-iron being eaten away, the cement still retains the pipe form. Zinc tubes again have been used, but are liable to be dented in, and asphalted concrete is often preferred to hydraulic cement concrete

Whatever system of pipes be used, it is important that they should have smooth interiors and close joints, and every conduit of whatever kind must be thoroughly well bedded, so as not to be liable to displacement from above.

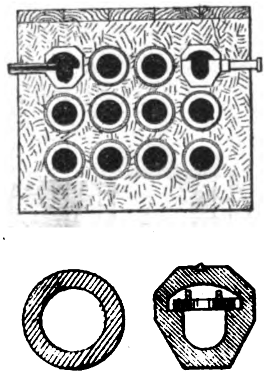

FIG. 6.

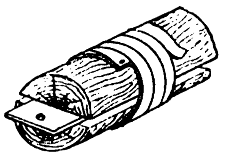

FIG. 7.

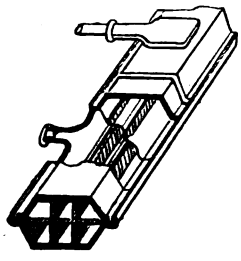

FIG. 8.

An ingenious conduit core (Fig. 7) has been devised by Mr. Chenoweth; a wooden cylindrical rod, 14 or 20ft. in length, is cut in two, forming two half-cylinders, and the space removed is occupied by an iron rod having a thickness equal to the portion sawed out. This forms the mandrill or core shown in the illustration; a ribbon of galvanised iron 1in. wide and a thickness of No. 27 gauge is wound spirally round this from end to end, securing the ends to the wood to prevent unwinding.

After painting the outside of the core with a mixture of clay, soapstone, and water, the core is placed in the ditch on crossed pieces of wood. If more than one duct is to be constructed, other cores are placed side by side, concrete is then well tamped round, bringing the top to an even level. The iron rod is then removed, as well as the two pieces of wood and the fastenings of the ribbon ends. When the cement hardens, the iron spiral can be drawn out at any manhole or unfinished portion of the work. It is claimed that the surface coating of clay and soapstone adheres to the interior of the duct and produces a smooth surface, while a monolithic structure is ensured water-tight by reason of its construction. I think this is another instance of American ingenuity.

The Johnstone iron conduit shown in the illustration (Fig. 8) is said to be very successful, and I saw portions of it as designed to be laid in New York City. It is made in sections about 6ft. long, and has six ducts; the three lower ones and the central duct on the top could be used for mains, and the two outer top ducts for house-to-house and street lighting. Where any house circuit is required the top half of a single section is taken and a new half-section with a hole in it, to which an elbow can be bolted, is fixed in its place.

A form of conduit made by Mr. W. E. Irish, of Cleveland (Fig. 9), is also worthy of notice. In the illustration the conduit consists of a tubular pipe cast in sections with flanges which are recessed on the inside to receive a rubber ring, forming a gasket between the two sections when bolted together. The conduit is provided with a longitudinal slot or opening along the top with inwardly-inclined sides, and flat surfaces on either side of the slot, to which the cover is secured by screws. To prevent the entrance of moisture through this slot, a strip of rubber or leather is first laid on the top of the flanges extended from one outer edge to the other. On this a solid wedge-shaped piece, which fits into the slot snugly, is placed, so that on the cover being screwed down the wedge, with the packing surrounding it, is forced into the slot, so as to seal it perfectly. It is claimed that there is great convenience in laying wires with this conduit, and that

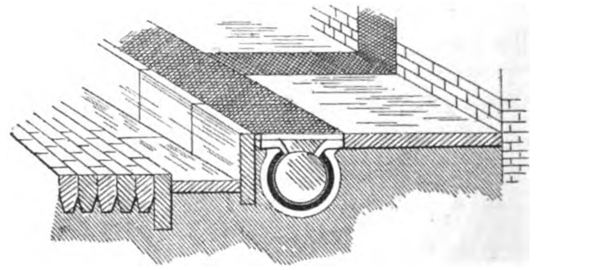

FIG. 9.

any wire can be tapped at any point by simply removing the cover and making the necessary connections. The illustration represents the conduit with a branch, also a junction-box, etc.

Fig. 10 represents Mr. J. E. H. Gordon's system as used by the Metropolitan Electric Supply Company. The cables are drawn into an iron pipe, and smaller iron pipes are led from the house junction-boxes to carry the wires for house lighting. Testing-boxes of a larger size, and built of brick, are provided at intervals.

It is generally admitted that an important point in underground work is good manholes. Mr. W. D. Sargent, in a paper read before the National Telephone Association, 1888, said that within reasonable limits it is almost impossible to get these manholes or working chambers too large, and that they have been compelled in many instances to rebuild and enlarge the manholes at first designed.

There is no doubt they must be of good size for convenience of drawing in and out, which is often a difficult matter, especially with lead-covered cables. In one instance, in Chicago, the manholes are built in octagon shape, in brick and cement, about 4ft. by 4ft., being made airtight with screw head and rubber gasket, and testing-boxes placed in them, so that troubles can be readily located, faulty wires drawn

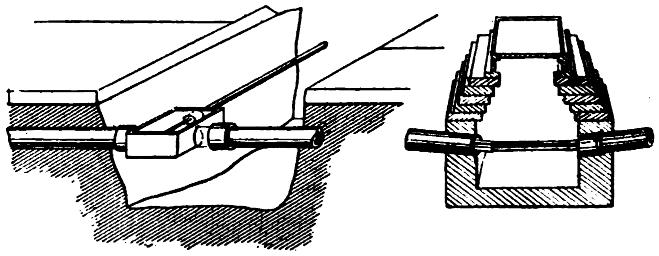

FIG. 10. Gordon's Conduit.

out, and good ones put in. In other cases the manholes vary from 3ft. 6in. to 5ft. deep, with iron kerbs and tops, and cement bottoms, and the covers made practically tight against water, many of the lids draining the water from the edge and collecting it in the centre, thus diminishing the liability to leakage at the gasket. With the Johnstone and the Irish conduits it is not necessary to provide for house connections, as the alteration can be made at any time afterwards when an application for light is received. But, as a rule, hand-distributing boxes made of cast iron, with screw head and rubber gasket, are fixed, one between every two houses, and after jointing the boxes are often filled with bituminous or insulating compound.

In the cement-lined pipe-conduit system one pipe is occasionally placed at the top for the house distribution, and connections made with the mains at the manholes. As to the frequency of these latter, much depends on the alignment of the conduit; at angles or changes of grade small manholes are necessary.

The combination kerb and gutter conduit (Fig. 11) shown in the illustration is worth notice. The kerb and gutter is made of fine concrete, one part of Portland cement, ten parts clean sharp sand, and

Digitized by Google

three parts of broken stone, and the exposed surfaces coated with a granilitic mixture $1\frac{1}{4}$in. thick such as is now used for some of our London pavements. A conduit for electrical conductors of any reasonable size can be formed as shown in the inner angle of the kerb with hand-holes from above closed with iron covers at intervals at intervals. The illustration is taken from the admirable report on underground wires by Major Raymond, the engineer commissioner for the district of Columbia, and which contains valuable information on many points.

It has been suggested some time ago that the kerbstones should be removed from busy thoroughfares and replaced with a hollow kerb edged with cast steel, and the suggestion may bear fruit in the future.

As I still have to deal with electrical conductors I cannot here refer to the general cost of laying conduits as at one time I proposed doing. The principal cost, however, of laying them is in making good, and this depends on the material of the road, the cheapest being macadam (varying from 5s. per square yard) whereas asphalte would be nearer 20s. per square yard.

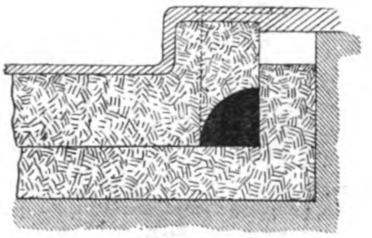

Fig. 11.

The difficulty of laying any form of conduit in some of our London streets must, as I have already said, be very great. The last comer will, of course, feel this the most; and although the Hydraulic Engineering Company may have recently had much trouble to find room for their pipes, the electric supply companies, again, will have an easier task than the Telephone Company, who are putting off the evil day.

As to what form of conduit is most suitable for London and our provincial cities there will be differences of opinion; but I trust the discussion following will narrow it down to a small issue, upon which such work can be undertaken with a tolerable surety of its lasting success.

There is really sufficient subject matter for a paper on conduits alone, and in taking up the question of underground conductors, I propose to chiefly restrict myself to a consideration of conductors for high-tension electric lighting circuits.

With regard, also, to underground conductors for low-tension work, I feel that the Edison system, as at present laid down, is thoroughly capable of filling all the requirements of house-to-house distribution. Many companies in the States and elsewhere are using it, and at the down-town station in New York it has been at work for the past six years successfully. In the recent discussion on Prof. Forbes' paper several points of interest concerning the Edison underground conductors were explained, which it would be unnecessary for me here to repeat. A full description of the latest developments of this system, with samples of the improved form of conductors, etc., are now on the ocean, and in the event of it being possible to provide another evening for a continued discussion of this paper, I shall be most happy to show and explain them.

Everyone must acknowledge the foresight shown in devising such a complete system of underground mains so long ago, and which, in spite of the all-round developments of electrical engineering, not only holds its own, but is still far ahead in completeness of any system for low-tension underground work. The Westinghouse Company have, I understand, acquired the rights for Great Britain, and presumably will use it in connection with large transformers for sub-centres. It may be also interesting to note that Messrs. Siemens have made concentric three-wire cables, which are being successfully used at Elberfeld, Geneva, and Mulhausen, and they state that the troubles from what would appear very complicated jointing have been satisfactorily overcome.

(To be continued).

BOARD OF TRADE ENQUIRY.

Wednesday, April 10.

Major Marindin, C.M.G., R.E., on behalf of the Board of Trade, resumed the enquiry at the Westminster Town Hall, for the purpose of hearing, on the part of a number of electric lighting corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

Sir Wm. Thomson wished to say, with reference to the answer he gave that one of the secondary supply wires ought to be connected in every case with the earth, that it was an opinion he arrived at after very careful consideration. Now that the pressure was proposed to be very much higher it would be dangerous to life, or, at all events, it would produce a very great shock if the metal-work of the lamps was at any such potential as 1,000 volts difference from the earth. There was no danger from fire. There would be an inconvenient shock if a person standing on a damp floor were touching a water-pipe or the lamp fittings. The larger the transformer, the larger the electrostatic capacity, and the greater would be the amount of the shock. His proposal was simply to connect one of the supply wires to the water-pipes; to let that be done through resistance of 10,000 or 5,000 ohms, and the result would be even in the case of a dead earth on the supply wire.

Mr. C. A. Cripps occupied a considerable part of the morning's proceedings by reading the draft agreement between the Metropolitan Electric Supply Company and the Strand District Board of Works, which had been drawn up by Mr. B. Maurice.

Mr. Moulton, Q.C., then opened his case for the Chelsea Electricity Supply Company, and in the course of his address said that it was the desire of all the representatives of the other companies who intended to give the continuous supply to do all that lay in their power to shorten the enquiry, and to assist the inspector by stating the points common to their various cases. That was to say, that in opening the case on behalf of the Chelsea Company he would as far as possible open the general case with regard to the direct supply system, especially with the use of storage batteries, simply so far as he was dealing with the scientific aspects of the question. He thought that their interests, so far as they came into conflict at all, came into conflict only on the question of area; but all the companies who proposed to use the direct supply had in common merits which were identical, and therefore, having stated the Chelsea Company's case, he would not have to repeat himself on behalf of the Electric Power Storage Company, and he would save the counsel who appeared for the Kensington and Knightsbridge Company and for the Westminster Company from the necessity of troubling the inspector with the same scientific details. He might also say that he appeared for the Telephone Company in order to put before him (the inspector) certain points that were now felt to be necessary to be mentioned, owing to the turn that some of the evidence had taken; but as he would have an opportunity of addressing him in opening the case before the enquiry was ended, he was not going in any way to deal with the evidence adduced on the part of the two companies whose cases had been already opened. The question of how far the evidence conflicted with the interests of his clients he would be able to show after all the evidence had been heard. The case of those for whom he was now speaking might be, he thought, fairly stated in this way. They were of opinion that the steps taken in 1883 and 1884, after very long and patient consideration of the subject, by the Board of Trade, were right substantially, and that there was no reason why they should be now departed from. He did not mean to say that knowledge and experience had not increased. He would be very sorry if that had been the case, but he thought that the bearing of electrical knowledge on the practical problem with which those electrical orders were intended to deal, had only justified and strengthened the grounds for the conclusions to which the Board of Trade then came. In 1882 the Electric Lighting Act was passed, in his opinion, under the influence of very strong feelings of what he might call a political kind. He did not mean to say that it was a party measure, but he did think that the Act was injured very seriously by the unmeaning importance which was given to certain political considerations as to the position of local authorities, and that it had one blot in it, which practically prevented electric lighting being carried out. He meant that the terms under which it could be done were given under pressure from the municipal authorities, and were such as could give no well-founded hope to undertakers of expecting a fair commercial return for their capital in the great majority of cases. That condition of things was altered by the Act of 1888. It was not one with which he could in all respects sympathise, but it did make some concessions to electric lighting companies in general, and admitted that the previous legislation was in error, owing to the unfavourable nature of the terms that it gave to electric lighting undertakings so far as the period of concession was concerned. That blunder, as admitted by the Legislature and corrected, did not affect in any way what the Board of Trade had to do in 1883. In that year the problem was this: Given a public need or a public desire for electric lighting, what was the fairest form of that special legislation which would limit and define the powers of the undertakers in each case? That was a problem which the legislation of 1882 had never attempted to deal with, and had most wisely left to the Board of Trade. The question of what the executive regulations should be was one with which the Legislature was thoroughly incompetent to deal with until the substantial problem had been worked out by such a body as the Board of Trade who had only the interest of the public at heart, and who, at the same time, could get the very best advice on the subject. What was the result during 1883, when there were many applications for provisional orders, a great number of which, he thought, but for that Act of 1882 would have been successfully carried out? Why, that the whole question on the receipt of those orders—or rather months before—had been most carefully thought out by members of the Board of Trade, and a model order drawn up, every line of which had been subjected to the closest examination and discussed, and the gentleman who had the shaping into legal form of that order was one for whose ability no one could help feeling the deepest respect. The case of the speaker's clients was that their provisional order was a right one, that it did even-handed justice between the local authorities and the companies; that it was not framed with anything like disregard to the claims of the local authority; and that the latter would do wisely to entrust to the company the lighting of their areas if they took upon them the responsibilities imposed upon them by that order. His company thought that as a company that went and asked for the powers of becoming undertakers for a district in London they ought to be willing to put themselves under such restrictions and responsibilities because under the period now allowed by the Legislature they would be able to do their duty with a fair and reasonable expectation of a proper commercial return. And he would say that where companies had at-

Digitized by Google

tempted seriously to vary that order the Board of Trade should, in the interests of all parties concerned, decline to accede to their proposals, and that, practically, the model order settled in 1883 should be the order for the area they sought powers over. The Chelsea Company, that he represented for the moment, was, he thought, the only one that was bold enough to obtain, and try to carry out, an order under the terms of the 1882 Act, but it had a clause in the model order which was a most reasonable addition—namely, that supposing any general Act was passed later making the terms as to length of concession more favourable to electric lighting undertakings, they should have the benefit of it. With that very proper addition it took the model order, so far as he knew, *in extenso*, without any change of a material character. In 1886 they obtained those powers, but till the Act of 1888 was passed they were unable to set to work, because they could not get their capital. As soon as that Act was passed the capital was obtained and work commenced. Dealing with the special case of the Chelsea Company, let him consider what was the idea of those provisional orders. The particular form of provisional order in respect to area was a matter of exceptional consideration, even compared with the other cases of those orders, and the notion at the time was that a company should not have an area given to it unless it was prepared, in return for the privilege of the concession, to lay out a certain amount of capital within that area in actual works; and the reason was this, that they were going there for powers for an almost unknown industry—he would not say unknown in the sense of its never having been tried, but house-to-house lighting was a novelty—they were applying for an area over which they would have power to break up the streets, and it was said that in return for the order the inhabitants of the area, as well as the general public, had a right to demand from them that there should be a *bona fide* attempt to carry out the work, and that a sum of money proportionate to the circumstances of the case should be actually expended in works in the area in order that that attempt might be a real and not a sham one, merely for the purpose of keeping the area in their hands until they disposed of it for their financial good. One of the most important things to be gained by that was an increase of experience to the public, and it was most necessary that powers granted over an area should not be held simply for the purpose of disposing of them unless there was real work done. He could not help thinking that those compulsory works were an essential feature of the model order. On the other hand, it would have been very hard on companies to say, "We will define what you must do and all you can do." It would have been very hard on companies to do the pioneer work of putting down their mains at whatever cost to themselves if their system was bad and if the circumstances were unsuitable, and then say, "If you do that successfully you shall do no more, and other people shall be in exactly the same position as you are in with respect to powers for that which is the natural extension of what you are doing." So that the principle applied was this: "You must do something; you must state in your order what you will be willing to do as a condition of your getting the order. When you have done that, you shall be allowed to go into further portions of the area as soon as any need arises." The consequence was that all areas were divided into two parts. There was a part in which they had to do the compulsory work, and another in which extensions might be made when the need arose. That was the scheme which they said ought still to be carried out, and he thought that substantially that was the scheme which all the people who were going for the direct supply were perfectly willing to accept. The question seemed to be one of statutory duties and regulations, and he thought that it would be substantially found that the contest lay between two classes—those who wanted to adhere strictly to the policy of the Board of Trade in 1883, and those who wanted to throw it over, and that the discussion was practically conterminous with the alternating and the direct systems. For a small area the direct supply was the cheapest, best, and most convenient. It was best to the consumer, it was most easily capable of being regulated, and was the one which was farthest from the risk of extinction. If they were to roam over a big area—if they wanted to hold London by occupying and lighting the best pieces, not over a small, but a large area, so that they could keep out competitors by taking up the cream of the work, and not being obliged to do more than that—then let them by all means use the transformer system. It had, no doubt, an enormous advantage in dealing with a straggling supply. Distance from the generating source, distance between the different distributing stations, was now a matter of comparatively little moment. That which it gave to the consumer was far less valuable, while the dangers which attended it were far greater. Its liability to immediate extinction was incurable, but the distance between the centres of generation or distribution was quite a trifling matter. Therefore, all that those who were supporting that system wanted was a huge area. Let the power once be given to occupy the cream of those places, whether Parliament gave them a monopoly or not was a matter of very little concern. If they could work the good bits on favourable terms, it would not be very easy to dispossess them of their strongholds by companies coming in on no more favourable terms. They could take the whole cream of London lighting and defy competition. That was an absolute abandonment of the policy of the 1883 order. His clients stood by that policy. What they wanted was that they should have a piece fairly to themselves, that they might work on the direct supply not very far from the generating stations, and they were willing to take the rough with the smooth—to bear the burden of lighting where it was profitable and less profitable, provided both cases were in the same area. If they were going to do that, and do it at a fair and reasonable price, it must be on those terms, that no competition be allowed where a company was doing its work well and complying with all the regulations of the Board of Trade. He thought he might say, without any hesitation, that in saying so he was only repeating the arguments which in 1883 the Board of Trade thought were conclusive in favour of districting as against competition. He would show how that body decided in favour of districting as against competition, and why his clients protested against the latter. Of all the industries that could be mentioned, he should think that there was none in which the gross of production was so intimately connected with the amplitude of demand. Electric lighting in small quantities was an exceedingly expensive luxury, but the larger the demand the smaller became the actual cost at which electricity could be produced. If they were to examine the balance-sheets of electric lighting undertakings it would be seen that the coal bill or the covering to the mains did not constitute anything like the major part of the cost of production—such as maintenance, supervision, and a variety of other things. But with regard to the use of their plant it was all important, if it was to be economical that the demand should be large in proportion to the plant so that it should be fully occupied, and all through the evidence that was given in 1882-3 it was shown that every electrical engineer who had any experience said that the condition of economical supply depended very largely upon the demand. Let them consider for a moment the position of the public in the matter; electricity, no doubt, had got a tremendous rival in gas, capable of supplying light without seriously crippling itself as regarded price. He felt that if electricity had to compete with gas on that score there was no doubt they had a very difficult struggle before them. He quite agreed that where there was only one company there was not that influence in lowering prices that they would have where there were two. But he contended that with even the moderate supervision of the Board of Trade, of the local authority, and the public, no electric company could make exorbitant profits. It would not dare to do it, because if it increased its price there would be a pressure of public opinion which would force the company to reduce it. There was no reason why an electric light company should not be willing to supply electricity cheaply, because by doing so it would immensely diminish the cost of production with the demand for it, and therefore it would have a strong stimulus on business grounds to lower the price. What they wanted was that kind of dealing which the Board of Trade thought fairest to everybody. They were prepared to take clauses which would compel them to do their work. They were prepared to have provisional competition, to take their order under a distinct understanding that if they did not do their duty others would be allowed to come in. They wanted that the Board of Trade should give to each company an area by itself of moderate size in which it could perform its duties at a reasonable price, and give a good service to the public, but let it do that unhampered. Let it have a fair field, and in a year or two, when things were no longer in project, but in actual working, it would be seen which system was the best. Whatever system was the best, all the others must adopt it if they were going to do their work thoroughly; otherwise competitors would come in. Let them not permit the electric lighting of London to be spoiled by immense concessions to companies which would be enabled to take all the good spots, and not to do it thoroughly, and which would commit them to a system which was by no means good to the consumer, because it would be granted upon terms which would render it almost impracticable for better systems to be introduced, except on ruinous terms of competition, rendered so by the unfair advantages asked for by those who sought to get enormous areas. On behalf of the direct supply, he put it before the inspector that it was of the very highest importance that orders should be granted to his clients and to those who, in fair-sized areas, were going to try that method of supply because it was unquestionably the best. That sounded a rather strong statement. Taking the evidence, it was admitted it was the best—that it alone was capable of being used with equal advantage for lighting, but with infinitely greater advantage for motive power, and he stood upon this that it was openly admitted by Lord Crawford and his other witnesses that they considered that motive power would be more important in the immediate future, and a greater demand for it than for lighting purposes. It was not only better but cheaper, and the only method by which they could avoid instantaneous extinction, and the only one in which there was anything to rely upon. No suggestion had been made as to any other method of obtaining that except the direct. The very properties that made it so much the best by virtue of there being storage in it were the very reasons for its being cheaper. People who had really experience in electric lighting would tell them that the curve of demand was an extraordinary one. The demand was exceedingly low until they came to a certain period of the day depending, of course, on the time of the year. When London was not befogged the curve ran up only to a certain height, but when it was befogged it went up in an extraordinary way, with the consequence that a great demand lasted for a time varying from 20 minutes to two hours. All those methods in which they made use of the electricity at the moment they made it were obliged to deal with the apex of that demand, and to be ready not only to perform that at the moment, but must have all their reserves at hand ready to compete with it. In fact, it was scarcely too much to say that with everyone of the systems put before the inspector up to that time, it would want the same plant for the maximum demand only for that comparatively short period of the day that it would want for the steady demand through the whole of the 24 hours. The moment they introduced storage batteries the whole of the demand need not be provided for in their generating plant. Whether they supplied from storage batteries or not, during the whole of those hours they could be using stores that had been piled up during the day; and if they combined the direct supply with storage they could have all their machines working, and all their batteries discharging during those hours, and, consequently, easily meeting every demand. With the direct supply they could feed into their mains at any point. In other words, they could connect their whole network together, and they might have any number of generating stations, or units in a station, and could utilise them for keeping up a uniform pressure at different points of the network of mains, thus securing the maximum advantage. If there was a break-

Digitized by Google

down anywhere, the whole of the rest of the generating plant would be *in situ* for the purpose of minimising the effect of that partial collapse of one feeder. In other words, they had *solidarité* throughout the whole system. Another advantage was that it was far the safest. He could not help thinking that the proposal of the London Electric Corporation not to keep their 10,000 volts current down at Deptford, but to send it round London within a half-inch main, was fraught with considerable unknown dangers. Now, his company stood in this position, that not even their enemies said that there was a lurking danger in their system. He agreed with Sir William Thomson that the difficulties in connection with any process were not insuperable, but in such cases the proportion of failures was proportionate to the difficulties. If he could show that their system was better, in that it gave a better supply, in that it was really cheaper, and in that it was safer, he thought he could put before the inspector grounds why he should, on behalf of the Board of Trade, assist his (Mr. Moulton's) clients in getting areas in which they could fairly under such circumstances, show how best they could do their duty to the public, and render the service they wished to do, and why the Board of Trade ought to use its influence with the Legislature in the way of supporting those claims.

Mr. R. E. Crompton was then called and examined by Mr. Moulton. He deposed that he had given great attention to designs for central stations. He had designed and carried out installations at Vienna and Le Mans, besides a central station at Kensington, all of which had worked satisfactorily. From his point of view the first thing that struck a designing engineer with regard to the direct supply with batteries was that it did not break down. It enabled the engines to be rapidly stopped, started, and exchanged during the time of heavy load without the public being aware that such changes were taking place. It was all very well to say that with the direct system without batteries similar things could be done. When the public got accustomed to a little flicker in the light that might be urged. But safety to the public he judged by results. The central station at Vienna supplied two of the largest theatres in the world, and he might say that the authorities there were now more anxious as to panics than they were in any part of the universe. The confidence that had been inspired in those authorities by the use of the electric light from the storage system had been such that all other means of lighting had been dispensed with. The nature of the demand in London varied, but he could describe it in residential London, which he took to be a very large part of the area. It was very little during the small hours of the night, and in winter from 8 o'clock a.m. to 3 o'clock in the afternoon. During the remainder of the time (that was from 3 o'clock in the afternoon to 7 o'clock) there was a rapid increase of load. If the load were represented by a diagram, it would mount so rapidly as to become like the slope of a very steep mountain. After 7 o'clock it suddenly descended to a point of about 60 per cent. maximum. There was a period between 8 and 10 o'clock, when there was a more level fall of the curve. Then it descended very speedily to 1 o'clock in the morning, after which there was a level line up to six in the morning, when the light began in winter. He found that there were about three hours of load at an average of 70 per cent. maximum, and 21 hours load of an average of only 4 per cent. maximum. That 4 per cent. would be distributed over something like six hours. That enabled them to make a large saving in generating plant. They tried to arrange that the engine and dynamos should run as near the full load as possible, in order to get the maximum of efficiency in units per pound of coal. The charge that went into the batteries was a low-tension one. The batteries were parallel with the dynamos. As to the cheapest mode of supplying house-to-house lighting in London, supposing it to be largely used, in his opinion, after careful calculation, there was no advantage in departing from the direct supply—he meant the ordinary well-known three-wire system designed by Dr. Hopkinson, and used in connection with storage. He had made every enquiry as to the transformer system, and he believed, as regarded the cheapness of supply, that there was no advantage in that system if they were lighting a close area. But his knowledge with regard to it was largely at second-hand. One condition, as he understood from Mr. Ferranti's evidence, was that by that system one had to keep an empty engine running to meet contingencies, which seemed to be extremely wasteful, especially when they were working at loads which formed a small percentage of their total. They would work most cheaply at their full load. Certain well-known makers of engines absolutely forbade running their engines lightly loaded. The most convenient unit area for supplying would be about half a square mile from each generating station, each of the latter supplying three to four distributing stations if they could be easily obtained. There was no great advantage in giving a large area unless the cost of the generating stations were very high. The cost of carrying a main sufficient for the distribution of about half a square mile for 2,000 yards, which would be the average distance from a wharf site, would be about £5,000, which would have to be added on to the capital charge.

SATURDAY, APRIL 13.

Mr. R. E. Crompton's examination, continued by Mr. Moulton. Witness said that, speaking as an electrician, he thought that the difficulties met with in practically carrying out underground mains for the distribution of electrical energy were increased in proportion to the E.M.F. employed in the mains, and that whereas in America extended practice had shown that those difficulties were not insurmountable, and dealt with satisfactorily every day so long as the pressure did not exceed 240 volts—the limit employed in the Edison three-wire system—yet the difficulties were so great that they had not been satisfactorily dealt with when the pressure arose to 1,000 volts, and of course the difficulty would be greater when 2,400 volts were used. The Edison system, as a rule, was worked with overhead mains. At Kensington he never cut off the electricity in order to make connections. The pressure was on constantly day and night. He believed that with high-tension mains it would be necessary to cut it off. He could not see how it was possible for men to work with a pressure of 1,000 volts. He had tried all the ways of running mains in pipes, and there were serious difficulties in the way proposed by Mr. Gordon of running several mains into one pipe. When it was necessary to withdraw a main from a pipe, it was necessary to withdraw them as a whole, as the Post Office did with telegraph wires.

Cross-examined by Mr. Pember, he said it would be an inconvenience to those who had the light taken off if it were necessary to take off the high pressure in order to make joints. He had not been in America, and was aware that there were 100 miles of mains there where arc lights were being worked with 2,000 volts, but was not aware that they worked satisfactorily. He admitted that they had been working for a short time. What he meant by saying that was that the cost of the up-keep was so great that they could not earn a dividend. It was a question of commercial, not of scientific, result. He had heard that Mr. Ferranti's system was at work in Nancy, where they were working at a pressure of 2,400 volts.

Mr. Pember: But surely that is an answer to your objection? What is your experience of working at that pressure?

Witness said that he had none.

Mr. Pember: While we are on the subject of the mains, let me ask this. You have spoken of the difficulty of making T joints on mains with the high pressure of 10,000 volts that we propose to employ. There won't be any joints at all on the main trunk lines.

Witness: Excuse me; I never imagined that.

Mr. Pember: That disappears?

Witness: Yes.

Mr. Pember: Then the only question is the making of T oints where the pressure is to be 2,400 volts?

Witness: That is so.

Mr. Pember: Are you not aware that we are working now with 2,000 volts?

Witness was not aware. With regard to the joints that would be on the mains they would be straight running joints, and the danger he suggested was that there would be a leakage at certain points, say, a mile from the works, and the result of the leakage would be that a "burn-out" would take place, resulting in the setting up of a short circuit between the works and the point of leakage, and that would result, of course, in enormously increasing the force of the current in amperes. It would be very difficult for him to say what the leakage would increase the current to, but it would be enormous for a short time. As a contractor he had had experience of both the alternating and transformer systems, and he believed he was in as fair a position to judge of their comparative merits as anybody else. He was most anxious to be fair to the alternating system, believing that it had its merits for scattered districts, for which he would unhesitatingly employ it; but for London he had always held the opinion that the concentrated nature of the lighting and the peculiar distribution of the area of lighting were such as to fit it particularly for the direct system employing storage. He had seen the transformer system at work at Salzburg, where there was a large station. It was rather longer than the Brighton station which they visited the preceding day. He said it was impossible for a lamp to burn 10 hours a day, and he might say that the question of the number of hours that lamps burned was the most important of all in the matter of electric lighting. He had calculated that his own lamps burned 1·1 hours a day. He believed that Mr. Ferranti's evidence on the point of the consumption of coal was based on the supposition that the lamps could burn 10 hours a day—which was an impossibility. The depreciation of the Chelsea cells would be 15 per cent. per annum, or somewhat less.

Cross-examined by Mr. C. A. Cripps, he said that the question of safety with regard to the Metropolitan system was in proportion to the pressure in volts. He had no experience of 1,000 volts, and he could not give an opinion as to whether that would be a safety light or not. His experience was that for 100,000 lights of 10 candles 19 tons of coal would be consumed. As to the cost of accumulators, he should say that if generating plant cost £200,000, the former would cost about £40,000 less. The cost of the distributing mains under his system would not be much more expensive than they would under the alternating. The maximum cost of his mains would be about £1,700 per mile. If the alternating current and transformer system were used instead of the accumulator system, they would have to add 50 per cent. extra on to their boiler and dynamo. He thought that as an engineer there ought to be no difficulty in allowing companies to compete.

Cross-examined by Mr. Shiress Will, he said he preferred the battery to the transformer system. He based his condemnation of the alternating system for London on the fact that, though it had been worked successfully with overhead wires in America, he was satisfied that the difficulties in placing the wires underground would be very great, and would greatly increase the expenses. He had satisfied himself that even in England, in cases where it had been worked with overhead wires, it had been a very costly system. He had only had second-hand experience of working on the alternating system. Of the battery one he had had personal experience. There were three ways in which electricity on the battery system could be supplied. First, a distribution of high-tension current to accumulators in each house; second, the distribution of high-tension currents to subsidiary stations, and then low-tension currents from those subsidiary stations; and third, to have accumulators at the generating stations, and from them distributing by low-tension. The difference in the size of wire to carry 1,000 and 2,000 volts pressure was very great. Theoretically, the wire would have to be 400 times larger in the case of the lower pressure, but it was not so in practice.

Cross-examined by Mr. Wallace, he said that the best area of supply would be half a square mile.

Cross-examined by Mr. Hewitt, he said that he thought it would be necessary to have a subway provided for the four companies in Kensington if there was to be competition, but he did not think it

Digitized by Google

would be practicable in High-street on account of the small space. He did not agree to the small area to be allotted to his company and the Chelsea Company.

Re-examined by Mr. Moulton, he said that the deterioration of concentric mains was due partly to electrolytic action. It would be costly to examine them for detecting a serious injury. Theoretically, fuses were as perfect a safeguard for electricity as a safety-valve in boilers. Theoretically, he believed that a boiler or steam-pipe should never burst with a safety-valve. The meters for the direct supply were perfectly reliable.

Mr. F. King (chief engineer to the Electric Power Storage Company) was next examined, and said that he had erected batteries and distributing apparatus at Chelsea from which they obtained a supply of 2,000 lamps of 10 c.p. The method adopted there was that the batteries were separated into two distinct halves. Each half was charged in series from the generating station. While the charge was proceeding to one-half, the other was supplying what lamps might be required, and the process was repeated until, when the two halves had been fully charged, they were both connected in parallel on to the supply mains to give the maximum output from the storage station. A battery could not be on the charging and discharging main at the same time. The tension in the discharging main was 100 volts. He commenced to work in the Chelsea district six weeks ago. They had one battery now supplying light, and another would be ready in a month. Their system was perfectly capable of performing the duties of the undertakers under the provisional order. He believed in what Mr. Crompton had said as to the superior character of the direct supply both for motors as well as for lights, because it was exceedingly steady. He did not believe that it was more costly than the transformer system. He believed, also, with Mr. Crompton, in working their plant with maximum efficiency at full load. Taking into consideration the economical circumstances of the use of plant, he believed that in the transformer and their system the comparative waste would be about equal.

Cross-examined by Mr. Graham, he said that his practical experience of the Electrical Power Storage system covered 2½ years. He had had no experience of it in lighting a large area. There was one generating station in the Chelsea district and three distributing stations immediately proposed. They proposed to send out in all their mains a tension varying from 1,500 to 2,000 volts. He did not anticipate any difficulty with insulation. The charging main would be about 1¼ miles. The discharge in amperes that they proposed to work at was 75 to 100. It might be taken that they would discharge at the former figure. The cells would be in groups of 50, giving out 75 amperes. The size of each cell would be 2½cwt., and the total weight of the cells would be 26 tons for 1,000 lamps of 10 c.p. The cost of each cell erected would be about £5. Of these they had 265, the price of which would be £1,325. He had no doubt about the accuracy of the statement. In Chelsea plant was being laid for 6,000 lamps, to be lighted from batteries alone. For extensions they contemplated using the engines and batteries together. Batteries could be maintained at a depreciation of 12½ per cent. The battery at Lloyd's Shipping House, in which the company had a maintenance contract, cost about 4½ per cent., and it had been running for three years. They had 224 cells there, giving about 500 lights. These lights ran about 1,000 hours per annum. He had advised the Chelsea Company that they could supply the maximum current for seven hours a day. The positive plates in the batteries would wear out in three years. He had never seen a genuinely worn-out negative one. He had seen negative plates seven years old.

In reply to Mr. Lyttleton, **Witness** added that he could not tell the cost of a generating station.

Cross-examined by Mr. Shiress Will, said he considered the battery system to be the best.

Re-examined by Mr. Moulton, he said that he had made a calculation, and he found that they could supply 100,000 lights or more at £2. 8s. per lamp running. The actual capacity of the Chelsea batteries would be 10 hours, and it would be economical to work with them for seven hours.

MONDAY, APRIL 15.

Mr. Shoolbred was first called, and cross-examined by Mr. Moulton. He said that he was now carrying out a central station for the Corporation of Bradford. The decision of the Corporation and himself was arrived at after careful examination of both systems. That which was chosen was the direct current low-pressure system. In his report he presented a comparative estimate of the cost of the direct and of the transformer system, and it was slightly in favour of the latter. He thought, speaking from memory, that there was a difference of £1,000. The one was £20,000, and the other £19,000, the latter being the cost of the transformer system. He considered, taking all circumstances into consideration, that the direct was the better system of the two for the town of Bradford for supplying not only light but power. The Corporation he had mentioned took the matter into consideration, and came to the same conclusion. At present the installation covered a very small part of the town, and was being laid down in conformity with that design for the rest. When they extended the installation it would add to the economy of the present arrangements to add storage batteries to the system, because they could thereby considerably relieve their generating plant.

Cross-examined by Mr. Pember, he said that he had been laying down electric light installations, some of them on a larger scale, for the last ten years. He had laid down some in London as well as in provincial towns. One that was quite as important as any that he had had in hand was that at the Forth Bridge works, which he considered of a more complicated character. Another was at Tate's sugar works at the East End of London. They began originally with a few arc lamps, but they had now 1,000 incandescent lamps. The installation was in one building, and not for the general supply of a large neighbourhood. He maintained, however, that the one at the Forth Bridge had a considerable analogy to a central station, supplying, as it did, a very large area under difficult circumstances, much more varying than would be the case in a central station. Its area was two sides of the Forth, a distance of 1½ miles long, and a quarter to half a mile wide at certain points. The number of lights now supplied there would be about 60 arc and close on 1,000 incandescent lamps. There were three stations—one on either bank of the river, and the other on an island in the middle of it. He had had no experience of the alternating system before he reported to the Bradford Corporation. Some of the members of the Corporation were good electricians, and could judge for themselves. They had visited the Kensington Court and Grosvenor Gallery installations, the merits of both of which were fully explained to them. It was very misleading to speak of an installation by the number of lights. They supplied current, not light: let customers do with it what they liked. The maximum supply for their machines was 1,800 amperes, and they had fixed on 115 volts as their pressure for supplying the town. At present they had three generating units. Each unit consisted of a boiler of 180 horse indicated, a steam engine 115, and a dynamo of 130 e.h.p.—450 h.p. indicated. Bradford was a manufacturing town, with a number of small industries requiring motive power to the extent of 10 to 20 h.p., and therefore the direct system was the best. He had much more confidence in direct than in alternating currents, and motive power ought to be taken into consideration as well as light. He had followed the matter very closely, and had not thought it his duty in any case to recommend alternating currents to his clients.

Cross-examined by Mr. Cripps, he said that there were no accumulators on the system, being merely a direct current low-pressure system.

Cross-examined by Mr. Shiress Will, he added that there were no distributing stations separated from the generating centre.

Mr. W. H. Knight, cross-examined by Mr. Moulton, said he had been an examiner in the Patent Office of the United States in class electricity, and was afterwards with the Brush and Thomson-Houston Company. He was now with the London Subway Company. He said that the points in which the transformer system was inferior were unreliability and the dangers of burning out the transformers, and its lack of economy when working on too small a load, not to mention its irregularity of light. The efficiency practically got was 50 per cent., and it could be worked up to 95 per cent. He thought the pressure quite safe at 1,000 volts. He thought that the Thomson-Houston Company had had a very severe lesson in connection with the alternating motor. He had followed almost every conceivable shape of the alternating motor, some of them being beautiful scientific devices, but they gave no satisfaction. After spending a year on the subject, the Thomson-Houston Company had given it up, and were now more directly engaged with direct current motors than anybody else. They were doing the largest electric lighting business in America as well as the largest motor business. They divided the alternating current business about equally with the Westinghouse Company.

Cross-examined by Mr. Pember, he said that he had had experience in America in regard to the loss of efficiency in the alternating system two years ago. He had heard that there were underground mains in connection with the Grosvenor Gallery working at a voltage of 2,400. With regard to underground mains, he did not say that the joints could not be made perfect.

Cross-examined by Mr. Cripps, he said there were no alternating generators in America over 100 h.p. The pressure in the alternating system there was 1,000 volts, which was thought safe enough. They were there, perhaps, more reckless in that respect than Englishmen. Under that voltage he had had a friend of his paralysed in Pittsburg by putting his hand on the terminals and the switchboard. The danger of burning out the transformers was due generally to leakage through defective insulation. He had had some experience of it.

Cross-examined by Mr. Shiress Will, he said he thought it was possible to work with a pressure of 2,000 volts from the generating machines to the transformers, provided they took proper means for insulation.

Mr. Will: As to the difficulty of working several dynamos at once on the same system with an alternating current, you say it has been done in America, but not kept on.

Witness: Yes; there is a slight difficulty. The dynamos get out of fuse, and while one lags behind it is worked as a motor with the other. They don't keep pace. The difficulty is not to be got over. It has been attempted to work them on the same shaft, and keep up by a mechanical device, but, of course, that makes one machine. Several machines coupled mechanically together are nothing more nor less than one large machine. He added that there were different methods of constructing transformers.

Mr. James Swinburne, examined by Mr. R. S. Wright, said that he was a member of several societies, and had been connected with gas works for some time. The cost eventually must come upon the consumers. The effect of "pirate" companies would be very disastrous because a company like the London or the Metropolitan would, by virtue of choosing all the most paying points in town, be able to undersell the Chelsea Company in Chelsea, and that would hold, even though it subjected itself to the compulsory clauses in Chelsea, because it would have such an advantage in other parts of London. Any deficiency by being under compulsion in Chelsea would be more than made up by lighting the rest of London, so that he thought the London and Metropolitan Companies would have a fair chance of beating the Chelsea Company out of Chelsea. He did not think that electricity was on the same footing as gas when the Gas Acts were passed, because electricity had now to compete with gas, which had its mains laid, and also with petroleum, the production of which had enormously increased recently, so that there was no question of a monopoly even if they gave one electric light company a whole district to itself. Then, again, the waste products of gas had become very valuable lately,

Digitized by Google

so that gas could be reduced in price very considerably if necessary. Therefore the competition of gas was sufficient so far as the interests of the public were concerned. With overhead wires, the alternating system for scattered towns with a transformer was a splendid way of lighting. It was much cheaper to use overhead wires if they could. In Boston electricity was cheaper than gas, the latter being 10s. per 1,000ft. The alternating system had the disadvantage that they had to depend on engines and boilers at the station instead of storage batteries at the sub-stations. He did not think storage was at all possible with the transformer system. The loss in transformers was very material when they were put in each house.

Cross-examined by Mr. Pember, he said he was very doubtful whether any electric light company cou'd compete with gas. Gas appealed to a very different public from the electric light, at present, at all events. The poor, who wanted warmth as well as light, would never think of taking the electric light. They would use, probably, petroleum, but the poor might want small electric motors.

Mr. T. O. Callender (manager of Callender's Bitumen Telegraph and Waterproof Company, at Erith), examined by Mr. Wright, said he had had great experience in making and laying underground mains. They had made cables for several hundred different installations. Both at home and abroad he had had experience in laying asphalte paving. In London, especially in the busy parts, there was considerable difficulty in laying anything, the space being already occupied by gas and water pipes, Post Office tubes, cellars, and coal places—all these things made it very difficult. They could not lay their mains close up to gas and water pipes, because the gas and water companies required a sufficient space to be left at the union with a pipe so that men could comfortably get their hands and arms down.

Mr. J. S. Raworth (superintendent engineer of the Anglo-American Brush Electric Light Company), examined by Mr. Wright, said he was also a member of the Committee of Engineers of the Chelsea Electricity Supply Company. They had to do with the alternating system in this respect that they had to manufacture an alternating-current apparatus on a fairly large scale. The Chelsea Company had erected a building at Draycott-place 127ft. by 41ft. 10in., with a basement for engineer and boiler purposes. The ultimate capacity of the station was 25,000 lamps. On Mr. Crompton's estimate it would be 52,000 lamps fixed, the relation between lamps fixed and those in use being two to one. He saw no reason to quarrel with Mr. Crompton's estimate.

Cross-examined by Mr. Pember, he said that the Brush Company were large shareholders in the Chelsea Company, and he believed that a part of his contract had been paid for in shares of that company.

Cross-examined by Mr. Lyttleton, he said that as regarded the Chelsea station the cost of the engines, dynamos, and boilers was £6,500.

Cross-examined by Mr. Shiress Will, he said that in the first instance they proposed to work entirely from the batteries—that was to say, in the early part of the day they charged up their batteries first one part and then the other part, and when the heavy part of the lighting came on at 3, 5, or 6 o'clock, according to the time of the year, they stopped the engines and put the two batteries in parallel and worked on to the lamps. The time during which the batteries gave out light did not exceed seven or eight hours. They would not put down the transformers until they had reached the full working capacity of their batteries—possibly in the course of two or three years. It was a continuous current transformer. They carried the direct current from the generating apparatus into a machine called a motor, and thence into a dynamo, which produced the low tension. The motor was connected to its centre of rotation, which generated currents at 100 volts. That entailed two losses—one in the motor and one in the dynamo, of from 20 to 25 per cent. It was a residential district they were dealing with. They did not propose to put down the transformers until the demand exceeded the supply of the batteries as originally designed.

Major-General Webber (managing director of the Chelsea Electricity Supp'y Corporation), examined by Mr. Wright, said he had had nine years' experience, having been divisional engineer for the Post Office for the East and South of England, including part of the metropolis, from 1870 to 1879. He had laid down a great many miles of electrical conductors in the telegraph service. He had also laid down several lines for the City of London and other places. His attention during that time had been chiefly called to the improvement of the system of distribution, subsequently to that period in connection with the distribution of electricity for electric lighting purposes. In 1883 he drew up a scheme for electric light distribution in the north-east of the parish of Chelsea. He also patented a system of laying copper conductors in iron cases. In 1884 he purchased the rights of the existing tenants at the central station in Draycott-place, and in the same year a syndicate was formed. In June, 1885, on his return from Egypt, statutory notices were issued for a provisional order, which was granted by the Board of Trade and confirmed by Parliament in September, 1885. The original area of supply was in the Hans Ward, and included 660 houses. The gross earning per lamp which he had studied in all parts of Europe varied enormously, but the average earnings of 27 lamps per house would be less than £27—between the two figures. He calculated that when they were supplying 10,000 lamps in use, running the maximum at the busiest hour, they ought fairly to earn a net profit of 10 to 12 per cent. free for dividend. The Chelsea capital was in no way "watered." There had been no promotion money—no preliminary expenses. They all agreed about the Act of 1882. An overhead line in London required very little capital—a few hundred pounds would do it. There were some wealthy houses in Chelsea, but a comparatively small number. He believed that the Grosvenor Gallery made an attempt to go overhead into Chelsea, and there was a petition got up in the parish against overhead wires signed by a large number of influential people. He highly approved of that petition.

PHYSICAL SOCIETY.—April 13.

Prof. Reinold, President, in the Chair.

Messrs. J. E. Dowson, W. M. Mordey, E. A. O'Keefe, C. Priest, A. Siemens, and W. B. Willans were elected members.

Mr. Shelford Bidwell, F.R.S., showed **"A Lecture Experiment illustrating the Effect of Heat on the Magnetic Susceptibility of Nickel,"** and **"An Experiment showing an Effect of Light on Magnetism."** In the first experiment a piece of nickel was attached to one side of a copper pendulum bob, which was held out of the vertical by bringing the nickel in contact with a fixed magnet. On placing a spirit-lamp flame below the nickel the bob was (after a short time) released, and oscillated until the nickel had cooled, when it was again attracted and the operation repeated itself. The second experiment had been recently shown before the Royal Society. One end of an iron bar which had been magnetised and then demagnetised was placed near a magnetometer needle. On directing a beam of light on the bar an immediate deflection of the needle resulted, and on cutting off the light the needle promptly returned to near its initial position. The direction of magnetisation induced by the light is the same as the previous magnetisation, and the bar seems to be in an unstable magnetic state. That the effect is due to light and not heat the author thinks is rendered probable by the suddenness of the action.

The **President** said he had tried the experiment himself, and failed to get any effect; but after seeing the arrangement of apparatus used, he believed his non-success due to the comparatively great distance between his bar and needle.

A **Member** asked if the results were different for different coloured rays, and **Prof. S. P. Thompson** enquired whether the magnitude of the effect varied with the intensity of illumination as in selenium, and also if any change was produced by altering the direction of vibration of the incident light?

Mr. G. M. Whipple wished to know whether any difference was produced by blackening the bars, and as bearing somewhat on the same subject mentioned an induction magnetometer in which an iron bar used was demagnetised by plunging in hot water. The results obtained were very irregular after the first magnetisation, and this may have been due to the instability shown to exist by Mr. Bidwell's experiment.

In reply, **Mr. Bidwell** said red light produces most effect, and blackening the bar makes the action much slower. As regards selenium, the character of the effect is similar, but he believed the causes to be different. Polarised light produces no change. In answer to Prof. Herschel, he said that any part of the bar is sensitive to light, and showed that illuminating both sides of the bar increased the effect.

Mr. G. M. Whipple read a **"Note on the Dark Flash seen in some Lightning Photographs."** After expressing his dissent from the explanations offered in the report of the Lightning Flash Committee of the Meteorological Society and Prof. Stokes respecting "ribbon lightning" and "dark flashes," the author described some experiments he had made on the subject. Ribbon lightning he conceived to be an effect produced by taking the photographs through windows, and to test this, lines on a blackboard were photographed; first direct, second through good plate glass placed obliquely, and third through window glass, the result being that double, triple, and ribbon flashes were closely imitated. As regards "dark flashes" the author believes the appearance due to the prints being taken in oblique light, and to be produced by successive reflection from the reduced silver, forming the dark line on the negative and the upper surface of the glass of the negative.

Prof. Perry suggested that this might be easily proved by examining a negative the prints from which show the dark flash.

Mr. Bailey pointed out that if the explanation given were correct, the dark line should be parallel to the bright one, and this he understood was not always the case.

Mr. Boys remarked that one dark flash exhibited minute wriggles not seen in the bright one, and **Mr. C. V. Burton** thought these might be due to irregularities in the upper surface of the negative.

Dr. Gladstone said he was not satisfied with Prof. Stokes's nitrous oxide explanation, but thought the phenomenon may be due to some kind of reversion. He also mentioned that a negative might probably be obtained from Mr. Shepherd, of Westbourne-grove.

As regards "multiple flashes," **Mr. Boys** said he had often seen seven or eight flashes traverse the same path in rapid succession.

On the motion of the President, the discussion was adjourned until next meeting, when Mr. Whipple hopes to exhibit the negative referred to, together with photographs of his experimental dark flashes.

"On Quartz as an Insulator," by **Mr. C. V. Boys, F.R.S.** In making quartz fibres the author observed that the ends of fibres broken during the shooting process coiled up into screws, and projected themselves against anything brought in their vicinity. After a short time they released themselves, and sprang back to their original position. This could be repeated indefinitely, and the only explanation he could think of was that the fibres were electrified. If so, then to exhibit such phenomena the insulating qualities of quartz must be very great, and experiments were shown to demonstrate this deduction. A small pair of charged gold leaves were suspended from a short quartz rod in a moistened atmosphere, and the deflection fell one quarter the original amount in about five hours. A clean glass rod under the same conditions would discharge the leaves in a few seconds. Dipping the quartz into water did not seem to diminish its insulating properties, and ordinary chemicals produce no permanent prejudicial effect. The author considers that quartz will be very useful in electrostatic apparatus, for the troublesome sulphuric acid may be dispensed with.

NEW COMPANIES REGISTERED.

British Tanning Company, Limited.—Registered by Sanderson, Holland, and Adkin, 46, Queen Victoria-street, E.C., with a capital of £70,000 in £1 shares. Object: to carry out an agreement, dated April 2, between E. Worms and J. Balé of the one part and H. Hodges, as trustee for the Company, of the other part, for the acquisition of certain letters patent for Great Britain and Ireland, granted to the said E. Worms and J. Balé for an invention for an improved process for tanning by the aid of electricity. The first subscribers are:

	Shares.
H. Hodges, 17 and 18, Basinghall-street, E.C.	1
A. Hodges, 23, St. Swithin's-lane	1
D. C. Lee, Thame, Oxon	1
H. Howse, 4, Comberton-road, Clapton	1
R. W. Rards, 46, Queen Victoria-street, E.C.	1
S. Pailthorpe, 1, Courthope-road, Hampstead	1
W. R. F. Livosey, 52, Queen Anne-street, W.	1

The number of Directors shall not be less than three, nor more than seven. The first to be appointed by the subscribers to the memorandum of association. Qualification, 250 shares. Remuneration, £800 per annum, and further 5 per cent. on the net profits after payment of 10 per cent. dividend.

Sante Fe Northern Railway Company, Limited.—Registered by Ashurst, Morris, Crisp, and Co., 6, Old Jewry, E.C., with a capital of £675,000, divided into 4,500 preference shares of £100, and 2,250 ordinary shares of £100 each. Object: to acquire, construct, complete and equip, maintain, prolong and work railways, and their appurtenances, tramways, lines of telegraph, telephones, or other means of communication, or appliances of a similar nature, in the Argentine Republic. The first subscribers are:

	Shares.
J. B. Went Henry, 16, Down-street, W.	1
C. W. Bloomfield, Acton	1
A. P. Baker, 135, Gladstone-road, Wimbledon	1
J. A. Holliday, Sudbury Villa, Asylum-road, Peckham	1
H. Hall, 89, Westmorland-place, City-road	1
J. B. Gelder, 115, Petherton-road, N.	1
E. F. Botwright, 23, Sutton-place, Hackney, E.	1

The number of Directors shall not be less than three nor more than seven. Qualification, £500 preferred shares. The first to be nominated by the majority of the subscribers to the memorandum of association. Remuneration, £2,250 per annum, payable quarterly, to be divided as the Board may determine.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended April 19 amounted to £2,179.

West India and Panama Telegraph Company.—The traffic receipts for the half-month ended April 15 show an increase of £720 as compared with the corresponding period.

Western and Brazilian Telegraph Company, Limited.—The receipts for the past week, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £1,057.

Great Northern Telegraph Company of Copenhagen.—This Company for the year 1888 state that the total receipts, including the balance brought forward, were £329,119, the expenses being £64,440. The Board propose the transfer for reserve and renewal fund of £55,555, and, after paying interim dividends amounting to £75,000, recommend a final dividend which will absorb £37,500, making a total of 7½ per cent.; the balance to be carried forward being £41,346. The investments during the past year on account of the reserve and renewal fund amounted to £37,218.

PROVISIONAL PATENTS, 1889.

APRIL 15.

6400. **The transmission of power from a motor engine to machinery or to another, or other, motor engines.** George Pinnington, 23, Chichester-street, Chester.

6410. **Improvements in galvanic cells for telephones.** Robert Acton Burnell, 101, Bishopsgate-street, London. (Theodor Wilms, Hamburg.)

6416. **An improvement in electrical contact makers or switches or connectors for the passage of a current of electricity.** Harry Scott Nowell, 47, Westcroft-square, Hammersmith.

6423. **Improvements in electrical motors and apparatus connected therewith, especially applicable to purposes of locomotion.** Alfred James Jarman, 4, Little Moorfields. (Complete specification.)

6429. **An improved electric apparatus.** Charles Wells, 22, Southampton-buildings, Chancery-lane, Middlesex.

6458. **Method of regulating the electric current produced by an electric machine driven by a motor having an irregular or variable speed.** Paul Hoho, 323, High Holborn, London.

APRIL 16.

6527. **Improvements relating to electro-motors.** Henry Harris Lake, 45, Southampton-buildings, London. (Nikola Tesla, United States.) (Complete specification.)

6544. **Improvements relating to electric incandescence lamps.** Albert Augustus Goldston, 4, South-street, Finsbury, London.

6547. **Automatic circuit-controllers for electric circuits.** Stanley Charles Cuthbert Currie, 24, Southampton-buildings, London. (Complete specification.)

APRIL 17.

6553. **An electric energy meter.** Sir William Thomson, 115, St. Vincent-street, Glasgow.

6557. **Improvements in cut-outs for electric circuits.** John Nealor Cooper, 5, Paignton-road, Stamford Hill, London.

6568. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Stafford.

6569. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Stafford.

6570. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Stafford.

6571. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Stafford.

6572. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Stafford.

6579. **A combined insulator and finial and lightning wire for telephone, telegraph, or other electric wires.** Hubert Feilden Jackson, Alfred Coleman, and Patrick Loftus, Prideaux Chambers, Change-alley, Sheffield. (Complete specification.)

6609. **Improved method and means of obtaining electricity.** William Boggett, 34, Southampton-buildings, London.

APRIL 18.

6622. **Improvements in electrical switches, fuses, cut-outs, ceiling-roses, lamp-holders, and the like.** Frank Geere Howard, Joseph Appleton, William Thomas Burbey, and Albert Edward Williamson, 91, Queen Victoria-street. (Complete specification.)

6628. **Improvements in laying and insulating mains for conveying electricity.** William Harding Scott and Laurence, Paris and Scott, Gothic Works, King-street, Norwich.

6654. **Method of employing magnetism in connection with locks for boxes, doors, and the like.** Iwan Bolaschoff, 41, Eastcheap.

6675. **Improvements in electrically-driven fans.** Henry Garwood Watel, 28, Southampton-buildings, London.

APRIL 20.

6713. **Improvements in electric lamp fittings.** Wilson Henry Sturge, 12, Cherry-street, Birmingham.

6728. **Improvements in the method of and means for the distribution of electrical energy by alternating currents.** Gisbert Kapp, 70, Market-street, Manchester.

6745. **Improvements in the method of and means for electrolysis of substances in a state of fusion.** Martin Kiliani, 46, Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

1888.

6382. **Electric automatic delivery box.** Miller. 8d.

6876. **Measuring electric currents.** Aron. 8d.

NOTES.

Continued.—The Gas Company of Malaga has now hauled down its colours and surrendered.

The Argentine Republic.—A 30,000-light Edison station is under way for Buenos Ayres.

Reading.—The gas was put out last week at Reading to see the effect of the electric light alone, and the members of the Corporation went round to inspect the lighting.

The Electric Light in Austria.—The municipal authorities of Bilin (Austria) have, we are informed, definitely decided to adopt a system of street lighting by electricity at a cost of about £2,400.

Electric Fire Alarms at Crewe.—The question of providing electric communication with the firemen has been brought forward at the Crewe Town Council, but the matter is adjourned for the present.

Conversazione.—We are informed that the President of the Institution of Electrical Engineers and Lady Thomson are about to issue invitations to the members for a *conversazione* on Friday, May 24th.

Personal.—Mr. Arthur W. Slater has withdrawn from partnership in the Galway Electric Company, and has transferred his interest therein to Mr. James Perry, who assumes all liability in connection therewith, and continues the business on his own account.

Telegraphs in Sweden.—The new tariff, equal to 7½d. per message, for local messages, which has been in force since the commencment of the year in Sweden, has largely increased the traffic. In many of the towns the increase amounts to more than 50 per cent.

Institution of Electrical Engineers.—The next meeting of the Institution will be held on Thursday, May 9, at 8 p.m., when Mr. Preece is expected to open the discussion on Dr. Oliver Lodge's paper on "Lightning, Lightning Conductors, and Lightning Protectors."

Underground Mains in Paris.—The work of laying the underground mains is going ahead on the boulevards, from the Porte Saint-Denis to the Grand Hotel. The mains are being laid in conduits 1·50m. high by 75cm. wide. They consist of bare cables run on porcelain insulators.

Dynamo Oil.—We have received a list price of specially prepared oils for engine cylinders and dynamos, from Messrs. W. H. Wilcox and Co., 36, Southwark-street. Messrs. Wilcox now issue a special dynamo oil, which is in large demand, for installations, and will send a small sample for trial to those wishing to test it.

Bordeaux.—The proposed installation for the Bordeaux Docks will shortly be carried into effect. It will consist of seven arc lamps (taking 30 amperes) upon the quays and six incandescents in the machine-room. The current will be furnished by two Gramme dynamos of 70 volts and 180 amperes, driven by a 30 h.p. steam engine.

The Telephone Amalgamation.—The *Financial News* understands that the telephone companies have found a way out of the difficulty in the way of their amalgamation created by the Postmaster-General, and that particulars of an amended scheme, to which his assent will not be necessary, will be placed before the shareholders immediately.

Enamel Insulation for Dynamos.—Mr. Benson Bidwell, writing to the *Electrical World*, points out that his patent No. 393,666, November 13, 1888, covers the entire principle of using vitreous material on thin metal sheets or cast metal drums for insulation of bare copper wire for dynamos, intimating that parties wishing to use it can do so on payment of a small royalty.

Lambeth.—The Vestry of Lambeth will consent to the application of the electric companies if they accept certain responsibilities with regard to compulsory lighting of the principal streets, such as Waterloo-bridge-road, Albert Embankment, Kennington-road, Wandsworth-road, Clapham-road, Dulwich-road, and other main roads in the district; otherwise they will oppose their consent to the orders.

Paris.—The new terminus hotel near the Saint Lazaire Station at Paris, appears to have been most comfortably installed. Amongst other things more or less luxurious, each room is provided with an Ader telephone, by means of which the traveller may transmit and make known his desires. The hotel will be lighted entirely by electricity, and we understand the installation will be carried out by the management.

Niagara.—The Buffalo papers, who know more about the behaviour of Niagara Falls than ourselves, suggest that, as the falls are generally frost-bound until far into May, any attempt to utilise the power at the Cave of the Winds, as proposed by Mr. Hamilton, could only result in the whole machinery being solidly embedded in ice, and carried away bodily at the thaw, and condemns any such suggestion as absolute foolishness.

A Gas Electric Meter.—Mr. Walter F. Smith, of Philadelphia, advocates an electric meter illustrated in the *Electrical World*, consisting of a combination of an electrolytic cell and a gasmeter. The gas generated in the cell is collected in a receiver, and is measured by a gasmeter and dials of much the usual kind. This arrangement, though ingenious and novel, would partake far too much, however, of the notorious bad character of gasmeters to be practically adopted.

Inner Temple.—Although the Inner Temple have summarily stopped the elaborate preparations which were being made for a central installation, they have in no way decided to discontinue the use of the electric light. On the contrary, we hear that they have instructed Messrs. Drake and Gorham, who were formerly connected with this work, to carry out the extensions to the existing installation, including the fixing of an 18 unit dynamo and some cells. These will be placed in the existing electric light shed.

Northampton.—An electric light company is in process of formation at Northampton, and we trust that this town, which had so early a try for priority of electric light in England, is now on the way of being really lighted up. Mr. J. W. March, of the Taunton Electric Light Company, who is staying in Northampton, has written to the local paper, pointing out the success of the Taunton installation, and advising those in authority to adopt the Thomson-Houston system, which has proved so satisfactory in that town.

Newington Vestry.—At the last meeting of this Vestry it was moved that no objection be offered to the draft provisional order lodged with the Board of Trade by the London Electric Supply Corporation, or any action

Digitized by Google

taken to watch the progress of the order through Parliament. It was generally felt that the Vestry need not move in the matter if the company were able to satisfy the Board of Trade that they were in a position to undertake to carry out the work. The motion was agreed to without discussion.

Barnsley.—At the meeting of the Barnsley Town Council last week, a question arose as to the better lighting of the town. A resolution, referring the matter to the committee, had been passed last October, and Mr. Tinker now expressed his desire to give notice of a motion in favour of the Council enquiring into the desirability of lighting the town by electricity. It was stated that the committee are preparing a report on the subject of lighting, and it was agreed to let the matter stand over until the next meeting.

The Telephone in Spain.—From recent statistics it is shown that 30 towns in Spain possess telephone systems, with a total of 4,585 subscribers, the tariffs ranging from 85 to 300 pesetas—say, £3 to £11—per year. Curiously enough, out of all these concessions 28 are held by private individuals, and only two by telephone companies. These are at Madrid, where the Sociedad General de Telefonos has 1,458 subscribers, and at Barcelona, where the Sociedad Española de Electricidad has 774. The remaining private enterprises range from 433 (at Bilbao) downwards. Madrid telephones have paid 10 per cent. for 1888.

Medical Electrolysis. — Dr. Dujardin - Beaumetz brought before the French Academy of Medicine on the 13th of March a patient cured of constriction of the œsophagus by electrolysis by Dr. Fort. The patient, who came from Nièvre, arrived in Paris on February 16. The œsophagus did not measure more than five millimetres in diameter, and only allowed with difficulty the passage of a few drops of soup. The patient now eats all kinds of food, he has gained 10lb. in weight, and the œsophagus now measures 14 centimetres in diameter. This is the first instance of the application of electrolysis to the cure of constriction of the œsophagus.

Old Students' Association.—A meeting of the City and Guilds Old Students' Association will be held at the Technical College, Finsbury, E.C., on Wednesday, May 8, at 7.45 p.m., when a paper will be read on "The Construction and Maintenance of Secondary Batteries," by J. Appleton, member. The following is an outline of the paper, which promises to be an interesting one: Theory of the secondary battery; brief history of its development; an ideal secondary battery; modern types of secondary batteries, their construction and maintenance; the direction in which improvements are wanted and are likely to be made; maintenance of secondary batteries.

A Smash at Berlin.—The following note on an accident to the Emperor's chandeliers appears in the *Pall Mall Gazette*: "The carrying out of the Imperial decree, 'Let there be electric light,' in the White Salon of the Palace at Berlin, has not been without its grave difficulties. In order to 'fix' the new arrangements, it was necessary to remove the crystal chandeliers to the factory of the electricians. But on its road thither an uncouth butcher's man drove his heavy cart against the waggon on which the chandeliers were being conveyed; there was a great crash, a sound as of a thousand crystal bells, and half of the chandeliers were broken into a thousand pieces."

The Telephone in Austria.—The authorities at Buda-Pesth having accepted the proposition made by the Austrian Minister of Commerce for the installation of direct telephonic communication between Vienna and Pesth, the works will be commenced as soon as the necessary preliminaries are arranged. The Chamber of Commerce of Pilsen has petitioned for a telephone service between its town and Vienna or, at least, Prague. The Chambers of Commerce of Trieste and Fiume have also asked for the establishment of communication by telephone between the two towns. Finally, the Government has authorised the construction of a line of silicium bronze between Trieste and Laibach.

An Inventor's Guide.—We have received a neat little book from Messrs. J. K. Fahie and Sons, of Dublin, members of the Institution of Electrical Engineers, entitled a "Handbook of Patent Law," new edition (London: Spon and Co., 6d.), which is not a mere dry digest of patent rules and charges, as is often the case with similar productions, but a readable little guide for inventors, containing a great deal of information of the kind required by would-be patentees, and some very useful "hints to inventors," or how they should go about patenting, and, what is more to the point, making money of it. We should advise such of our readers who are inventors and inexperienced in patenting to possess themselves of a copy.

Electricity in Cold Climates. — An incidental superiority of electricity in countries where intense cold often prevails is pointed out by Mr. J. Parke Channing, an inspector of mines in Michigan. Mr. Channing is of decided opinion that electricity seems to hold forth a promise to solve many problems in the way of transmission of power that have so far been impossible. He denounces steam underground as a nuisance, a danger, and wasteful, and states that compressed air, as has been demonstrated by careful tests at the Chapin Mine, has a low efficiency. He also specially points out that in a cold district like Lake Superior, where the freezing of steam and air pipes is a constant element of loss and delay, electric power has decided practical advantages on this score alone.

Electric Lighting in Brussels.—M. Somzée, who, it will be remembered, was chiefly remarkable in the past for having united in his own person the interests of both electric and gas lighting, and for whom the honour of being the inventor of the first successful incandescent lamp is yet claimed by a few enthusiastic admirers, has installed the electric light in his own house in the Rue du Palais. The current is supplied from a battery of 100 accumulators, charged by cable from the works of MM. Bouckhaert and Co. The first lighting up of M. Somzée's house took place on the occasion of a dinner at which General Boulanger was present.—The installation at the docks at Antwerp has been added to. It now consists of 48 Jablochkoff lamps (foyers), divided into 12 circuits, supplied by Gramme and Siemens dynamos.

The Electric Light at Brighton.—On Friday last Major Marindin concluded a Board of Trade enquiry with respect to the application of the Brighton Electric Lighting Company for a provisional order under the Electric Lighting Acts, 1882 and 1888, to enable them to extend their system. The Corporation opposed the granting of the order, because they thought that the company was financially insecure, because in detail its scheme was unworkable, and because the order gave the company the right to interfere with the roads for the purpose of carrying their

Digitized by Google

lines underground. The Hove Commissioners took a similar view, and their counsel contended that there was no general demand in Hove for electricity, and, if such were to be the case, the Hove Commissioners were thoroughly in a position to cope with the demand.

An Indian Agency.—Messrs. Volkart Bros., Bombay, have just established an Anglo-Indian engineering agency office, which, whilst forming part of the firm, is under the special management of trained engineers of technical education and of practical experience both in Europe and in India. The agency will have for its chief object the import of all and every description of plant and machinery, but will give special prominence to the introduction to India of plant for electric lighting, and for transmission of power by electricity. Branches are already established at Kurrachee, Tellicherry, Calicut, Cochin, Tuticorin, Madras, Delhi, Colombo, and at other agencies in the interior. The London office is at 31, Queen Victoria-street, E.C., and is under the superintendence of an engineer of over twelve years' practical experience in India. An agency of this kind should be highly beneficial in opening out the vast possibilities of electrical engineering in India.

Electrical Hoists for Mining Purposes.—In a report of the Californian Mining Bureau, it is stated that the first application of electricity to hoisting works for mining purposes in the West is at the Veteran Tunnel at Aspen, Colorado. The power is furnished by a Pelton wheel, with governor for regulating the flow of water. The wheel is situated 6,500ft. from where the power is applied, and drives a 500 volt Edison dynamo, which converts into electrical energy 92 per cent. of the power thus developed. The wheel is of 90 per cent. efficiency, and the energy available for work at the motor pulley is 74 per cent. of the water from the wheel. The motor operates a hoist over a shaft 200ft. deep, and also runs a train of nine waggons through a tunnel 1,000ft. in length. Formerly one man was required to each car, taking 20 minutes for the round trip. Now the entire train is run out and returned by one man in eight minutes.

The "Lahmeyer" Dynamo.—We have received from the Deutsche Elektricitäts-Werke (Garbe, Lahmeyer and Co.), Aachen, Aix-la-Chapelle, Germany, an interesting portfolio of illustrations and description of the "Lahmeyer" dynamo. This machine, which is very well known on the Continent and in America, has gained rapid ground for the excellence and simplicity of its construction, and the firm producing it have so many orders that they have been obliged to double their factory and plant. The "Lahmeyer" dynamo is one with double poles returning upon them selves on the outside in such a way as completely to encase the working parts in iron. The result is both great freedom from loss of magnetic lines of force affecting watches or ships' compasses, and also—a most important point in practice—complete protection from exterior damage from knocks or accidental falling of tools or other articles upon the coils. The firm have made arrangements to ship by Antwerp or Hamburg, and in certain situations the well-tested qualities of the "Lahmeyer" dynamo may secure them acceptance on the English market.

A New Open Circuit Battery.—An improvement in the porous cup of the Léclanche battery has been introduced, according to the *Electrical World*, by the National Galvanic Battery Company, of New York, with the object of increasing its life and efficiency. The new cup consists of a vitrified body, which is perforated, and all the cups are perforated alike, so as to obtain uniformity of action. Through the network thus formed the solution circulates freely, and current is available immediately upon the immersion of the cup in the liquid. In addition to the usual lead terminal head is a supplementary piece of platinum wire, which, being unoxidisable, allows the cell to work until the crushed carbon and oxide of manganese is thoroughly reduced. Tests of the battery, made by Mr. John A. Seely, electrician of the Metropolitan Telegraph and Telephone Company, show that after a short circuit of over five hours the current, which was originally one ampere, had still a strength of ·2 ampere. In another test the cell was placed in circuit with a resistance of 150 ohms for over 13 hours, after which it was at once connected with a vibrating bell, which it rang continuously for 137 hours.

Royal Meteorological Society.—At the meeting of this society, held on Wednesday, the 17th inst., at the Institution of Civil Engineers, Dr. W. Marcet, F.R.S., president, in the chair, a paper was read "On the Deaths caused by Lightning in England and Wales from 1852 to 1880, as recorded in the Returns of the Registrar-General," by Inspector-General R. Lawson, LL.D. The total number of deaths from lightning during the 29 years amounted to 546, of which 442 were of males, and 104 of females. In consequence of their greater exposure, the inhabitants of rural districts suffer more from lightning than those of towns. It appears, also, that vicinity to the west and south coasts reduces the chances of injury by lightning, and that distance from the coast and high land seems to increase them. In his paper "On the Rime-frost of January 6 and 7, 1889," by Mr. C. B. Plowright, F.L.S., the author gave an account of the very heavy rime-frost which occurred in the neighbourhood of King's Lynn on these days, when the fringe of ice-crystals upon twigs and branches of trees was about 2in. in length. The weight was so great that nearly all the telegraph wires were snapped and an immense number of branches of trees broken off.

A Large City Plant.—The city of St. Louis, U.S., is to have a very decent electric lighting plant, according to advice just to hand. The cost will be half a million dollars, and the concession has been awarded to the Indianapolis Jenney Company. The plant will be capable of maintaining 4,000 arc lights of 2,000-c.p. each, and 10,000 incandescent burners of the accumulator system. Of the 4,000 arc lights 2,226 will be used for lighting the streets, as stipulated in the contract, and 1,774 for private use in commercial buildings and elsewhere. Of the 10,000 incandescent lights more than 4,000 have already been disposed of. In the construction of the lines over 300 miles of wire will be used. Twenty miles will be placed in underground conduits, and the remainder strung overhead. The revenue from the contract with the city will be 166,439dols. a year, which, together with the receipts from private lighting, will bring about 300,000dols., from which the contractors expect to realise a handsome profit. The construction will give employment for eight months to 1,000 men in various capacities, and when the actual work of lighting begins 250 men will find steady work. The coal consumption will aggregate 100 tons per day.

New Issue of "Brush" Shares.—The Anglo-American Brush Corporation announce the further issue of £75,000 6 per cent. first mortgage debentures in bonds of £50, £100, and £500 each, upon the security of the

Digitized by Google

whole assets of the corporation. The debentures will be issued at par, and bear interest at 6 per cent., and will be redeemable at the rate of 105 per cent. on 1st June, 1903. The subscription list is to open to-day (Friday) and close the same day at 4 p.m. An interesting set of curves is sent with the prospectus, showing an advance in volume of business, from the amount in 1883 taken as 100, to 307·4 in 1888, or 356·9 including their continental business. The general charges remain practically the same, including the continental business for the whole period, showing a rise in gross profits to 342·9 English, or 498·8 with continental, as compared with 1883 taken as 100. We are glad to see this increased activity; greater business under these circumstances means greater profit, and greater business is constantly requiring fresh means of manufacture. We note that last year shows an increase of 70 per cent. in the gross profit, with only 7 per cent. increase in general charges, and the corporation have more orders now on hand than at any previous period.

Sulphate of Soda in Secondary Batteries.—The use of soda in secondary batteries, mentioned by Mr. Preece in his paper at the Society of Arts, is rapidly increasing in practice. The object of the addition is to prevent the accumulation of non-reducible sulphate of lead. We note that Mr. Preece has found the addition to work perfectly, and ascribes the invention to an accidental idea of Mr. Barber Starkey. It has, however, been advised on theoretical grounds by several chemists. It was suggested by Mr. Swinburne, at a meeting of the Telegraph-Engineers in 1886, and the theory was explained; we believe it has been used for some time back by Mr. Crompton in his batteries. The action depends on the slight solubility of lead sulphate in sulphate of soda. A little dissolves and is at once electrolysed, the lead being deposited. A little more sulphate is then dissolved, and so on. In cases of rapid charge a little caustic soda may be set free in the immediate neighbourhood of the plate, and dissolve the sulphate. There is obviously no advantage in beginning with the carbonate instead of the sulphate of soda, and the use of the carbonate has the disadvantage of causing a strong ebullition on being thrown in. Now that attention has been called again to the question, we may expect users of batteries to test the action in practice on their own cells.

A Wave Motor.—Water motors, to be worked not by the action of the tide or flow of water, but by the motion of the waves, have been proposed time and again, and specially recommended to the attention of electrical engineers—one in which air was to be compressed by the rise and fall of a heavy hollow buoy was practically tried on the coast line some time ago with fair success. A novel form of wave motor is proposed by Mr. John A. Rowe in the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders for March, 1889, which may be interesting to allude to. This was designed primarily for the important purpose of enabling a gun to be discharged at the moment of level keel; but the arrangement has developed into a new motor actuated by the rolling effect of the vessel—a force mentioned by the author for a 9,500 ton vessel rolling 30deg. as mounting to 3,000 h.p., though the proposal to recover this enormous power is not contemplated. He does, however, show that with a heavy balanced weight—fitted to a *fixed* piston, the cylinder moving with the ship—66 h.p., or even up to 264 h.p., might be obtained practically from such a ship, a force which might be applied to force water from the ship by pumps, and propel her as the "Waterwitch" is propelled; or air-pumps might be worked by this means for the furnaces or other purposes; and in anchored vessels near land or lighthouses, otherwise to utilise the rolling motion of waves.

City Guilds Institute.—The "Report to the Governors" of the City Guilds Institute of Technical Education, just issued, is exceedingly interesting, and the only regret is that the disappointment in the decision of the Drapers' Company to reduce their contribution to £2,000, being half only of the previous contribution, has resulted in the curtailment of the expenses of the institute in every department, and precludes any further development at present. The total of the students who have matriculated at the Central Institute is now 98 up to September, 1888. An interesting feature of the report is a table in detail giving particulars of the subsequent career of some of the most promising students. The same is done with day students at Finsbury, containing many well-known names in electrical engineering, ranging from assistants at works to full-blown professors. The total of students who received instruction at the Central Institution during the year is 431, including attendance at summer classes. At Finsbury there were 169 day students, and in the evening classes 1,012 tickets were taken by 914 students, 221 of whom entered as apprentices at half fees. The total donations to the institution show a falling off from £27,502 in 1887 to £24,195 in 1888; and this, in view of the spreading sense of the immense utility to England's commercial progress of these institutions, should lead those who have the means to give all help possible to these most advantageous organisations for adding increased productive power to the youth of the present generation.

Electric Power at Work.—It is interesting, says the *Western Electrician*, to visit a factory in which steam is utilised, and to watch the numerous machines in motion, tracing the power to its source from top floor to the engine-room; but it is far more wonderful to enter a factory in which the machines are operated by electrical energy. Here the machines revolve and do their work the same as in the other building, but the visitor is unable to see whence they get the power. In a great many instances the motor is cheaper, and it is always cleaner, and there is a saving in the wear and tear of machinery belting. It is only within the last year, however, that the manufacturers of Chicago have learnt the benefits to be derived from the use of the electric motor for driving heavy machinery. The city authorities did not wish to permit the motor to be run in connection with arc circuits, but numerous successful examples overcame their objections. The Baxter Motor Company undertook to introduce their machines, and numerous users in 18 different classes of establishments are now at work. The Sprague motor is also at work, and is greatly in demand for printers, those now in use ranging from 2 to 25 h.p. One large printing establishment in Chicago recently introduced a 10 h.p. motor, and was so well satisfied that it has been decided to run all the machinery in the establishment by electricity, and new motors will be introduced. The Chicago *Daily Herald* and *Tribune* are printed by electric motors. The C & C motors are also greatly used, principally for driving sewing machines, ventilating fans, and other light machinery.

Faure v. Julien.—The case between the holders of these patents has caused considerable interest in the States. The final result is an interdict from the Court to the Julien

Digitized by Google

Electric Company, because they are held to have infringed Faure's patent. The wording of these legal documents is amusing to minds trained in a wider sphere. Fancy the Julien Company—the naughty boy—corrected in the following language, which, however, is effective, if not idiomatic: "Now, therefore, we strictly command and enjoin you, the said the Julien Electric Company, and your officers, associates, and your clerks, agents, servants, and workmen, and each of you, under the penalties that may fall on you and each of you in case of disobedience, that you and each of you forthwith and for ever desist from directly or indirectly making or causing to be made, using or causing to be used, or vending to others to be used in any manner, any polarisation or secondary batteries containing or embodying the invention described and claimed in said first claim of said letters patent, as so limited by said disclaimer, to wit: Any polarisation or secondary batteries containing or embodying an electrode consisting of a support coated on one or more faces, with an active layer of absorptive substance such as metal or metallic compound, applied thereto in the form of a paint, paste, or cement, and practically insoluble in the electrolytic liquid so as to be or instantly become spongy, and thus capable of receiving or discharging electricity, as stated in said letters patent, and from vending to others to be used, or using or causing to be used in any manner, any secondary or polarisation batteries, thus heretofore constructed by you or any of you, and from infringing the first claim of said letters patent, as limited by said disclaimer, in any way whatsoever. Witness, the Hon. Melville W. Fuller, Chief Justice of the Supreme Court of the United States, at the City of New York, on the twelfth day of April, eighteen hundred and eighty-nine."

The Lighting of Chelmsford.—Although the exact details of the public lighting of Chelmsford have not yet been finally settled, Messrs. Crompton and Co. have the machinery well in hand and much of it is now ready. The town is to be lighted, as at present arranged, with 20 arc lamps and 110 incandescents of 32 c.p., and the town councillors of Chelmsford visited Messrs. Crompton's works last week to witness the trial of two of the incandescent lamps. The lamps were Edison-Swan lamps, 32 c.p., and were fixed to the wall of the works by iron brackets at a distance of 45 yards, each mounted in lanterns of different shapes. At 9 o'clock the light was turned on and proved most satisfactory. The lamps were moved to a distance of 70 yards apart, the average distance apart in the town, and again the lighting between the lamps was most satisfactory, being very much better than the adjacent gas lamps,; some of the councillors even suggesting the exclusive employment of these lamps as cheaper than arc lamps. The members of the Council then went through the town to settle upon the position of the lamps in the streets. At the Town Council next day the Lighting Committee presented a report as a result of their labours. After recalling the fact that Messrs. Crompton and Co. had undertaken to light the town by means of 20 arc lamps and 110 incandescent lamps for the annual sum of £700, the report stated that Messrs. Crompton had informed the committee that they should not require the use of the present gas lamps and standards, as they intended to provide their own lamp-posts. This, continued the report, put an entirely new complexion upon the question, and the committee felt at once that they were in a position to remodel the lighting of the whole district. It would be in the recollection of the Council that the total number of gas lamps was 188. Deducting 110 to be replaced by the incandescent lamps, it left 78 as the number superseded by the 20 arc lamps. But the Council a short time back resolved to add 14 gas lamps in different places, this making 124 lamps to be dealt with. The committee arrived at the conclusion that the arc lamps should be confined to the main road through the town. This absorbed 18 arc lamps, leaving a further margin of 18 incandescent lamps to be dealt with, or a total of 142. It was found that the distribution of lamps was very unequal in different parts of the town, being sometimes 50 to 60 yards apart, while in other places they were 110 yards apart. The committee, after seeing the experiments at the Arc Works, had come to the conclusion that if the incandescent lamps were placed about 70 yards apart the roads would be well lighted, while in roads where the traffic was not so great the distance might be increased to 100 yards. The committee determined to adopt this as a sort of standard, and, starting on this basis, it became manifest that a much larger number of lamps than were at the disposal of the committee would be required in order, as far as possible, to equalise the lighting of the whole district. They accordingly determined to lay before the Council a scheme which, although entailing some additional expense, would nevertheless recommend itself to the Council as dealing with the whole question in an equal and fair manner. The report stated that the result of the whole scheme was that the committee recommended the adoption of 18 arc lamps and 200 incandescent lamps. It had been arranged that the price of the arc lamps should be fixed at £22. 10s. each per annum, and the incandescent lamps £2. 6s. 10d. each per annum. The result would be: 18 arc lamps at £22. 10s. each, £405; 200 incandescent lamps at £2. 6s. 10d. each, £468. 6s. 8d.; total, £873. 6s. 8d. Under the old contract, the Council were paying £768 for gas lighting, and the 14 additional lamps would have added £56, so that the total cost would have been £824, and even at the reduced offer of the gas company, £3. 4s. per lamp, the cost of the scheme with gas would be £832 for lamps consuming 4½ cubic feet per hour, as against an equal number of incandescent lamps. If the Council determined to adopt their recommendation, the Lighting Committee were very strongly of opinion that the whole town would be lighted in a very superior manner to any provincial town of equal size, and, as it could not be questioned that the efficient lighting of a town not only conduced to the comfort of the inhabitants, but to the protection of property, the committee very urgently recommended the adoption of this scheme. The draft contract, which had been drawn out, was also read. The lighting is to be entered upon on the 9th of September next, and at any time during the five years over which the contract extends the Council will have power to terminate the contract if they consider the lighting is inefficient. There will be a fine of fourpence an hour for every arc lamp which goe out, and one halfpenny an hour for every incandescent lamp. A breakdown in the lighting will be provide against by reserve machinery. After some discussion as to the fines, the proposal was adopted *nem. con.*, and Chelmsford will now have the distinction of being the first English town to be thoroughly and carefully lighted by a well considered system of combined arc and incandescent lamps in a manner electrical engineers can approve.

TELEPHONE CONDUCTORS.

BY R. W. JAGGARD.

It is of great importance that the proper size of telephone wires should be ascertained, both from the commercial and from the scientific point of view. The two things to be considered are initial cost, and freedom from induction.

An experimental cable, laid on the Pennsylvania Railroad between the Broad-street and Thirty-second-street stations, in the spring of 1887, contains 53 conductors, 52 of them are number 16, and one is number 18, American gauge. The greater number of the conductors are used for telegraph purposes, and a part of the remainder for telephones.

About a year ago a phonoplex circuit, working between Philadelphia and Harrisburg, was introduced into the cable. The heavy inductive impulses used to operate this circuit caused considerable disturbance on the telephones. An attempt was made to ascertain which of the conductors was least disturbed by those inductive impulses, and it was found to be the 18-gauge conductor, the electrostatic capacity of which was about 0·11 microfarads per mile, while the 16-gauge conductors averaged about 0·14 microfarads measured on a cold night at a temperature of 12deg. Fahrenheit.

Substituting the 18-gauge conductor for one of the 16, we increase the resistance of the circuit, including the telephones, not quite 2 per cent.; but the electrostatic capacity is reduced over 20 per cent.

Two per cent. increase in the resistance of the circuit could not be felt in operating the telephones, but a decrease of 20 per cent. electrostatic capacity was clearly discernible in greatly lessening the inductive disturbances; and, on that account, the 18 gauge was selected for the most particular telephone circuit.

As a majority of telephone circuits diverging from the exchanges are less than a mile in length, it is evident that smaller-sized conductors with greater insulation should be used. Not that high insulation is desirable, but that the thicker the covering and the smaller surface of conductors is a principle that would be well to follow. This principle was proved conversely by using two 16-gauge conductors in place of a single conductor, which doubled the inductive disturbances, in the same proportion to the increase in electrostatic capacity; at the same time the resistance of the conductor was halved.

Carrying out the above principle, it is evident that small conductors are advantageous as long as the conductors are confined to cables within the area of cities; but when extending beyond city limits, they should be connected with wires of larger dimensions, especially so when metallic circuits are used, as in long-distance working. In cases of this kind conductors can be transposed and crossed on the poles to neutralise, or nearly so, all inductive disturbances.

There is another feature worthy of notice in laying up the conductors of a cable in order to reduce the electrostatic capacity. Cotton has exceedingly low electrostatic capacity, and, as in the case of the cable above mentioned, the conductors are all twisted tightly in the same direction like the strands of a rope, allowing the cable to absorb a minimum amount of the resin mixture, which has a much greater electrostatic capacity than cotton. By this means the electrostatic capacity of the conductors is very low.

It is very plain, therefore, that even for metallic circuit purposes there are no advantages to be gained by having the conductors twisted in pairs, as the cable then becomes more bulky, and fewer wires can be put in the same diameter of pipe. There is also a greater space within the cable itself to be filled up by the resin mixture, thereby increasing the electrostatic capacity.

In Brooklyn a No. 19 American gauge-conductor, having three windings, laid up in pairs, is reported as having a capacity of about 0·19 microfarads per mile, while this cable with a No. 16 conductor and two windings shows but 0·14 microfarads at the temperature mentioned.

The New York and New Jersey Telephone Company sent an electrician to Brooklyn to measure the electrostatic capacity of these conductors. That company is able to furnish comparative results.

Vice-President Thomson, of the Pennsylvania Railroad, uses two of these conductors in connection with the long-distance telephone lines to New York, and the service is said to be quite satisfactory.

It should be borne in mind that the electrostatic capacity of the metallic circuit is but one-fourth of the sum of the two sides when the capacity is taken as two separate conductors. Using the second wire in place of the ground for the other pole of the battery, with both conductors open at the distant end.

Similarly, the insulation resistance is double that of the sum of the resistance taken in the usual manner. For example: if one conductor should measure ten and the other five megohms per mile, when insulation is taken in the usual manner with one pole of the battery to earth. If the other pole of the battery is then connected to the second conductor, the lines of insulation resistance on one side, 10 megohms to earth and out of earth to the other conductor, five megohms, which makes the insulation of the metallic circuit 15 megohms per mile.

The foregoing hints are more especially intended for those who are about to open new telephone exchanges with underground or cable conductors in any form, and should receive the careful consideration of telephone managers, who, as a rule, are more commonly selected for business qualifications than electrical knowledge.

Electricians, as a general rule, are not good business men, and managers generally copy after some other managers, but "if the blind lead the blind they both fall into the ditch," which is the scriptural name for conduit.

The use of large size conductors in short-distance telephone working reminds me of the lack of scientific knowledge when the first Morse telegraph was put into operation. They had an idea that the same size conductor should be used in making the relay that was used for building a line, and thereby employed a No. 14 copper wire to wind upon the iron core. Sixty cells of Grove's battery were required to operate a line 40 miles long, and the magnetic effect was so weak that it required the most delicate adjustment to enable the armature to be moved. With that sized wire but few convolutions were brought into proximity to the iron core. This difficulty was overcome by using a wire of smaller dimensions.

It can be readily seen, therefore, that large-sized conductors are not always advantageous.

WHY SOME INVENTIONS DO NOT PAY.

BY S. F. WALKER.

One reason is that some inventors never complete their work. And there are two offenders of this kind. One set of men, as your correspondent, Mr. Bernhard Dukes, very properly pointed out, persist in inventing things they know nothing whatever about, and are therefore constantly posed by some trifling difficulty that anyone who understands the subject could have helped them out of in two minutes. They will not seek help from those who do understand the matter for fear the latter should steal the idea.

An instance that came under my own cognisance will perhaps illustrate what I mean.

A friend of mine, a very able man, who had worked out several very remarkable inventions in connection with electricity, was working at one in which the armature of a powerful electromagnet was required to detach itself from its poles very quickly. He could not persuade the armature to let go without a touch of the hand, which, of course, it would not get in actual work. I believe he had been working round this difficulty for some weeks, when I happened to call, and he confided his trouble to me. He had previously been asking me, by letter, what iron we used for electromagnets and so on, but my replies had brought him no relief. On seeing the apparatus at work, the cause of the trouble was visible at once. He closed his magnetic circuit each time that his armature came up to the poles, the naked iron of the armature bearing on the naked iron of the poles, with the usual result. As your readers all know, the insertion of a slip of paper between the armature and the poles, thereby breaking the magnetic circuit, overcame the difficulty, and I heard no more of that trouble. In many cases, however, inventors who are not masters of the subject they are

Digitized by Google

working on get over their difficulties by adding to the apparatus. It often happens that the addition introduces a fresh difficulty quite unforeseen, and this is overcome by a further addition and so on, until the apparatus, when it finally leaves the inventors' hands, is too complicated for any ordinary human being to understand, much less to buy.

Max Adeler's clever sketch of the inventor of the carbolic mat, who had met with such a series of difficulties, is by no means so much of an exaggeration as it might seem.

The carbolic mat was to prevent the communication of disease, only its odour was unbearable, therefore a nosebag containing a special preparation was added.

The special preparation, however, evaporated, therefore two bottles of the preparation were given. These, however, if carried in the coat-tail pocket and subjected to the concussion of falling down backwards, were liable to explode, therefore a life policy in the inventors' own company was given to all buyers of the carbolic mat at special rates.

The other class of inventors who never finish are those who are always improving, but never completing for the market. No sooner does one of these men bring his idea up to a certain stage, than right in front of him appears a better one. Perhaps it is a cheaper method of construction, perhaps a better method of working. In either case the original plan is dropped forthwith, and a fresh start made on the improvement, that being abandoned in its turn for a further improvement, and so on.

An accountant related to me an experience of this kind some time since. An inventor had produced a very clever machine for making brushes. A company was formed, plenty of working capital put in, and everybody was enthusiastic; and yet that company never paid a dividend, and finally liquidated, because they were always seeking to improve the machine, and orders had to wait till the improvements were complete. As originally arranged, my informant assured me, the company should have done very well indeed. It was not heavily loaded with dead capital or promotion money, and its working expenses were small; while the cost of production by the original machine left a margin for a splendid profit, and orders were plentiful. Yet the company was wrecked because no sooner was the plant down than the inventor saw his way to reducing the cost still further by another machine, and he so dazzled the eyes of his directors, who presumably were not business men, that they actually joined with him in holding the business back, losing present profits in order to secure the additional profit that would come when the new machine was made, and this process, I believe, was repeated till the company wound up.

SINGLE-STROKE MAGNETO BELL.

Mr. A. A. Campbell-Swinton has made a speciality of magneto-electric bells, constructed exactly as a dynamo and motor. A small fully-formed magneto-dynamo machine is used for the transmitter, and a small motor in the bell

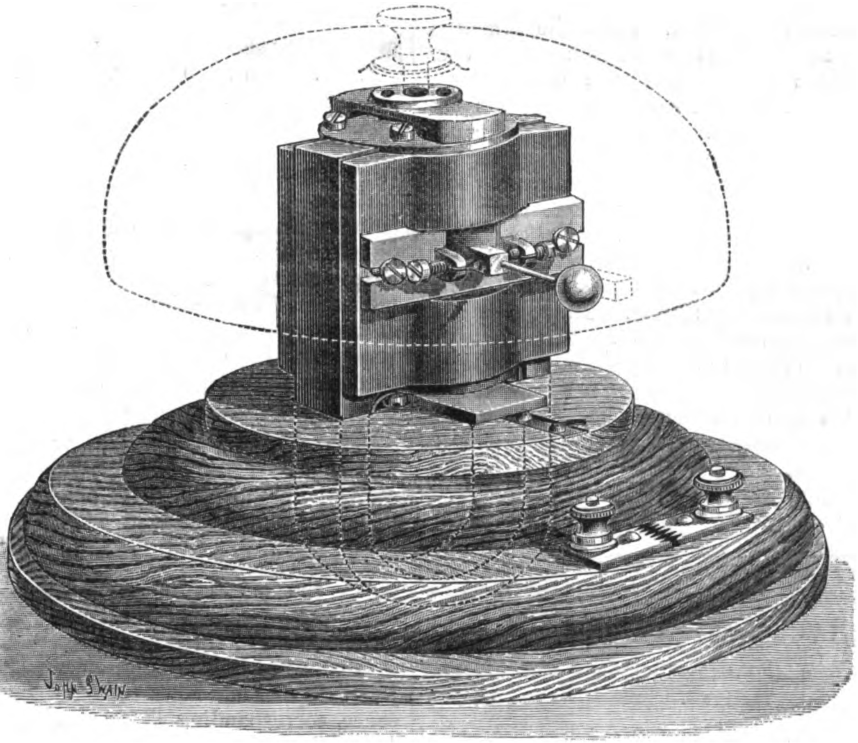

Fig. 1.—Cox-Walker Swinton Single-Stroke Magneto Electric Bell.

itself. We illustrate herewith the latest form of single-stroke bell, which is very compact and well-arranged in its details, and admirably adapted for use for railway or col-

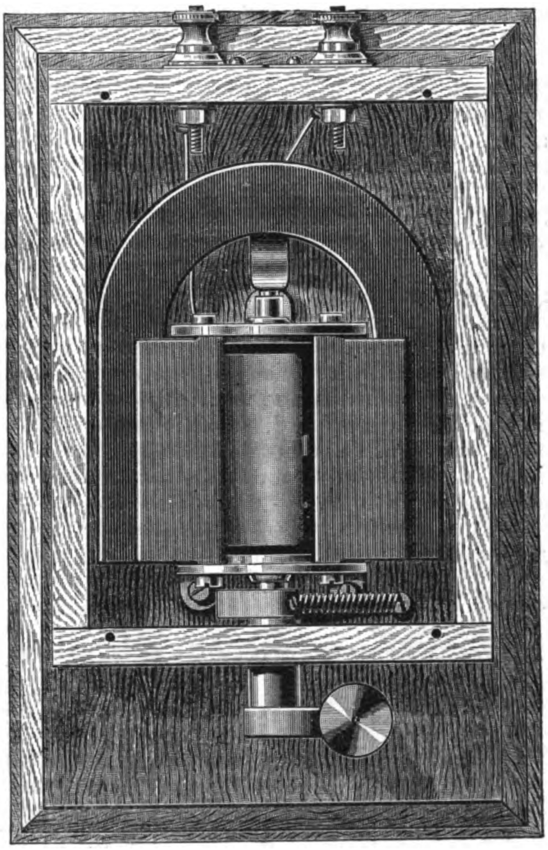

Fig. 2.—Transmitter for Magneto Bell.

liery signalling, or other use where extreme simplicity and the absence of batteries is desirable.

In these bells a strong compound magnet is fixed firmly in a suitable position, and a small Siemens-wound H arma-

Digitized by Google

ture, suitably wound for the purpose required, is centred between the poles. This arrangement is the same for both generator and receiver, the position of the magnets only being different. The armature of the generator has a lever and finger-knob attached to it by which the armature can be rapidly jerked by pressure of the finger; strong spring rings it back to position.

The bell itself is shown in Fig. 1. Here the armature acts as a motor, with a strong jerk, when an instantaneous current is sent. The armature has a small hammer attached, which strikes against a projection cast on the inner surface of the dome or bell. Fig. 2 shows the transmitter. One stroke on the knob makes one ring on the bell, which may thus be used for signalling purposes. The bell will ring through any ordinary line resistance, ringing through up to 1,000 ohms as now wound.

These magneto single-stroke bells have been adopted upon the Cambrian Railway, where they were tested for some time with very satisfactory results. They have also been introduced with great success at several collieries in the North of England. There is very little doubt that these bells will be introduced for many ordinary purposes as well as for signalling, as the entire absence of batteries and the attendant trouble is an immense point in their favour. The bells can be seen working in action, and suitable for various purposes, at Mr. Campbell-Swinton's offices, 66, Victoria-street, Westminster.

THE EFFICIENCY OF METHODS OF ARTIFICIAL ILLUMINATION.*

BY EDWARD L. NICHOLS, PROF. OF PHYSICS IN CORNELL UNIVERSITY.

(Continued from page 316.)

The second method pursued by Mr. Merritt was intended rather as a check upon the results already obtained than in the expectation of gaining further data. The rays of the lamp were allowed to fall upon the face of a delicate thermopile placed at a distance of about 60c.m. The thermopile was in circuit with a low-resistance galvanometer of the well-known "tripod pattern" of Sir William Thomson. The deflection of the galvanometer was taken as a measure of the total radiation, luminous and non-luminous, which fell upon the face of the pile. A cell containing a solution of alum was now interposed, and the reduction in the galvanometer noted. The arrangement of this apparatus is shown in Fig. 2.

An aqueous solution of alum fulfils much more nearly the desired condition of complete opacity to "dark heat" and complete transparency to the rays of the visible spectrum than any other substance, but a certain small percentage of the longer wave-length will pass through such a bath, and a considerably larger percentage of light giving rays will be cut off by it. The proper corrections are, however, easily determinable, and when, in this case, they had been determined and applied, the ratio of total to luminous radiation was found to be in gratifying agreement with the efficiency obtained by the calorimetric method already described. *See* Table II.

TABLE II.

Lamp B.—An Edison 16-c.p. Lamp. Resistance = 249 ohms.

12·2	25·2	0·2	0·20	0·008	1·00
13·4	30·8	0·5	0·41	·013	0·84
15·0	40·4	1·3	0·75	·018	0·57
16·4	53·2	4·1	2·03	·038	0·50

It is interesting to compare these results with some obtained by still another method. Captain Abney and Colonel Festing, in the *Proceedings* of the Royal Society, have described a series of elaborate studies of the radiation of the incandescent lamp. The portion of their very important investigation which has a bearing upon the efficiency deals with the exploration of the spectrum of the lamp, under various degrees of incandescence, by means of an exceedingly sensitive thermopile. The energy of the visible spectrum of most sources of light is so minute that it has generally been deemed impracticable to measure it in this way. Captain Abney and his co-worker have, nevertheless, secured measurements covering not only the extensive regions of the so-called heat spectrum lying inside the red, but also the shorter wave-lengths which constitute the visible spectrum. Their results are shown graphically in Fig. 3.

One of the British Electric Company's lamps was subjected to measurement in six different states of incandescence, corresponding to 33·6, 60·2, 93·8, 116·4, 130·8, and 150·5 watts respectively. The curves show the intensity of each wave-length of the spectrum when the above amounts of energy were expended in the filament, and the total area enclosed by each curve affords a relative measure of the total radiation of the lamps in the state of incandescence in question. I have added to this diagram, of which, in other respects, Fig. 3 is a faithful reproduction, the vertical line lying between scale divisions 5 and 6 of their scale. This line marks the boundary between the visible and invisible spectrum. The entire area to the right of that line represents the energy wasted in the lamp; the much smaller area to the left comprises the light-giving rays. The ratio of the entire area of each curve to that portion lying within the boundaries of the visible spectrum gives us the efficiency of the lamp for the state of incandescence of the expenditure of the number of watts for which the curve is drawn. This ratio increases from a very small value with the brightness of the lamp.

I have made approximate integrations of the areas embraced by the curves for 150·5 and 130·8 watts, respectively, for the purpose of comparing the efficiency thus calculated with the results obtained by Mr. Merritt. The ratios are:

Watts.	Efficiency.
150·5	5·55 per cent.
130·8	5·15 „

The corresponding values for lower states of incandescence are all smaller than the above.

It will be seen that these results are in complete agreement with those obtained with the glass calorimeter and by the method of Melloni. We have, indeed, reason to feel that our knowledge of the efficiency of the incandescent lamp, in so far as it can be expressed by the ratio of luminous to total radiation, is well grounded, and that we are in position to determine the light-giving efficiency of any type of glowlamp in any condition of incandescence with the same certainty and exactness which is attainable in the measurement of other machines for the transformation of energy.

The average net efficiency of the incandescent lamps of to-day, for we may have untouched for the present the efficiency of the process by which the latent energy of fuel from which the current is generated has been converted into electrical energy, is rather below than above 5 per cent., and since the ratio of total radiation to light-giving radiation increases but slowly as the temperature of the radia-

ting body rises, the efficiency is not likely to be increased in any very marked degree until we shall have learned how to suppress altogether these long wave-lengths which yield us dark heat, and are able to limit the vibrations of our source of light to that brief octave which comprises the wave-lengths, to which alone the human retina responds.

Whether this great step is to be made by robbing the glow-worm and firefly of their secret, as has been suggested in a recent address by the director of the Sibley College of Mechanical Engineering,* or by development along the lines sketched the other evening by Prof. Brackett at the meeting of the Electric Club, or by the application of some principle as yet unconceived, we know not. Meantime, we have in the methods of artificial lighting of to-day abundant material for study and investigation.

The investigation of the efficiency of the arc light, by the methods under consideration, is a much more difficult matter than the same determination in the case of the incandescent lamp. The radiating surface of the latter is very nearly of the same temperature throughout, and the ratio of total radiation to luminous radiation, obtained for the bundle of rays sent out in a single direction, gives us at once the measure of the efficiency. In the arc we have, however, a light-giving area of great brilliancy in the immediate neighbourhood of the arc, and the temperature of the carbon falls with great rapidity from the maximum at the point and crater to regions which are at a red heat.

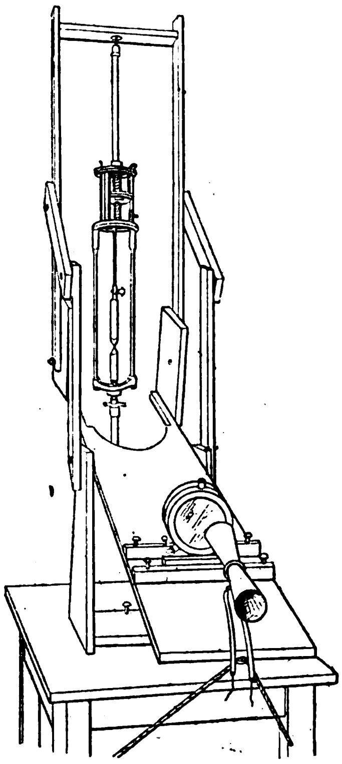

FIG. 4.

The entire light-giving area is included between the line surrounding the positive carbon, which is at red heat, and the corresponding line upon the negative carbon. Between these two lines we pass rapidly through regions the light from which varies with the degree of incandescence by insensible gradations from that which a red-hot surface is capable of emitting, to that coming from carbon at the highest temperature which that substance can be made to assume. Now, the curve of distribution of c.p. taken in a vertical plane is, as we all know, a very peculiar one, and if we place our thermopile with alum cell interposed to measure the energy of the light-giving rays, the amount of radiation received upon the face of the pile will greatly depend upon the position in which the apparatus is set up. At an angle of 45deg. or 50deg. below the horizontal plane, for instance, the amount indicated will be five or six times greater than in the horizontal plane. Now, the surface of total radiation is much larger than that from which the light-giving rays emanate. It includes, in addition to the incandescent surfaces near the arc, all those portions of the carbons which are heated by conduction or by the current.

The amount of heat radiated from regions which are below the red heat is very considerable, and forms an important factor in the determination of the efficiency. Were the distribution of total radiation in the vertical plane identical with that of the light-giving rays, the measurement of their ratio with the axis of the thermopile in any plane which passes through the arc would give us the efficiency of the lamp; but the curve of distribution of total radiation is not the same as that of candle-power, and the ratio in question is a function of the plane which the axis of the pile makes with the horizon. It becomes necessary, therefore, to make an exploration of the entire zone through which the lamp sends out rays, determining the ratio of total to luminous radiation for each angle, and then to integrate the results. Such an investigation is now in progress under my direction, and H. Nakano, who is carrying on the experiments, has reached some exceedingly interesting results. The research will soon be ready for publication in its complete form, and it will afford us much more definite data concerning the radiations of the electric arc than we now possess. It will not be out of place even now to say a word concerning the method which is being employed and the general character of the results already obtained.

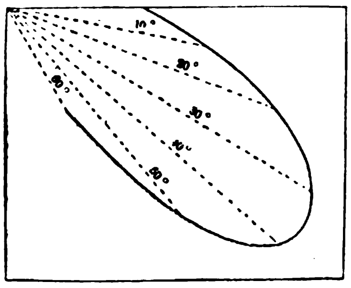

FIG. 5.

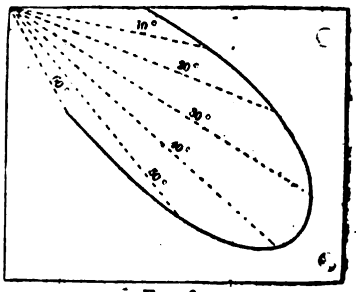

FIG. 6.

The first measurements were made by the second method employed by Mr. Merritt, the thermopile in the horizontal plane. The lamp subjected to measurement was of the long arc type, with 9 amperes of current and 45 volts. The efficiency in this plane was found to be surprisingly small. It was found, moreover, to vary in marked degree with the diameter of the carbons used, increasing as the diameter decreased to the point at which the carbons were rendered hot by the current, when, as might be expected, it fell off again.

The lamp was then mounted in a frame which also carried the thermopile and alum bath, and which was so constructed that measurements could be made at any desired angle. All necessary changes of angle could be made without varying the distance from the arc to the face of the pile, or the relation of the alum bath to the latter. By means of this apparatus, which is shown in Fig. 4, it has been found possible to determine the ratio of total to luminous radiation throughout the zone of radiation of the lamp, and to plot the curve of distribution of each.

Without entering into the details of an incompleted research, I may indicate the general character of the results by means of a diagram. The curves shown in Figs. 5 and 6 are those relating to a "long arc" lamp, with carbons ·45in. in diameter. They represent respectively the distribution of luminous and total radiation emanating from the lamp. The radii show the positions for which measurements were taken; distances measured along these lines from the origin to each curve give the relative intensities of light-giving and total heat energy in each position.

(To be continued.)

* "The second of these greatest of inventors is he who will teach us the source of the beautiful soft-beaming light of the firefly and glow-worm, and will show us how to produce this singular illuminant, and to apply it with success practically and commercially. This wonderful light, free from heat and from consequent loss of energy, is nature's substitute for the crude and extravagantly wasteful lights of which we have, through so many years, been foolishly boasting. The dynamo-electrical engineer has nearly solved this problem. Let us hope that it may be soon fully solved, and by one of those among our own colleagues who are now so earnestly working in this field, and that we may all live to see him steal the glow-worm's light, and to see the approaching days of Vril predicted so long ago by Lord Lytton."—ROBERT H. THURSTON (*Transactions of the American Society of Mechanical Engineers, 1881, p. 22*).

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

DONNER UND BLITZEN.

Those who attended the last meeting of the Institution expected a grand display of fireworks—verbal and actual—and were not disappointed. When Prof. Lodge enters upon the warpath some hard knocks are sure to be given, for he has the eminent quality of going straight at his object. Circumlocution is outside his idiosyncrasies altogether. He gets his nail into the wood, and drives it home with a sledgehammer—no puny or flimsy made-to-be-sold hammers for him. Usually, the sledgehammer comes down fair and square, leaving no possibility of uncertainty as to its action, but occasionally it does miss its object, or make a slanting stroke. One such example we might cite in a recent controversy on "fans." Another will be found, it may be, in the dogmatic assertions in the paper read before the Institution. Prof. Lodge is one of the ablest of the younger generation of professors, and has managed to cast aside many of the prejudices and failings of mere bookmen, but when he, in his own mind, sees a thing clearly, he is prone to assert that "it is so," "it cannot be otherwise," or in the words of the paper, "nor do I believe they are at all attackable from the side of theory." Just as Prof. Lodge speaks to the point, so we are inclined to do, and to say that this belief is not in accordance with a true scientific desire to arrive at the whole truth. Prof. Lodge, in fact, limits his theorists to a dozen men or so whose theories coincide with his own, and does not include among theorists those whose opinions he and those who agree with him term heterodoxical. It is this passion for dogmatic assertion that we wish to combat. The history of scientific progress shows the weakness to have existed in all ages of scientific investigation, and yet every generation has seen new theories taking the place of the old. If Prof. Lodge retorts that his reference is solely to facts, then we say theory has nothing to do with the matter. A fact is a fact all the world over, and does not want nor can it be controverted by theory. He tells us that a discharge by means of a pre-arranged path, "a steady strain," and one by means of "an impulsive rush," act differently, and he appeals to experimental proof to confirm his statement. No one disputes the facts arising from his experiments. There they are for all to see and to obtain at will. This is altogether a different question from possibility of being attacked by theory. Prof. Lodge practically says that from the time of Franklin to that of Faraday, and till his lectures at the Society of Arts last year, only one phase of the question had been considered. He points out another phase, and having discussed it, and made certain conclusions, claims finality. How does he know that an unborn Prof. Lodge may not in twenty-five years add another phase

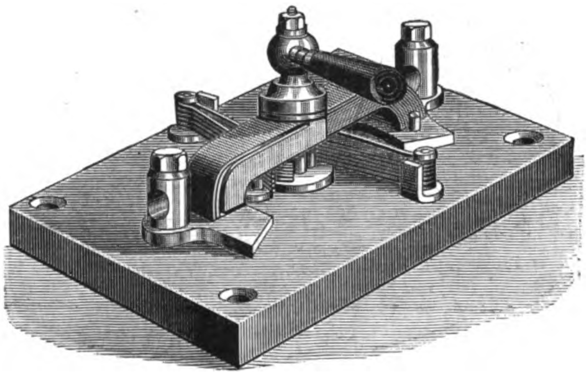
Digitized by Google

overlooked and unconsidered by the present holder of the title? If we misinterpret the position, we are sorry, but that an effort has been made to support the conclusions stated without always considering that the same "extracts" may bear two interpretations is plain. An example is cited from a writer in *Nature*, who is mildly reproved as giving "contradictory advice." Another reader than Prof. Lodge *may* be unable to see the contradictions. Fish were killed in a fishpond, from the effects of lightning—a rod having its end in the pond. The writer of the note asks, "When will people learn to make proper earth connections?" Prof. Lodge says, "Before an accident, the pond would be pointed out as an excellent earth, *as indeed it most likely was*." The italics are ours. We, in our ignorance, thought the common teaching to be that there are ponds and ponds, or water and water. Does not Anderson in his book, now some years old, point out that a rod led to earth in a pool of water in a rock probably does not make a good earth, and just so an artificial pond or a natural pond of certain character has long been held to be bad earth. Suppose the pond of the writer in *Nature* to have been an artificial pond, well concreted and cemented, it would not be good earth, and no accepted authority would so advise. Prof. Lodge does not seem to know the nature of this particular pond, neither do we, and the matter is referred to only to show that there may be no contradiction in the advice from "advisers *re* earth for rods" when the whole facts are known.

Having had our say as to the inadvisability of dogmatising over theories, and the weakness in attempting to find facts to suit theories, we must join heartily in thanking Prof. Lodge for his great services in calling attention to the present state of electrical knowledge as regards protection from lightning. He has pointed out dangers hitherto ignored; he has, without mercy it may be, attempted to wake those in authority to a due sense of their responsibility. He has shown sufficient reasons for the report of the L. R. C. to be immediately withdrawn, for the conference to be reconstituted, and for another report to be issued, with suggestions, after taking into consideration the new light thrown upon the subject. Prof. Lodge gives the basis of the work of such a conference in the summary of statements at the end of his paper. No doubt the discussion upon the paper will throw further light upon the question, and our suggestion of a new committee find favour with those interested in the matter. It is quite certain that agreement will not be obtained at these public meetings, but the advisers of the Government will be bound to pay attention to the tendency of modern scientific thought, though without further and more definite assistance they will be unable to decide as to what is best. Architects who have the designing of private mansions, and have to arrange for protection, will soon be in doubt as to what to do, how to do it, or how to go to work. On the one side, they know about copper, while on the other, they are told "iron" is better. We only see a way out of the difficulty by means of a conference and an authoritative report. Will the Institution take action?

MAIN SWITCH.

The evolution of the main switch is proceeding towards perfection, and the latest development, embodying the fulfilment of the most recent requirements, is furnished by Messrs. Woodhouse and Rawson in the main switch we illustrate.



Woodhouse and Rawson Sudden-Break Main Switch.

The appearance of the switch, which is a large one, is well shown, as well as the various improvements therein. To briefly describe it: the base is of slate; the handle is loose on the cross bar, which it turns with a pin, ensuring quick break; there is a small "buffer spring" at each side to break the force of the break; the spring is a strong steel one of several wires, to make the break strong; the cross piece is very massive, and is constructed in numerous plates, ensuring good contact. The switch is provided with large contact screws for large cables, and is specially suitable for central stations, or large main wires where heavy currents have to be carried. The switch is well designed and well made, and should command an extensive sale.

ON LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS.*

BY DR. OLIVER LODGE, F.R.S., MEMBER.

Introduction.

About this time last year I delivered two lectures to the Society of Arts on the subject of "Lightning Conductors," in pursuance of a bequest made to the society in memory of the late Dr. Mann. In those lectures I abstained, as far as possible, from practical recipes, and from anything like authoritative advice, contenting myself with calling attention to certain aspects of the subject which had been overlooked. I ventured to imply that none of the older electricians had any notion of the real conditions of the problem; that they all, from Franklin to Faraday, and down to the present day, treated it as a much easier matter than, in fact, it is; and that there had been very little real progress in this particular department since the time of Franklin.

Recent advances in electrical theory made it easy for me to see further into the matter than the far greater men of the past had had any chance of doing; and a few very simple and easy experiments soon brought the conditions of the problem clearly before me.

It was these conditions upon which I laid emphasis in my lectures to the Society of Arts. Any practical outcome I left to a later period, and very likely to other hands. The first requisite seem to be to grasp the conditions of the problem as illuminated by theory; the second, to carry out practical reform in the light of a large experience.

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

Such few practical recipes as I did surreptitiously introduce I fully expected to hear criticised, nor did I lay any stress on them at the time. (I may say, however, that I have seen no occasion since to importantly modify any of them, and that my position in respect of these practical hints is stronger now than it was then, inasmuch as I find that the large experience of the Belgian electricians, who have given more attention to this subject than perhaps any other school, has led them to recommend in recent years almost precisely the same methods of protection as those I advocated : their views being acquired almost entirely by practical experience and scarcely at all by theory.)

The theoretical and experimental portions of my lectures were, however, matter of serious consideration with me, and nothing was set down under these heads but that of which I was absolutely sure. These portions have by all pure physicists been, so far as I know, universally accepted ; as, indeed, they contain nothing but what anyone of them could have easily arrived at had he happened to give sufficient thought and attention to the subject. They have not been attacked, nor do I believe they are at all attackable from the side of theory.

But from the side of experience an attack has come, and, strange to say, it has been directed, not at the few practical suggestions, which might be expected to be vulnerable on that side, but at the theoretical and purely scientific portions.

At the Bath meeting of the British Association, the then President of Section G, speaking in the light of a most gigantic experience—a personal acquaintance with over half a million conductors—led a most good-humoured attack against the doctrine of my lectures, and, exercising his well-known rhetorical and oratorical powers, succeeded probably in impressing the general bulk of the audience with the belief that he had, on the whole, the best of the battle; though, at the same time, I expect they were in a state of utter bewilderment as to what the conflict had been all about, and where the difference " 'twixt tweedledum and tweedledee " precisely lay. The battle was, however, admittedly a drawn one, and at its close Mr. Preece magnanimously offered me another field, with an audience of an altogether different calibre to the general public of Bath, by getting your secretary to invite me to read a paper before this Institution. Thus much by way of historical note and introduction. Now for the scientific portion of the paper.

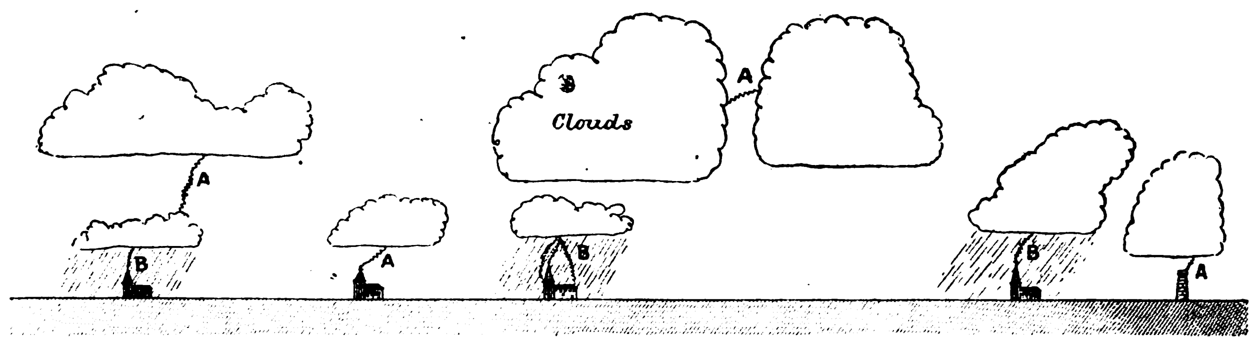
I begin by running over some of the conclusions at which I arrived, and proceed to re-establish and demonstrate their correctness either by theory or by fresh experiment, whichever may seem the most simple and satisfactory under the special circumstances.

Two Main Cases of Lightning Flash.

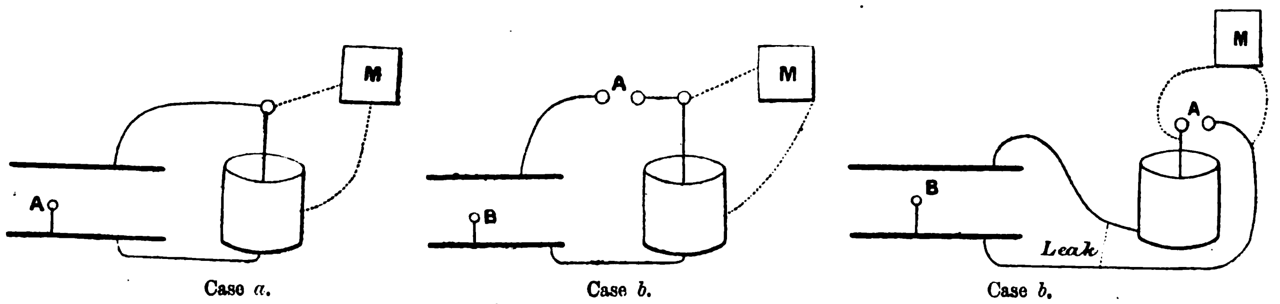
1. All discharge is virtually that of a Leyden jar. There are always two conductors separated by dielectric, and the discharge is a breaking down of the dielectric at its thinnest or weakest place. In a thunderstorm the charged conductors are obvious, being either two clouds, or else a cloud and earth, and the dielectric is the air between.

2. It must sometimes happen, when one cloud discharges into another, that the potential of this other is suddenly raised high enough to cause it to discharge into the earth, even though no strain previously existed in the air between it and earth. The same thing may happen in various other ways when two clouds spark into each other, as indicated by the diagrams (Fig. 1).

3. There are, therefore, two main cases—(*a*) when the strain in the dieletric near the earth has been of gradual growth, in which case the path of discharge will be prepared inductively beforehand; (*b*) when the strain arises so suddenly that there is no time for any pre-arranged path. The first I call "steady strain"; the second, "impulsive rush." It is most important to recognise these two cases, and to understand the extremely different conditions attending the two. The first case only was ever contemplated by the older electricians ; in fact, so far as I know, it was my experiments last year which first called attention to the other case.



Case *a*. Case *b*. Case *b*.



Case *a*. Case *b*. Case *b*.

FIGS. 1 AND 2.

Figs. 1 and 2 represent the same conditions as they may occur in nature, and as they can be arranged artificially. Case *a* in each figure is the steady-strain case. The others are varieties of the impulsive rush, when a spark at A precipitates a spark at BD ; the place where B occurs having been subjected to no preliminary strain. Clouds compared to coatings of jars ; spaces between them compared to glass or other insulating space. The position of the charging machine, M, is indicated in Fig. 1 for convenience. The leak or imperfect conductor in the second case *b* of Fig. 1 is needful in order that the jar may charge. It takes no part in the discharge. Its place is taken in Fig. 2 by the rain-shower. In case *b* the rain-shower or leak are permissable, but unnecessary.

Conditions of Protection and of being Struck, under the Circumstances of each Case.

4. I will now illustrate experimentally* the conditions under which discharge occurs in each of these two main cases ; and I will take first the case of steady strain, or case *a*. This insulated sheet of tin plate is supported horizontally a foot or two above another plate lying on the table, and it is electrified by a Wimshurst machine. It represents a charged cloud hovering over the land, the lower plate representing the earth. Between the two I can erect buildings, and lightning-conductors terminated in various ways. The typical terminals which I will here use to illustrate the conditions are four—viz., a large knob, or, as I shall call it, a "dome"; a small knob, which I shall call "knob"; a sharp point ; and a gas flame, to represent a chimney, or other furnace current of rarefied air. Putting the knob and the dome between the plates, we find the knob struck by preference, even though the dome stands at a much higher elevation. Introducing the point, we find it protects both, by a silent discharge, until it is lowered very considerably ; and that then several points may protect when one does not. Replacing the point by the flame, we find that it protects too, but not so efficiently as the point, and that it gets curiously beaten down and darkened in the act of protection. The point is not struck by a noisy flash until it is raised pretty close to the upper plate when it is struck ; but a

* The experiment was shown with a splendid machine most kindly brought over and erected for the purpose by Mr. Wimshurst himself, whom I cordially thank.

Digitized by Google

bunch of points is even then not easily struck, sometimes continuing to discharge with a constant fizz right up almost into the cloud.

5. Try the effect of a bad earth or other very high resistance interposed in the path of the conductor—say a capillary water tube or a bit of wet rag or a wet string. The violence of the spark is greatly lessened, and the sound is now gentle, but that which was struck before is still struck; resistance, so long as it be something short of infinite, makes no difference to the ease with which a given object is struck under the circumstances of this case 1. Insert the wet rag in path terminated by point, and it still protects, practically, as well as before. Insert it in path terminated by knob, and it gets struck at the same elevation as before. The fact is that the path of the disruptive discharge is all negotiated and prearranged in the air above, especially on the surface of any small conductor reared into this space, and the resistance which the flash may ultimately have to meet with in its passage to earth is a thing of subsequent consideration.

6. So much for the conditions attending case *a*, the steady strain. Now attend to case *b*, the impulsive rush. We shall find everything very different. Alter the connection so that a charged Leyden jar must, when it discharges, discharge direct into the upper insulated tin plate, and thence overflow to the ground if it is able to raise the potential high enough. If the plate is too far above ground for a flash to occur, the Leyden jar does not completely discharge; it only produces a number of fizzes and spits, and the greater part of its charge remains in it. But when the upper plate is within sparking distance of the ground (and the sparking distance under these circumstances is surprisingly great by reason of the impetus with which the electricity rushes into the top plate), then the jar discharges completely, and we have a violent crack both between the knobs of its discharger and in the air gap between the two plates, which is in the path of the discharge; the arrangement being really two condensers in series, but only one charge. The only object of the Leyden jar in case *a* is to give more body to the flash. In case *b* the Leyden jar, or its equivalent capacity, is essential.

7. Putting the dome and the knob between the plates arranged as in case *b*, we find that one gets struck as easily as the other; the knob has now no advantage—whichever is the higher, that gets struck, without reference to other considerations. Introducing the point also, we find precisely the same is true for it; its protective virtue, so much insisted on by the older electricians (among whom I suppose I am right in reckoning my chief antagonist), is entirely non-existent. It gets struck no more easily, and no less easily, than the dome, and it gets struck by a flash of precisely the same noisy character as the others get struck with. A bunch of points acts in exactly the same way. A comb of 24 needle-points protects nothing, and gets struck just the same as anything else.

8. Now introduce the flame, and one notices a marked difference. In case *a* it protected less well than the point, but it was not struck noisily any more than the point was. In the present case it gets struck with violence, and it gets struck much more easily than anything else. Adjust dome and knob and point at about the same level, and they get struck, one or other, at random. Adjust the flame a great deal lower, and it protects them all, not by silent discharge, but by getting struck itself instead. "Protection," however, is in this case not the word to use. The flame better represents a chimney requiring protection, while the point corresponds to the pointed terminal of a lightning-conductor raised a good deal higher with the intention of protecting it. Protect it, it does not, however; the flash strikes down the column of hot air and through the flame, while it avoids the more lofty pointed terminal altogether. Bring a point or a knob or anything into the column of hot air above the flame: then it gets struck easily enough, and protects the flame, but not if it is on one side of the hot-air column. The experiment has an obvious moral in relation to the protection of chimneys. It suggests that the continental plan of a bar or arch across the mouth of the chimney may, after all, be justified.

9. Try the effect of resistance in the path of the discharger *now*, and we find it is altogether different to what it was in case *a*. In case *b* things get struck according to their height, independent of the shape of their terminals, but not independent of their resistances. Interpose a wet rag in the path of any one, and that one fails to be struck; it is not struck, and it fails to protect the others from being struck, even though it be reared up till it touches the top plate. The top plate need not, therefore, be insulated at all carefully for this case *b* experiment.

Imitation of Lightning.

10. Now let us modify case *b* by making the top plate a sieve full of water, so as to get the flashes in a shower of rain. One cannot well try case 1 in a rain shower; the plate would be discharged too rapidly and continuously by the water-drops for its potential to fully rise. But in case 2 the top plate is not necessarily charged at all until the rush comes, and so the rain shower does no harm. Flashes in the rain can be got of surprising length and shape, for they make use of the water-drops as stepping-stones. By adding salt to the water they become longer still, but there is no need thus to improve its conductivity for what I want to show. Notice how the flash contorts itself, taking sometimes extraordinary paths as it jumps from drop to drop, but yet exhibiting its instantaneous character by showing the drops as stationary in its illumination.

11. Remove the things standing on earth-plate just beyond fair striking distance, and what do we see? Appearances precisely like those which are observed in many lightning photographs. A crowd of violet discharges fill the rainy air—forks and branch and multiple flashes, not very bright or very noisy, but extraordinarily numerous, and striking on innumerable places at once. A rot is set up in this air at every attempt of the jar to discharge, exactly as happens in one of the most striking of the photographs belonging to the Royal Meteorological Society. Masts and spars and deck and ocean may be simultaneously struck by these interesting flashes; and, though they do not here appear very violent, yet I expect that on the larger scale of Nature they are not very safe, and may easily have a heating effect sufficient to ignite bodies. These experimental ones are able to ignite gas in the midst of the rain.

12. While we have this arrangement at work we may as well try an interesting little experiment on what happens when lightning reaches water. The rain-water has here been collected in a zinc tray some 3in. deep, and by bringing a knob from the top plate, some 6in. or so above the water, a flash strikes it. It prefers to strike anything metallic if it can, but if there is nothing else within reach, it will strike the water. On reaching the water the flash forks out and ramifies in all directions in a crow-foot pattern, giving the same sort of appearance, only coarser, as that obtained by Mr. J. Brown by taking sparks on to a photographic dry plate and then developing. Bring the knob nearer and nearer, the same thing happens, until the water is touched by the knob, and even after it is submerged. But as soon as the metallic conductor is submerged the ramifications get less and less vigorous, and when a sufficient surface is immersed they cease. I have never seen these ramifications spread of themselves *below* the surface of the water. They appear to me to keep entirely to the surface. But I have not yet finished investigating these appearances.

13. Immersing a half-full beaker in the water, sparks can be got to the water inside it, though they prefer to curl round and go outside. The noise the sparks make when they go inside is a curious one, and sounds as if the glass cracked each time, but it does not. If the glass is moist, a brush cascade round its edge can be seen in the dark. If it be dry, the water inside gets charged, and fizzes audibly back to the knob for a second or so after the spark has ceased, a dimple being visible in the water below the knob.

14. Live things in the struck water—worms, flies, fish, etc.—will most certainly get struck; but so they do under far less violent disturbances than what they would here be subject to. There is nothing surprising in the fish of a pond or lake being killed by a flash of lightning; and it has often happened. When H.M.S. "Conway" was struck many years ago, and protected by its lightning-conductors, it is related that the sea-water was seen to be luminous on all sides of the ship. This is exactly the effect I now imitate.

15. There is one more experiment on discharge in water which I have just tried, and which it is interesting to show.* I take a pointed rod, and, protecting it by a glass tube, immerse its point under water in a beaker containing a plate connected to the other coat of the jar, and pass a spark. With the point negative, there is a bright glow region round it every time, but the discharge is quiet. With the point positive, the flash is of a dazzling white, and is accompanied by a great deal of noise and violence, threatening to smash the Leyden jar, and throwing down the copper plate towards the bottom of the beaker with fury.

Oscillatory Character of Lightning.

16. Before leaving the outdoor department of our subject, I must say a few words on one branch of it concerning which there is evidently considerable uncertainty and haziness abroad—I mean the oscillatory character of a lightning flash. That a Leyden jar discharge is usually oscillatory must now be regarded as so extravagantly proved that any doubts that may have existed on the subject must surely by this time be cleared away, at least for the case where the discharge has to utilise a wire circuit. But perhaps it is still doubted for the case when a jar overflows its edge, or, still more, when it merely sparks through its own dielectric, straight between the coatings. Now, as I have insisted all along, a lightning flash is a spark through the dielectric of a jar whose two coatings are either two clouds, or else cloud and earth. Hence, if any importance is attached to the fact (as I believe it) that lightning flashes are oscillatory, it is necessary to prove it for a Leyden jar sparking direct between its coatings, especially when the coatings are not very close together.

* This experiment was not shown at the meeting because in trying it over in the afternoon the protecting glass tube was electrically broken.

Digitized by Google

17. The reason I do attach importance to the oscillatory character of a discharge is because I have worked out the quantitative behaviour of conductors on that aspect of the matter; and though, as Prof. Fitzgerald said at Bath, everything would hold just as well for a single oscillation—viz., one violent rise and decay of current (which without any doubt must accompany a lightning stroke or any other quick discharge whatever)—if rapid enough, yet the rapidity of such a charge as this does not seem to me probably at all sufficient to account for some of the effects. The rapidity of variation of current in that case would be directly connected with the total duration of the flash; and though we have evidence that it is very momentary, yet we have no evidence that it is so instantaneous (say a millionth of a second) as the semi-period of one of the oscillations may be, a dozen or more of which may accompany an entire flash. However, I admit, of course, that all I want is a tremendously rapid variation of current; and if I can be given this by one oscillation, the rest are unnecessary, and may be dispensed with.

18. When I speak of the oscillatory character of a flash, let it be understood once for all that I do not mean in the least such a thing as can be analysed by waggling the head. Flashes analysable by waggling the head must be multiple ones, and the interval of time between their constituents (which may be, say, the fiftieth of a second or thereabouts) is a long period compared with that of an oscillation such as I mean, bearing the same sort of ratio to it as a quarter of a century bears to an hour.

19. A direct experimental proof that lightning is oscillatory will be obtained when photographs of it are taken on a sensitive plate revolving 1,000 times a second. Something short of that speed would cause the image of the flash to blur, but that speed might be sufficient to analyse out the oscillations, when examined carefully with a magnifier, the focussing being good. Till then the easiest proof that it is oscillatory is a theoretical one, and it can be put in a few words.

20. Consider an air condenser with two coatings, each of area A, separated by the distance h, and let it burst its dielectric. It is well known that the discharge is oscillatory when the whole resistance met with by the discharge is anything less than a critical value.

$$R_0 = 2\sqrt{\left(\frac{L}{S}\right)}.$$

Now, attending only to the straight part of the discharge, and ignoring the current rushing up in the plates to the spark path, the self-induction of a straight conductor of length h and sectional radius a is very approximately $L = 2\,\mu\,h \log \frac{4h}{a}$.

The capacity of the discharged condenser is $S = \frac{KA}{4\pi h}$.

Hence the critical resistance which must not be exceeded is given by

$$R_0^2 = \frac{32\,\pi\,\mu\,h^2}{KA} \log \frac{4h}{a};$$

or

$$R_0 = 10\,\mu\,h\,\text{“}v\text{”}\sqrt{\left(\frac{1}{A}\log\frac{4h}{a}\right)}$$

$$= 300 \text{ ohms} \times \sqrt{\left(\frac{1}{A}\log\frac{4h}{a}\right)} \times h.$$

The important thing to notice in this value of $\sqrt{\frac{L}{S}}$ is that it is approximately proportional to the first power of h, the distance between the plates of the condenser.

21. Next consider the resistance of the discharge path. It, too, will be proportional to the length h, and it may be written $R_1\,h$, where R_1 is the resistance per unit length of the discharge path.

The condition for oscillation, then, is that this $R_1\,h$ shall be less than R_0; or *the resistance of unit length of the spark must be less than* 300 ohms $\times \sqrt{\left(\frac{1}{A}\log\frac{4h}{a}\right)}$.

22. The term under the square root will take different values according to circumstances, and it may be greater or less than 1 per metre. Ordinarily, however, it will be greater than 1 per metre, unless the area of charged surface is considerable. The important thing is the way in which h, the distance between the plates, enters into the expression. It does not come in very prominently at all, but so far as it does influence the result it permits the discharge to be oscillatory more easily when the plates are a good distance apart than when they are close together.

23. Take a couple of typical examples. First, a Leyden jar bursting its glass. A fine needle may be just put through the hole usually made in these cases, so we can take the sectional radius, a, as something like a tenth of a millimetre. The thickness of the glass may be two millimetres, hence $4^h/_a = 80$ or thereabouts, and the natural logarithm of this is about four. Suppose the area of coated surface is half a metre square, then the critical resistance which a metre of the spark must not exceed is 1,200 ohms, and so the two millimetres of it must not exceed 2·4 ohms. It is difficult to say whether this is or is not a large resistance for such a short spark, and hence it is difficult to be sure that such a spark is anything more than a mere one-directional discharge. To go into it more fully, the currents in the metal coatings would have to be considered. Next, take as example a cloud area at an elevation of one kilometre; and because a lightning discharge usually makes perforations of fair diameter, we may suppose a to be about a millimetre. (A widely erroneous estimate in this quantity makes but little difference in the result.) In such a case $4^h/_a = 4 \times 10^6$, and the logarithm of it is between 15 and 16. Hence the charged area may be 15 or 16 square metres without bringing down the square root term below 1 per metre; so the resistance of the whole flash may in that case be anything below 300,000 ohms without checking the oscillations. The discharged area may indeed be as much as 1,500 square metres without bringing the critical resistance which the flash must not exceed below 30,000 ohms, or 30 ohms per metre. Understand that "resistance" here does not mean impedance. It means true dissipation of energy resistence (section 25), and the current squared is so enormous (section 29) that the resistance-coefficient may be quite small. In another place (*Phil. Mag.*, August, 1888) I have shown reason for believing that the area of cloud discharged at any one flash is usually very moderate; and hence, on the whole, I consider it proved, so far as elementary theory can do it, that the lightning flash usually takes place under conditions favourable to oscillation.

24. And these oscillations are extremely rapid. The rapidity depends on the inverse geometric mean of L and S, and this is practically almost independent of h. Referring back to their values, we see that

$$LS = \frac{\mu K A}{2\pi} \log \frac{4h}{a};$$

and so the number of complete alternations per section is

$$\frac{\text{“}v\text{”}}{\sqrt{\left(2\pi A \log \frac{4h}{a}\right)}},$$

which, in the second example of section 23, with A as 100 square metres, becomes three million per second. If the discharged area were as great as 10,000 square metres, the rate of alternation would still be a third of a million per second.

(To be continued.)

THE TRANSMISSION OF POWER BY ELECTRICITY.*

BY FRANK J. SPRAGUE.

(*Concluded from page 313.*)

Referring to the equation (10) and substituting for m approximate value, 10·5, and for d its value, ·00000302705 we have:

$$v = \cdot 308\, l \sqrt{\frac{b\beta}{K+L}} \quad . \quad . \quad . \quad . \quad . \quad (17$$

Combining this with (13), we find that

$$E = \frac{\cdot 308\, l\, \lambda}{a\beta - \lambda} \sqrt{\frac{b\beta}{K+L}} \quad . \quad . \quad . \quad . \quad . \quad (18$$

We now see what influence the cost of copper has when the commercial efficiency is maintained constant, which is to vary the value of E as it increases, but only as the square root of such increase. It will be noticed also that a variation in K + L inversely affects E and v likewise as the square root.

It follows from the above that if we do not limit ourselves in the E.M.F. use, the cost per horse-power delivered exclusive of line erection is, for least cost and for a given commercial efficiency, absolutely independent of the distance.

We are met at times with the condition that the motor potential shall not be above a given amount, and from the formula,

$$E = \frac{\cdot 308\, l\, \lambda}{a\beta - \lambda} \sqrt{\frac{b\beta}{K+L}}$$

transposed to

$$\lambda = \frac{E\,a\,\beta}{\cdot 308\, l \sqrt{\frac{b\beta}{K+L}} + E} \quad . \quad . \quad . \quad . \quad (19)$$

* A lecture delivered before the Franklin Institute, November 12, 1888.

Digitized by Google

we find at once what the efficiency of the transmission must be with a given distance, and therefore whether it is worth while to attempt the operation. On the other hand, if, for example, we make our lower limit of commercial efficiency 50%, $a\beta$ = 80%, and β = 90%, we have a limiting equation.

$$E = \cdot 487 l \sqrt{\frac{b}{K+L}} \quad . \quad . \quad . \quad . \quad (20)$$

Since the circular mils. vary inversely with E v, the size, weight, and cost of the wire vary directly as the cost of the generating plant, which we have already seen from another formula. To get a matter-of-fact idea of this, I will assume some values, as follows :

Let K = \$45.00, L = \$20.00 (say for a water-power), M = \$50.00, and b = 25 cents for copper delivered on the ground.

Then we would have our formulæ for this particular case reduced to the following :

$$v = \frac{4 - 5\lambda}{5\lambda} E \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (21)$$

$$v = \cdot 0181 l \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (22)$$

$$E = \frac{\cdot 0905 \lambda}{4 - 5\lambda} l \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (23)$$

and

$$\lambda = \frac{4 E}{5 E + \cdot 0905 l} \quad . \quad . \quad . \quad . \quad . \quad (24)$$

which will give us the required elements of any single transmission under these conditions.

For example, suppose we wish to transmit 20,000ft. The fall of potential on the line could be 362 volts, and this is independent of the commercial efficiency. If this latter is made, say, 60 per cent., then E = 1,086 volts, and the potential at the terminals of the generator should be 1,448 volts. On the other hand, suppose we want to transmit a distance of 10,000ft. with a motor terminal potential of 800 volts, then λ = 65 per cent., and v = 181 volts.

We can, as I will soon show, make a graphic representation of these facts, which will save much labour and will give at a glance the various limitations.

Referring to the general equation, we can make, for various efficiences, a table as follows :

$$\lambda = 50\% \quad C = 2K + 2L + \tfrac{3}{4}(K+L) + M + \frac{P}{n}$$

$$55 \;,, \quad ,, \quad \tfrac{20}{11}K + \tfrac{20}{11}L + \tfrac{25}{44}(K+L) + M + \frac{P}{n}$$

$$60 \;,, \quad ,, \quad \tfrac{5}{3}K + \tfrac{5}{3}L + \tfrac{5}{12}(K+L) + M + \frac{P}{n}$$

$$65 \;,, \quad ,, \quad \tfrac{20}{13}K + \tfrac{20}{13}L + \tfrac{15}{52}(K+L) + M + \frac{P}{n}$$

$$70 \;,, \quad ,, \quad \tfrac{10}{7}K + \tfrac{10}{7}L + \tfrac{5}{28}(K+L) + M + \frac{P}{n}$$

$$75 \;,, \quad ,, \quad \tfrac{4}{3}K + \tfrac{4}{3}L + \tfrac{1}{12}(K+L) + M + \frac{P}{n}$$

$$80 \;,, \quad ,, \quad \tfrac{5}{4}K + \tfrac{5}{4}L + \quad o \quad + M + \frac{P}{n}$$

and substituting the assumed value of K, L, and M, we would have for the cost of transmission per horse-power delivered, exclusive of poles and line erection, and independently of the distance, the following table :

Efficiency, Per Cent.	Water-power.	Dynamo.	Wire.	Motor.	Electrical Total.	Water and Electrical.
50	\$40 00	\$90 00	\$48 75	\$50 00	\$188 75	\$228 75
55	36 36	81 81	36 94	50 00	168 75	205 11
60	33 33	75 00	27 08	50 00	152 08	185 41
65	30 77	69 23	18 75	50 00	137 98	168 75
70	28 57	64 28	11 61	50 00	125 89	154 46
75	26 67	60 00	5 42	50 00	115 42	142 09
80	24 00	56 25	—	50 00	106 25	130 25

The graphic representation of the facts which have been set forth, and the construction of an electrical reference table, which will at once show the necessary elements, is a simple matter.

We have the quotation,

$$E = \frac{\cdot 0905 \lambda}{4 - 5\lambda} l$$

Let us lay off on the axis of x the distance in feet, and on the axis of y the E.M.F. at the motor terminals.

Then for any value of λ the ratio of

$$\frac{E}{l}$$

is fixed, whatever the actual value, and we can draw the efficiency lines, O A, O B, etc., for

$$\lambda = 70\%, 60\%, \text{etc.},$$

which will, with the different values of l and E, give us any required information. This, however, is not yet in a convenient and general form, and we wish to get some general intersecting efficiency line. By an inspection of the diagram we see that if a general efficiency line can be drawn it must intersect the specific efficiency lines at such an angle that the intersected portions must be proportional to the differences of efficiencies. In other words, we must have the ratio

$$\frac{E}{\lambda}$$

for any particular value of E constant. Referring to the above equation and transposing, we have,

$$\frac{E}{\lambda} = \frac{5 E + \cdot 0905 l}{4} \quad . \quad . \quad . \quad . \quad . \quad (25)$$

It is evident that if we are to get this equation to give a straight line, we must make the condition

$$\frac{E}{\lambda}$$

a constant, r. Substituting we have—

$$\frac{E}{\lambda} = r$$

and

$$r = \frac{5 E + \cdot 0905 l}{4}$$

which will give in a series of parallel straight lines for various values of r and E corresponding.

Let $r = 1{,}000.$

Then we have— $E = 1{,}000\ \lambda$

and $E = \dfrac{4r - \cdot 0905 l}{5}$

when E and $\lambda = 0$, $4r = \cdot 0905 l$

or $l = 44{,}199,$

and when $l = 0,$

$E = 800$

and $\lambda = 80\%.$

Plotting this, we have a general efficiency line. Assuming another value for r, we get another straight line parallel to this, but one line is sufficient. It is, however, of prime importance. On it we lay off the efficiency percentages in equal increments, from 0 to 80%, and the chart which needs consist only of the axes of x and y, on which the E.M.F. and distance are laid off, and the efficiency intersecting line is ready for constant reference, and will give at a glance the graphic solution of all the ordinary elements of a transmission under the condition of least prime cost, and with the known efficiency of motors and dynamos. For example, suppose we wish to transmit a distance of 30,000ft. at a commercial efficiency of 60 per cent., what would be the required E.M.F. at the motor terminals? Drawing the efficiency line O B till it meets the ordinate erected at l = 30,000, we find the E.M.F. to be 1,620 volts. On the other hand, suppose we are limited to 1,000 volts at the motor, and must have an efficiency of 50 per cent., what would be the limiting distance? Reversing the above process, we find it to be 33,500ft. Suppose, again, that we must operate at a distance of 20,000ft., and are likewise limited to an E.M.F. of 800 volts at the motor, what would be the required efficiency? Through the intersection of the co-ordinates of E.M.F. and distance, we draw the efficiency line O H, and at its intersection find the efficiency to be about 55½ per cent. Such, then, is this method of graphic determination.

Commercial practice, however, may make it inadvisable to meet every phase of a transmission just as the theory may demand, and since in manufacture it may be advisable to build motors for three standard potentials—say, for 400, 800, and 1,200 volts, allowing the dynamo to be driven at the E.M.F. demanded by theory.

At the end of the paper is given a table of "illustrative rather than perfectly accurate" prices, but any English reader must take prices as they rule at the point where the machinery is to be used, and, in fact, construct estimates for each particular piece of work.

UNDERGROUND CONDUITS AND ELECTRICAL CONDUCTORS.*

BY JOHN B. VERITY (MEMBER).

(*Concluded from page 339.*)

It is underground conductors for high-tension currents that I propose now to deal with. A principal point for consideration is the necessity, or not, for lead sheathing where conduits or ducts are employed.

As to the durability of lead, much absurdity has been talked. It is notorious that lead pipes have been in the ground under all manner of

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

conditions, and at the end of long periods are still intact. There are no doubt certain clayey soils where lead has not much lasting power, but the lead may be materially preserved by coating it with coal tar, well tapeing it, and again soaking it in the coal tar or some such protective composition. Again, as Dr. W. von Siemens recently said in reply to Prof. Forbes' paper, the manner in which the lead covering is generally put on to such cables—viz., by heating the lead to the point of melting, and forming it in this condition round the cable, while passing through the press—there is no certainty of a uniform thickness, and it is very difficult to obtain a tube through which damp, in course of time, will not find an entrance, as air bubbles and impurities in the lead are liable to make the covering porous. A far better result is obtained by covering the insulated cable with a cold drawn lead tube, as the air which might still be contained in the lead block is compressed to a minimum.

A theory as to partial wasting of lead covering on cables is that it may occur from acid being present in the jute or fibrous insulation, or, again, that the petroleum residuums may set up a chemical action on the lead; but there has not been much evidence on these points. Manufacturers of lead-covered cables have admittedly put on too thin a coating of lead in the earlier days; this has been gradually increased, and with proper conditions and precautions there should not be much fear of its durability.

Iron-armoured lead-covered cables are not necessary if an effective system of conduits is used for mechanical protection. In Berlin, where such cables are employed, they are simply laid in a trench in the ground, and consequently require to be thoroughly protected from mechanical injury. Lead alone is not sufficient.

Dr. Werner von Siemens said in his recent paper that long years of experience had taught him that, although covered with hemp or jute, it requires further protection to render it secure against mechanical injury, whether by men or animals, as even rats eat their way through. Such protection is afforded by a double spiral of sheet iron, which again is made secure against oxidation by asphalting or galvanising, or by another cover of tarred hemp or jute. Such armouring as this is quite needless with a well-constructed conduit, but as to whether galvanic action takes place Dr. Siemens has undoubtedly shown by his firm's experience that with a substantial layer of tarred or asphalted jute between the metals it does not occur. This form of armoured cable was laid at Munich for lighting the theatre, and after nearly five years in the ground is as perfect as at first. At other central stations at Elberfeld, Darmstadt, Geneva, Salzburg, Lyons, the Hague, St. Petersburg, their iron-armoured lead-covered cables prove that constructed in this way there need be no fear of galvanic action at any rate.

Lead sheathing may be made durable, but the actual necessity of it where a conduit is used is quite another matter, and a consideration of the two principal divisions of insulating material has considerable bearing on this point.

Of the fibrous and the homogeneous the latter seems to present some important advantages for insulating high-tension cables. For instance, vulcanised rubber is flexible and tough, and affords a continuous and homogeneous covering which should be superior to a fibrous covering. Vulcanised rubber cables are at times sheathed with lead for mechanical protection, but such is not necessary if laid under good mechanical conditions, and Mr. Lant Carpenter recently said that the sulphur in the vulcanised rubber would attack the lead in the same way it would copper. If, as is stated by many English cable manufacturers, compound vulcanised rubber will well withstand the deteriorating effects of damp and gases, then, the mechanical protection being afforded by a conduit, the necessity of lead as a protector is no longer of importance. It is true unprotected vulcanised rubber cables in conduits have failed in the States, but the competition among electric light companies in America is notorious, and the question as to the maintenance of cables is not considered so much as their relative first cost. The object of the American cable manufacturers, naturally suiting their market, has been to make cables with a cheap form of vulcanised rubber insulation to compete with the jute-insulated cables there, and which are cheaper. The vulcanised rubber evidently was not properly prepared as it should be to permanently counteract the deteriorating effects of damp and gases by reason of the expense.

All those acquainted with the rudiments of rubber manufacture must be aware of the enormous difference in quality of different vulcanised rubbers. With Para rubber at 3s. per lb. and the desire to sell it at a shilling, all manner of substitutes and compounds have been introduced. While thoroughly appreciating the energy and genius of American electricians, we can confidently say that cables manufactured in this country are greatly superior to those made in the United States; and as a basis for this belief we have the fact that most of the cables for high-tension distribution in the States have proved faulty, according to their own admittance, while there is undoubted evidence of the successful working of many vulcanised rubber and jute-insulated cables in this country and in Europe, made by English manufacturers. The statement is made by the Silvertown Company, Messrs. Henley and Co., and others, that they are absolutely prepared to guarantee for a term of years their vulcanised rubber cables unprotected by lead, even if laid in damp and leaky conduits, provided there is suitable mechanical protection against injury and that the cables are laid under competent supervision.

With regard to *fibrous* insulating material it is alleged that it has the defect of opening cracks when bent. If this be the case it would become more pronounced when the material is soaked in resinous compound, and perhaps less so when petroleum residuums are used—such as, for instance, in ozite, kerite, bitite, etc. If cracks are likely to be formed when the cable is bent or twisted about, air paths would be opened up for disruptive discharges.

In the working directions given for the laying of one of the principal lead-covered cables in the States, it says "the fibrous material, being super-dried, will readily absorb and retain moisture from the air, and cables showing an insulation resistance of thousands of megohms when first made may, after exposure of a small part of the core to moist air for a few hours, show a great falling off of insulation resistance." Instructions are therefore given as to carefully sealing the ends of the cable when laying. Again, the splicers' hands are cautioned to be kept "perfectly dry and free from perspiration, as a little moisture communicated to the insulation may result in vastly lowering the insulation resistance." These remarks written by manufacturers of such cables show the readiness with which such fibrous insulation may deteriorate under conditions likely to occur even if there be the most careful supervision of the men laying the cables. It is acknowledged to be absolutely necessary to cover jute or cotton insulated cables with lead, and it is in this fact that the weakness of such cables seems to lie, as the moisture and gas resisting portion is the lead absolutely, the jute insulation being of little value in this respect.

Inasmuch as the majority of underground cables in the States are insulated with such jute or cotton soaked in some compound, it will be at once understood why lead-covered cables are considered in America as the only means for successfully carrying out such underground cable work, especially when the cables are liable to be laid in leaky conduits. It is right to say that apparently few troubles have been experienced in Europe with underground conductors insulated with fibrous material. Messrs. Siemens and Halske, who use a jute-covered cable, but manufactured in a different way both as regards the impregnating of the jute and the method of cold drawn lead sheathing, have a successful record, not only for low-tension cables, but for the various concentric cables supplied to Messrs. Ganz Company, of Buda-Pesth, for 2,000 volt alternating currents. They assert that the troubles experienced with American underground cables, whether jute or rubber insulated, are comparatively unknown.

The question between what I broadly term lead-sheathed jute or well-compounded vulcanised rubber seems to me the momentous one, and, as usual, each one has certain claims.

It is well known that the cost of jute-insulated cables is less than that of high-class vulcanised rubber insulation, but this would have little weight unless they can be proved in every respect equal to vulcanised rubber. In a comparison of the different costs of such insulation, vulcanised rubber appears to be about 25 per cent. more for approximately the same insulation resistance. In making this comparison I took the cost of a vulcanised rubber cable, insulated with one layer of so-called pure and two coatings of vulcanised rubber, taped, braided, and coated with preservative compound, but not covered with lead, as this is a superfluity, the cable being water-tight without this addition. The jute-insulated cable I took as cased with lead, and protected again by a covering of tarred jute yarn compounded.

After the relative cost comes the question of jointing, and as this is one of the most vulnerable points in any cable it is of vital importance that the joints should be made as good as any other part. With vulcanised rubber cables the joints must be vulcanised, and first-class rubber men, who would make such joints speedily, should be on the working staff. With lead-covered cables a plumber would have to be employed; and I am informed by those who have had experience with both forms of cables that the vulcanising is preferable to the plumbing.

Vulcanised rubber cables are certainly easier to handle, being more flexible, ductile, and lighter; and this is of importance in view of the difficulties occurring in drawing cables in and out of a conduit.

Again, when lead-covered cables are coiled round a drum, the part nearest the centre becomes compressed, while the outer portion is extended. On uncoiling the cable the opposite effect is produced, the parts before compressed being now pulled out, and the extended portion compressed. This is trying to an inelastic substance like lead, the more so when, unlike an empty lead pipe for water, it is filled with an insulated cable. It is quite conceivable that the surface of the lead may be slightly broken up, particularly when the method employed is to cover the lead hot round the cable, and although no cracks may be visible to the eye, gas and moisture might be apt to find their way in very quickly, with corresponding deterioration of the insulation.

Next, as to whether jute or vulcanised rubber is better suited for insulating high-tension alternating cables no opinion can yet be given. It is well known that on submarine cables working with reversed currents, it is usual at times to give the cable a rest. This necessity may be due to the action of the reversed current on the insulation, and it would be interesting to know how the much more powerful currents and rapid reversals of an electric light circuit will affect the insulation of a cable after carrying such currents for a considerable period. In some interesting papers, published last year by Mr. Addenbrooke, he came to the conclusion that a high-tension alternating current should have less effect on any dielectric than a continuous current of the same potential. He argued that, owing to the rapid alternations, there would not be sufficient time to fully charge the dielectric, as, before this could occur, the next charge would sweep out the former charge, partially recharging it in the opposite direction. But it would certainly appear that such an action as this on a dielectric would be far more injurious than for it to be fully charged as with a continuous current.

From a careful review of what I have seen in the States and elsewhere, I must confess that my own feeling is in favour of a cable insulated with thoroughly good vulcanised rubber for high-tension work, and I was interested to hear Sir William Thomson say on Monday, at the Board of Trade enquiry, that if high-tension conductors were protected in an iron pipe a lead sheathing to them was not essential.

Those acquainted with the present manufacture of rubber cables know that pure rubber proper is not used for their insulation. How-

Digitized by Google

ever good the rubber may be, there is always a certain amount of impurity and oils which will set up decomposition sooner or later. This is overcome by slightly vulcanising the rubber, but so that there shall be no surplus sulphur to attack the copper. In the high-class cables now made by the Silvertown Company and others, the practice is to put next the conductor, after cotton twist, a substantial coating of pure indiarubber, slightly vulcanised, upon this a coating of zinc rubber, with vulcanising materials, and, covering this, a compound vulcanised rubber of great resisting qualities to damp and gases. The zinc rubber takes up the surplus vulcanising material of its two outer coverings, so that the copper cable is not injured by the sulphur used in the process. Such an insulation as this is as good as could possibly be desired for any high-tension currents, and is absolutely perfect so long as the covering is continuous, and as the whole of the materials are treated at a temperature of 400deg. any rise in temperature of the conductor due to accidental overloading will not injure the insulation. With regard to the outer protection of the compound vulcanised indiarubber, there may be still scope for further improvement, and, for instance, in the cables recently made by the Silvertown Company for the London Electric Supply Corporation, two braidings of asphalted tape have been used, and this is found to be satisfactory. Among the instances where vulcanised rubber cables have stood stringent tests has been at Eastbourne, where Mr. Lowrie has used Silvertown cables, laid in iron pipes, for two years, and states they are still in perfect working order. He has also put down there a length of Fowler's Tatham lead-covered cable for continuous-current high-tension work, the fibrous insulation being well wrapped round several times with tape. This has also been working successfully, and in the House-to-House Company's station he proposes to try each method of insulation on different circuits, although the advantages of handling the indiarubber cables are in their favour.

The Silvertown Company have five miles of vulcanised indiarubber insulated cable sheathed with iron wires at Brussels, with 1,400 volts constant current. This was laid in the sewers two years ago, and is now quite satisfactory.

This company have also supplied two miles of such cable, but with asphalted tape on the outside, to the London Electric Supply Corporation, with 2,400 volts alternating current, the conductors being laid in an iron pipe.

There are also samples on the table of a piece of Messrs. Henley's vulcanised rubber cable that has been in use overhead for 10 years.

A difficulty with underground conductors in the States seems to be disruptive dicharges, and I trust the discussion may bring forth information on the subject. Owing to the frequent puncturing of the insulation, attended with pinholes in the lead covering, Mr. Ascherson, the Waring Company's able electrician, and whom I desire heartily to thank, turned his attention to the matter, as the pinholes by admitting moisture defeated the object of the lead sheathing, and proved fatal to the life of the cable.

Mr. Ascherson's theory is that the static electricity generated in the cable after a time punctures the dielectric by discharging itself between the copper conductor and the lead sheathing ; and the protector shown in Fig. 13 is designed to obviate this.

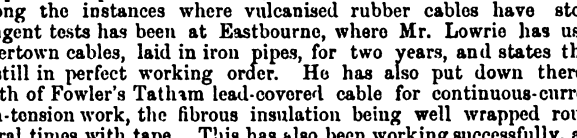


FIG. 13.

This consists of two metallic points, separated by a distance which is less than the thickness of the cable insulation. The one point is connected to the lead sheathing, and the other through a fuse wire to the copper conductor, the idea being that the static discharge would take the shorter path between the points instead of rupturing the insulation. Mr. Ascherson says these dischargers should be placed at every section of a cable, and if the sections are more than 200ft. long there should be one at each end.

To show the exceedingly minute path necessary for a discharge, it may not be out of place to quote Mr. Ascherson's experiment. A plate of glass about one-tenth of an inch thick was broken in two pieces, and the two parts immediately fitted to their former position and clamped ; the restored plate was placed between two discharging points, and so long as the points were over the solid glass no discharge was obtained, but upon removing it, so that the line joining the points would lie in the plane of the fracture, a discharge immediately occurred.

A possible cause of a disruptive discharge might be that on high-tension circuits of great self-induction, as, for instance, on arc-lighting circuits, where lamp coils form part of the line, the induced current on breaking the circuit is very violent, and in preference to discharging through the line, and consequently the lamp coils, it gets away by rupturing the weak insulation and passing through to the outer earthed casing.

The exemption from such trouble is credited by many entirely to a thicker insulation being used, and in calculating the insulation for a high-tension cable it should be made sufficient to withstand a disruptive discharge of this nature and tested accordingly. For instance, owing to the almost daily occurrence of burn-outs with some cables in Chicago with $\frac{3}{32}$ insulation laid in November, 1887, the four miles laid in December, 1887, had $\frac{4}{32}$ insulation, and the two miles laid early in March, 1888, have $\frac{6}{32}$ insulation. Careful experimental work is essential before the sufficiency of insulation for such underground cables can be accurately determined, and our leading cable manufacturers naturally keep the results of such experiments to themselves.

Concentric cables, although so extensively used by Messrs. Ganz, of Buda-Pesth, in their stations, do not appear as yet to have met with favour in the States. It is, of course, undesirable to use ordinary lead-covered cables for alternating currents, both on account of the loss from induced currents in the lead sheathing and the annoyance to workmen handling them. If, for instance, while handling a conductor conveying such a current the lead covering be insulated to any extent on each side of them, the workmen would receive the induced currents through their bodies. Again, when the two lags of an alternating current are in separate cables, and the cables laid in insulating materials, any chance contact or connection between the leads might cause the induced currents to pass backwards and forwards at these points, thus tending to cut away the lead covering as the result of any sparking at poor contacts between the two leads. The Waring anti-induction cable, with both wires enclosed in one sheathing, is well known, and in this the currents induced by both wires, being equal in power and opposite in direction, tend to neutralise one another.

Mr. Ferranti, by employing concentric cables for conveying the high-tension currents from Deptford station, has brought such cables into prominent notice in England. A concentric cable is obviously the best on theoretical grounds for the elimination of induced currents, as their reaction upon one another is necessarily strongest in the axis of the current. The question as to the necessity of insulating the outer conductor of the concentric cable has recently had considerable attention give to it by Mr. Preece on behalf of the Post Office authorities, and as a result of his experiments they evidently must be so insulated. All the concentric cables made by Messrs. Siemens and Halske for Messrs. Ganz and Co. are of the usual stranded wire form, and the outside conductor, after being well insulated with jute, is covered with a cold-drawn lead tube, having an outer iron armouring as previously described. These cables have been successfully used in Rome, Tivoli, Turin, and Milan, in each case carrying a potential of 2,000 volts.

The difficulty of making satisfactory joints with concentric cables must be to a certain extent against them, as it is impossible to see what has been done inside. Messrs. Siemens say that it can be readily accomplished, and the illustration shows the manner in which the joints are made in their cables. The Silvertown Company have made several forms of concentric cables, highly insulated with vulcanised rubber, with considerable success for ship work, and they also have an arrangement for constructing the joints.

As to whether concentric cables will be largely used in this country much depends upon the system of distribution employed. For long lengths of cable used as feeders to sub-centres, or to systems of distributing mains, they would be of considerable advantage, as no joints would be required *en route*, but in house-to-house distribution, with frequents joints, a pair of separate cables near to each other would appear the more easy to handle and the more practicable to operate. In summing up this matter it would appear that the relative advantages are as follows : 1st. The greater convenience of making joints on separate leads as against the trouble involved with concentric cables. 2nd. As regards the relative cost between two separate cables and concentric cables with the same insulation resistance, vulcanised rubber unsheathed concentric cables with outside insulation are dearer, but with jute insulation for concentric cables and lead sheathing they are cheaper. 3rd. There remains the increased efficiency on an extensive system of alternating currents by the use of the concentric form.

With regard to the second point, the figures showing these are : For vulcanised rubber, two Silvertown $\frac{7}{16}$ conductors insulated to 5,000 megohms at 60deg. F., taped and braided over all, specially prepared for underground work, £255 per mile each = £510.

A concentric conductor of equivalent capacity, the internal conductor insulated to 5,000 megohms, as above, but the outer to 3,000, only = £900, being a difference against the concentric conductor of £390 per mile. If the outer insulation is reduced to 1,500 megohms, the price falls to £630 per mile, which is £120 above the cost of separate leads.

On the other hand, for Messrs. Siemens' specially prepared jute insulation two single conductors of same insulation at £220 per mile each, £440.

A concentric conductor of equivalent capacity, the outside insulated to 900 megohms, lead sheathed, taped and asphalted, £363 per mile.

All cables for high-tension currents should be well tested before leaving the factory. In other branches of engineering the engineer would not think of receiving his steam or hydraulic pipes without first seeing them tested to, say, over twice their working pressure. It is not sufficient for him to see simply that they will hold water or steam, but he must satisfy himself that they are strong enough for the pressure they have to carry. In the same way the electrical conductors which have to transmit energy, much as the steam and hydraulic pipes do, should be tested to twice their working pressure. With the outside well-earthed current should be allowed to traverse the conductor a considerable time, and an electrical test taken afterwards for insulation. With electrical cables for underground work passed in this way, and satisfactory in other respects, there should be no fear of breakdowns under ordinary conditions.

In dealing with a subject of such wide extent and great importance as this, it is impossible to do justice to all the workers in the field. I have left out much that may be considered interesting and important, but the difficulty has been, with the mass of imformation on the subject, what to put in and what to leave out. Doubtless there are many instances of cables and conduits having been successfully at work which have not been mentioned in this paper, and I hope such information will be forthcoming. If the discussion following be the means of clearing up some of the doubtful points surrounding the subject of underground electrical work, and of demonstrating the direction in which successful work should be undertaken, the object of this paper will be fully accomplished.

Digitized by Google

had told them, on the banks of the canal. For that work £30,000 would be ample. Their intention was to make similar arrangements for the districts of St. Martin's and the Strand. The capital expenditure proposed by Prof. Forbes would be equal to £2. 4s. per 30-watt lamp fixed, or £3. 6s. running. Those figures, compared with £1. 12s. per lamp fixed, and £2. 8s. per lamp running, of the E.P.S. system. Two pounds eight shillings per lamp running was the most economical limit at which the E.P.S. system could be carried out, and he had allowed a margin, leaving it at £3 per lamp in his estimate of £30,000.

Mr. Russell Griffiths then opened his case on behalf of the Commissioners of Sewers for the City of London. He said that on their behalf he had to object to the application of both the London Electric Supply Corporation and of the Metropolitan Company for provisional orders for the City of London. There were three main grounds on which he objected to the orders. One was that the Commissioners of Sewers, who had been in existence since 1848, and who had hitherto had the lighting of the City, were quite capable of conducting their own affairs. The Sewers Act, which was an Act of 1848, constituting those Commissioners, gave them, by the 116th section, express authority to enter into such contracts with such gas companies and other persons as they might think fit, to supply gas, or to light the City by any other mode, and also it gave them express authority to inflict such fines or penalties as they might think fit where such contracts as they entered into were not faithfully carried out. Those powers were subject, as all powers must be, to Acts of Parliament, which might give rights to other companies to come in and deal with such matters. He was not going to contend that the Commissioners of Sewers would not be bound by such Acts as Parliament thought fit in its wisdom to make. What he did claim was that they had sufficient facilities given to them to contract for public and private lighting, and that they were persons who, as he would show, by their acts hitherto, and the way in which they had dealt with gas and electricity up to this time, ought to be entrusted with the lighting of the City of London. What he proposed at present, therefore, was to ask the inspector to consider the powers of the Commissioners from a local point of view, and what these two orders sought to impose upon the City—the obligations which they sought to impose and the corresponding benefits which they put forward as coming to the City if they were allowed to have those Parliamentary powers. He did not propose in any way or as little as he could to contrast the relative advantages of the two proposed systems of supplying electrical energy which had been detailed by so many scientific witnesses. He was quite content to take what his learned friend Mr. Moulton had said about the difficulties that the alternating system would have to contend with, in fact, the scientific difficulties that the two companies would have to overcome before they could be safely entrusted to go into a very compactly inhabited district. As to the second ground of objection, he thought he had better take it separately as regarded the two companies, because although they both intended to use the transformer system, they intended to use it under very different conditions, and he would deal with each of the companies not very exhaustively, but sufficiently for his purpose, to show that there were difficulties in each of their systems, and that in neither case ought the Board of Trade to impose on the City the rights claimed by those companies, and the corresponding inconveniences which the inhabitants would have to put up with. There had been some doubts expressed by several of the witnesses as to the feasibility of having such a generating plant as that proposed for Deptford. They had the extraordinary evidence that the engines of 10,000 h.p. would be equal to what supplied 120 installations in America, so that if the Americans had hitherto been credited with being a go-ahead people they would have to hide their diminished heads in the matter of electricity. He submitted that that was an entirely unsafe power to use in generating electricity. The generating station was situated at some distance from London, and all the plant being under one roof formed practically one generating unit for the supply of electricity, and he submitted that that was a source of great danger. There was no possibility of storage, and it would be very unsafe for the City to depend for its supply of light under such circumstances. The trunk mains were to be carried outside the railways, and would be in exposed conditions, and would be liable to damage either by accident or design, which would practically extinguish the whole supply from that particular company. He submitted that these were very cogent reasons why the City should not have its supply from that company. He wished to ask whether such a system could be confidently recommended as more than an experiment. They had it from Lord Crawford that they would run a main on each side of the street, which would be connected with one another in case of accident. The mains were to be rigid in form, and up to this time there had been no experience with such mains in this country. The whole of the present system of lighting from the Grosvenor Gallery had been by overhead wires, the insulation of which was much more perfect than that of underground wires. The tendency of the joints would be to get out of order considering the high tension—namely, 10,000 volts—at which it was intended to bring the electric current from Deptford to London. There had been evidence to the effect that transformers did not always do their work. It might be that the transformers of the London Electric Supply Corporation were better than those about which they had had evidence from America, while it had been stated that it was possible for a high tension to pass through a primary into a secondary converter. At the same time they had had evidence as to an accident that had happened to a gentleman at Pittsburg, America, with a voltage of 1,000, and it was quite clear that there would be considerable danger, if anything happened to the transformer, to the inhabitants of a house where such a system was adopted. If they were going to introduce an element of possible danger into the City, the Board of Trade must see that sufficient precautions were taken for the safety of the public in order to avoid any such contingency. The witnesses had pointed out the difficulty of connection there was between these rigid mains and the supply mains for a house. There was another matter in connection with the alternating system which he would like to emphasise, and that was that no motor for electrical energy had been yet discovered for it. The demand for motors had been constantly increasing in Berlin and New York, and possibly that might be the case in London, and one witness pointed out that the poorer class of people would be more likely to require electrical power rather than the light, and in neither of the provisional orders with which he was dealing was the supply of elect icity for any other purpose than lighting contemplated. In fact, in the agreement made by the Metropolitan Company with the Strand district there was an actual prohibition against the owner or occupier of any premises using the electricity supplied to him by the undertakers for any purpose other than lighting. Both orders were confined to electric lighting, and a great number of persons would prefer, if they were going to have a constant disturbance of the streets and a taking in and out of those cables, to have such a system as would supply motive power as well as light. Having dealt with the question of the want of storage in the system and the difficulty, as alleged by several of the witnesses, of properly insulating the mains, he said that competition in the City would be very inconvenient, he might almost say impossible. The streets were absolutely full, and it was impossible that more than one company could go into any particular district. He submitted that the local authority was the proper body to deal with the whole question. It was impossible to suppose that under the orders which he now opposed, and as they were now drawn, the City would be most unsatisfactorily lighted, and there were special circumstances connected with that portion of the metropolis which entitled the authorities to have some control over undertakers or companies of that description. He could quite understand that, as in the case of a railway or any other great public improvement, where there was an obstructive local authority who would not allow an undertaking to be carried through their dominions, it might be quite necessary that they should be disregarded and their wishes overlooked, but where they had to deal with a matter of this kind, when there was sufficient area in which both companies could exercise their ingenuity and enterprise, and increase their capital by multiplying their stations, he submitted that there was no occasion for interfering with the existing condition of things. In the present state of electric lighting, it was quite sufficient that those companies should have an area that would occupy them on a small scale. There would be no hardship either on the citizens of London or on the respective undertakings if they did not get their provisional orders, because the City of London would be quite safe in the hands of the Commissioners, who were trying to do the best they could for the future electric lighting of the City, because the provisional orders applied for, however beneficial for the companies concerned, were not conceived in the interests of the public at large. On these grounds he would ask the inspector to say in his report to the Board of Trade that there were special reasons for not including in those provisional orders the area of the City of London, and, secondly, that the form of electricity most adapted to it would be that the energy of which might be equally useful for electric lighting and motive power. He could assure the inspector that the Commissioners were not desirous in any way of putting a stop to the extension of electric lighting. On the contrary, they really wished to foster it; but they did not want to have such conditions imposed upon them as were contained in the provisional orders now applied for.

COMPANIES' MEETINGS.

INDO-EUROPEAN TELEGRAPH COMPANY, LIMITED.

The twenty-second ordinary general meeting of this Company was held on April 29 at Winchester House, Old Broad-street, Mr. J. H. Tritton presiding.

The **Chairman**, in moving the adoption of the report and the payment of a dividend for the half-year ended December 31 last of 17s. 6d. a share and a bonus of £1 a share (making with the interim dividend a distribution of 10 per cent. for the year), stated that the receipts for the year had been £110,327, or an increase of £6,036 over those of 1887, while the expenses had been £52,393, or £3,772 in excess of those of the previous year, the chief increase being £955 in agency expenses. From some points of view the traffic had been slightly discouraging, although there had been an increase on the whole. The Indian traffic had not brought them the results which they might have reasonably expected. So far from benefiting them, they had suffered from the reduction of the rate in 1886, the increase in the receipts which he had mentioned having been made up by Trans-Indian, Australasian, Persian, and South Russian messages. In 1880, the number of words per message was 18·83; it had gradually declined until in 1888 the number of words per message was only 12·66. This decline must, they supposed, be attributed to the greater perfection in what was called "coding," by which very much more was conveyed than the number of words employed. A review of all the circumstances led them to the conclusion that it was not so much the tariff which regulated the traffic as the activity or sluggishness of trade and commerce. Next year there would be a telegraphic conference in Paris, and they looked forward to it with feelings not altogether unmixed with anxiety. They never quite knew what might be said or done at these conferences, and the reductions in the tariff which had been made at them in the past had not proved very fruitful, for the European telegraphs, which were mostly in the hands of Governments, were worked at a loss. He believed he was right in saying that our own British telegraph service was worked at a loss, and the question arose how far the senders of messages, who forwarded them because they

Digitized by Google

expected to make a profit out of the business they were conducting, were to be practically subsidised at the cost of the general community. The telegraph ought to pay for itself, and return a fair interest upon the capital and labour employed, just the same as any other business, whether its proprietors were States or private individuals. He concluded by referring with regret to the death of Colonel Holland, who was chairman of the Company for 20 years.

Mr. H. Weaver seconded the motion.

In answer to Mr. Jackson, the **Chairman** stated that at the time when they paid no dividends they could not start a sinking fund, as provided in their old articles of association. Latterly their circumstances had enabled them to put by money, until now they had more than 25 per cent. of their capital in reserve. They must look upon that partly as a fund against contingencies and partly in the light of a sinking fund. Their concessions would come to an end in rather less than 20 years. There was a clause both in the Russian and the Persian concessions under which the Company was bound to come to terms with those Governments, and they hoped and believed that that implied that the Governments would conceive themselves reasonably bound, in considering the terms, not to enter upon a course of confiscation. Mr. Jackson's remarks implied a desire that they should divide their reserve fund, but he thought it was always advisable to have a substantial amount in reserve against any contingency.

The motion was then unanimously adopted, and the retiring Directors and Auditors were subsequently re-elected.

NEW COMPANIES REGISTERED.

Brompton Electric Fittings Company, Limited.—Registered by Deacon, Gibson, and Medcalf, 4, St. Mary-axe, E.C., with a capital of £2,000 in £1 shares. Object: to supply public or private buildings with gas and electric light, and the fittings for the same. Registered without articles of association, and consequently the regulations of table A in the first schedule of the Companies' Act, 1862, apply.

CITY NOTES.

Great Northern Telegraph Company.—Messrs. C. J. Hambro and Son will pay the excess dividend on the Great Northern Telegraph Company's shares at the rate of 5s. per share on presentation of coupon No. 15 for the year 1888.

London Address.—Mr. Samuel Elliott, of Albert Moulding Mills, Newbury, the well-known manufacturer of wood casings for electro wires and cables, has taken London offices and showrooms at 63, Finsbury-pavement, E.C., opposite Moorgate Station. The firm's head office will still be at Newbury.

West India and Panama Telegraph Company.—The report for the half-year ended December 31 shows a balance of £22,892, out of which they have placed £1,000 to reserve, and propose the payment of 12s. per share on account of arrears of dividend on the first preference shares, the balance to be carried forward being £1,154.

Consolidated Telephone Construction and Maintenance Company.—The Directors of this Company recommend a final dividend at the rate of 7 per cent., less income tax, making, with the interim dividend, a distribution of 6 per cent. for the year ending March 31, after writing off £2,500 and carrying forward about £1,700.

West Coast of America Telegraph Company, Limited.—The report of this Company shows a gross income of £65,714 for the year ending December 31, against £57,893. After deducting debenture interest and all other charges, and providing for the dividends paid in July and January, the Directors recommend a further distribution of 2s. per share, payable on the 16th inst., making 6 per cent. for the year, to write off £500 from the value of the repairing steamer "Retriever" (thereby reducing her valuation in the books to £17,000), and to add £12,000 to the reserve fund, making the latter £39,000, leaving £480 to be carried forward.

Brazilian Submarine Telegraph Company.—The report of the Directors of this Company for the half-year ended December 31, 1888, to be submitted to the thirty-first ordinary general meeting states that the revenue for this period amounted to £133,708, and the working expenses to £23,553. After providing £12,880 for debenture interest and sinking funds and £1,985 for income tax, there remains a balance of £95,289; to this is added £4,539 brought forward from June 30 last, making a total of £99,828. First and second interim dividends amounting to £39,000 have been paid, and £40,000 transferred to the reserve fund, leaving the sum of £20,828 to be carried to the next account. Of this amount the Directors intend distributing £13,000 to the shareholders with, and in addition to, the quarterly dividend payable in June. In accordance with the provisions for repayment of the first issue of debentures, dated July 31, 1884, 145 bonds, representing £14,500, were drawn on the 12th ult. for payment at par on July 31 next. This, with the previous drawings, will make a total repayment of £65,500, leaving £84,500 of the first issue of debentures outstanding. The question of a reduced rate to Brazil has been under the consideration of the Board for some time, and it has been decided that reductions should be made in the tariff to Madeira, St. Vincent, and Pernambuco. It is anticipated the alteration will at the commencement affect the Company's revenue, but that the growth of traffic resulting from the reduced rates will greatly diminish the possible loss. Under an arrangement with the African Direct, the West African, and the Eastern and South African Telegraph Companies, additional traffic will be brought to this Company's lines between St. Vincent and Europe by the new cable now being laid to the Cape of Good Hope.

PROVISIONAL PATENTS, 1889.

APRIL 23.

6804. **Improvements in telephone transmitters.** William Robert Lake, 45, Southampton-buildings, London. (James Straton, Canada.) (Complete specification.)

APRIL 24.

6847. **Improvements in meters for registering the passage of electric currents.** George Edensor Dorman, The Hawthorns, Stafford, Staffordshire.

6865. **Improvements in secondary batteries.** George Eduard Heyl, 23, Southampton-buildings, London. (Complete specification.)

6867. **Improvements in "holders" for incandescent electric lamps.** Charles Richardson and George Hill, 74, Barrett-street, Brooks Bar, Manchester.

6869. **An improvement in the casings or covers of electric switches, cut-outs, and wall and ceiling fittings.** Joseph Slater Lewis, 53, Chancery-lane, London.

6875. **An improved construction and mounting of the spring armature and hammer for electric bells and other like electrical instruments.** James Charles Williamson, 34, Southampton-buildings, Chancery-lane, London.

APRIL 25.

6883. **Improvements in self-exciting alternate current dynamos, and self-starting synchronising motors.** Llewelyn B. Atkinson, 23, Andalus-road, Clapham.

6884. **Improvements in the means of obtaining motive power from alternating currents of electricity.** Llewelyn B. Atkinson, 23, Andalus-road, Clapham.

6885. **Improvements in apparatus for use with variable currents, and in the means of obtaining motive power from alternating currents of electricity.** Llewelyn B. Atkinson, 23, Andalus-road, Clapham.

6942. **Improvements in electrical accumulators or storage batteries.** Johannes Zacharias and Friedrich Marx, 4, South-street, Finsbury, London.

APRIL 26.

6954. **Improvements in meters for registering the passage of electric currents.** George Edensor Dorman, The Hawthorns, Stafford, Staffordshire.

6974. **Improvements in regulators for controlling the production and utilisation of electric currents.** George Edensor Dorman, The Hawthorns, Stafford, Staffordshire.

6981. **Improvements in annunciators in connection with electric, pneumatic, or other bells.** Jesse Kemsley, 57, New Broad-street.

7002. **Improvements in electric secondary or storage batteries.** Thomas Hammill Hicks, 45, Southampton-buildings, London. (Complete specification.)

7005. **Improvements in galvanic batteries.** Alexander Schanschieff, 24, Southampton-buildings, London.

APRIL 27.

7023. **Improvements in electric meters.** Robert Snowdon, 70, Market-street, Manchester.

7037. **Improvements in electricity meters.** James Blyth, 87, St. Vincent-street, Glasgow.

7038. **Improvements in electric-battery cells for lightening or for other purposes.** William Balch, 7, Field-view, London-fields.

SPECIFICATIONS PUBLISHED.

1888.

5098. **Electrical signalling for telephonic circuits.** Krieboom. 8d.

5162. **Electric generators.** Mordey. 8d.

5531. **Electric lighting, &c.** Statter. 8d.

7655. **Electric conductors, &c.** Crompton. 1s. 1d.

8099. **Electrical hoists.** Crompton and others. 8d.

NOTES.

Madagascar.—The telegraphic lines in the Island of Madagascar has been destroyed by floods.

Electric Cabs.—Cabs driven by electric motors are mentioned as running at Washington and at Foree Bain in the States.

Paris Congress.—The congress at Paris during the Exhibition on the subject of electrical science will be held from August 24 to 31.

New Cable to Cape Town.—The new cable of the Eastern Telegraph Company to Cape Town along the West Coast is now completed.

Nantua.—M. Bertolux, who has fitted up central stations at Perigueux and St. Vierzon, France, has commenced the construction of a similar undertaking at Nantua.

Cost of Traction.—The Julien Company, of New York, speaking from experience, gives the cost of motive-power as 13s. for a car-day of 60 miles. This is 2·6d. per car-mile.

Brush Shares.—The debentures of the Anglo-American Brush Electric Light Corporation were over applied for, and the letters of allotment and of regret have been posted.

New Journal.—We have received the first number of the *Rapid Transit News*, a new journal published in Chicago for dealing exclusively with the ever-increasing tide of electric traction.

Mix and Genest.—The incorporation of this firm as a company in Berlin is now accomplished, with a capital of over 1,000,000 marks. A large extension of the factory is contemplated.

Students' Meetings.—A discussion on Prof. Forbes' paper on Central Stations took place last Friday. The next students' meeting will take place at the Sanctuary, S.W., on Friday, May 17.

Electric Traction in Paris.—It is announced at Paris that MM. Philippart Frères are about to renew their experiments of electric traction by accumulators upon one of the northern tramway lines.

Electric Light Casings.—The Gloucester Railway and Waggon Company, Gloucester, sends us a price list of casings for electric light wires, in which many neat and cheap mouldings are illustrated.

Metropolitan Railway.—We do not hear much about the experiments upon the underground railway. Probably both railway and traction people are waiting to see the result of the Southwark Subway Electric Railway.

Death of Col. McMurdo.—Col. McMurdo, of Berkeley-square, originally of Kentucky, died on Tuesday. He was concerned in Italian tramways, and was said to have recently acquired a new system of application of electricity to street cars.

Electric Verdant Indicator.—An electric invention is announced which rings a bell in the hotel office, and indicates the room number to call attention when any particularly verdant person blows the gas out instead of turning it off. Invented for Americans.

Cubzac.—The installation put down for lighting the town of Cubzac comprises two compound-wound Gramme machines of 135 volts and 90 amperes, serving 300 lamps of 10 to 16 c.p. Accumulators are kept in reserve. The concession, extending over 20 years, has been granted to M. Cun.

Melbourne.—Machinery for a complete electric tram-car system has recently been sent out by Messrs. Elwell-Parker for Melbourne. We also understand that they have in hand a set of plant for the same place for electric lighting, consisting of a central installation system for 6,000 16-c.p. lamps.

Buckingham Palace. — The electric lighting of Buckingham Palace has been extended, and the entrance hall, the marble hall, the grand staircase, the ballroom, the picture gallery, the promenade gallery, the dining-room, the blue drawing-room, and the saloon are all now lighted by it.

Spain.—On the 23rd of April the electric light was inaugurated in the town of Durango. At Albacete there are 864 lamps, and orders for 300 more have been received, but the Spaniards do not take up the light as quickly as expected, as the works were constructed on a scale contemplating a much greater demand.

Municipal Lighting in France.—Another instance of the municipal substitution of electric lighting for gas is that of the town of Lonhaus, where the town authorities have unanimously decided to substitute electricity for gas, from the 1st May, 1890, and have authorised the necessary arrangements to be made subject to their approval.

E.P.S. Company.—Mr. J. Irving Courtenay, managing director of the E.P.S. Company, writing to the *Times* to correct a serious misstatement attributed to the counsel for the London Electric Supply Corporation, mentions that the number of the shareholders is 511, and the authorised capital is £200,000, of which £149,450 is issued and fully paid up.

Novelties Exhibition.—An exhibition of novelties is to be opened on May 29, at the Central Hall, Holborn, to remain open till the end of July. The exhibits are to include all kinds of useful or scientific novelties. The hall, which is of 26,000ft. floor space, is a reconstruction of the old Holborn Theatre. The secretary of the exhibition is Mr. J. T. Alston, 15, Queen-street, E.C.

Gas-Heating Cylinders.—Messrs. Bryan, Donkin and Co. adopt the opposite method to water jacketting used in gas-engines, by gas jacketting steam-cylinders. By this means the cylinder is heated by gas, and the water which condenses on entrance is again evaporated and so increases the expansion. Messrs. Donkin have a model with glass cylinders on which the effect can be watched.

Electric Trams in Liverpool.—The City Council of Liverpool passed a resolution on May 1 that, subject to the sanction of the Board of Trade, the tramway companies would have their consent to run accumulator cars on the Liverpool lines. The Liverpool Tramway Company have sent down the wheels of one of their cars to be fitted with electric gearing by the Electric Traction Company.

Tramcars for Edinburgh.—It is thought that the tramcars of Edinburgh will be run by electricity before long. The hills are very steep here, and the probability

Digitized by Google

is that two motors, one to each axle, would be used, the second motor only being used for the steep hills. This will make the getting up a hill a little more expensive, but the fair city will be better served with electricity than at present.

Belts.—To prevent the slipping of belts, a point to be guarded against when lighting direct by dynamos, a German journal advises washing the belts from time to time in warm water to remove clogs of dirt, and to brush them, afterwards lubricating them with equal parts of tallow and train oil. It is sufficient to lubricate them from the outside if desired. Lubrication keeps the belts supple ; mineral oil of any kind should not be used.

A New Excitant.—We learn that a new method has just been invented for chemically extracting mercury out of cinnabar, the ore of mercury. The bye products, which still contain a considerable amount of mercury, can be used as an excitant in a primary battery after the manner of the Schanschieff battery. The inventors are Messrs. Webber, Niblett, and Carver, who have jointly patented the process.

Paris Exhibition.—The Exposition Universelle was publicly opened last Monday and some 250,000 persons were admitted. The grounds and buildings are finished, but it will be probably some few weeks yet before every exhibit is complete. The Eiffel tower is finished and will be opened to ascent on May 15. The immense electric light on its summit, at an altitude of 1,100ft., is said to render print readable at a distance of seven miles.

Voltmeter Competition at Berlin.—The Berlin Electrical Society have instituted a competition for the construction of a voltmeter which shall be independent of variation of temperature or other disturbances; or, failing such an instrument, of an apparatus which shall control the working of the voltmeter, and indicate exactly the time during which the difference of potential has had a lower or higher value to its normal value. The premium is 1,000 marks, or £50.

Architects' Association.—This association has an annual festival, which this year took the form of the performance of a play at the Westminster Town Hall. There was some difficulty about the supply of light for footlights, and the aid of electricity was called in. Twelve accumulators with incandescent lamps were fitted up, with a resistance to turn the lights up and down, and the lighting proved very satisfactory. The work was carried out by the Acme Electric Works.

Admiralty "Voice Tubes."—There seems to be considerable activity in the Admiralty Department in electric bells and indicators, or, as they are known in official parlance, "voice tubes." The Acme Works have supplied some 400 of these instruments, and other firms we have heard of are making or tendering for the same kind of apparatus. The voice tubes consist of an electric bell with three indicators to Admiralty pattern, for use in signalling orders to the engineers.

Magnetic Ore Separator.—Edison is now reported to be at work on a magnetic ore separator for use with crushed ores, diverted, after crushing into different shoots, by strong magnets. A similar apparatus was shown in the Inventions Exhibition for sorting rubbish from nails, etc., but we are not aware whether the invention has been applied to much practical use in England. A company is being formed to work Edison's separator, and machinery is being put up at a cost of 35,000dols.

Telegraphs as Investments.—The *Financial News*, specially commenting on the good prospects of the Great Northern Telegraph Company of Copenhagen, says: "Telegraphs are still an out-of-the-way market, frequented only by investors with special information. The average broker does not take much trouble to bring it under the notice of his clients, and the opportunities it affords for getting a good return with fair security are not so freely taken advantage of as they might be."

Series v. Accumulators.—An amusing instance of the interchangeability of electric tramcar systems occurred in a discussion the other day. A certain noble lord interested in series was talking to another noble lord who swears by storage cars. What would you do, suggested the latter, in the case of a single car or two wanting to be run for workmen at 5.30 in the morning, and not another required till seven o'clock: would you keep your series apparatus running for these? Oh, no, said the series man; that difficulty would be easily got over: I should use storage cars!

New Paris Theatre.—An international theatre will be erected at the foot of the Eiffel Tower for the purpose of performances being given therein by the people of all nations. The theatre, which has been contracted to be opened on the 10th June, will hold 2,000 persons, and will have attached to it a smaller theatre for about 300 for experimental purposes. The whole building will be lit by the electric light. Mr. Seymour Wade, the Theatre, and of Blomfield House, London-wall, E.C., has the arrangements in hand.

Electric Date Stamps.—The various telegraph companies are appreciating the virtues of the electric date and time stamp, and are, we hear, ordering in considerable quantities. The Post Office are open to adopt them, if the usual progressive number can be stamped at the same time. Mr. Randall is at work adapting his instrument to this purpose. They are also being used for checking-in workmen, and several other purposes. The Helsby Manufacturing Company have made one lot of them, and we understand that the Acme Electric Works have recently contracted for a number.

American Engineers in London.—At the last meeting of the Court of Common Council, the Lord Mayor laid before the Court a letter from Sir G. B. Bruce, the president of the Institution of Civil Engineers, applying for the use of the Guidhall for the purposes of an international banquet on Thursday, 13th June, to be given by the institution on the occasion of the arrival in this country of the representatives of the leading American societies of civil, mining, mechânical, and electrical engineers *en route* to the Paris Exhibition. The request was unanimously complied with, and the City Lands Committee were directed to make the necessary arrangements.

Electric Light in Printing Offices.—We are glad to see that the smaller printing offices are taking up the electric light. We heard some little while ago that the *West Middlesex Standard*, printed at the Broadway, Ealing, was lighted by electric light, and being in the district this week we looked in and found one of the neatest printing and composing rooms to be desired. The printing presses are run with a 4 h.p. Otto gas-engine, indicating up to 7 h.p., and this also drives a dynamo, Maxim-Weston type,

Digitized by Google

for lighting the premises. There are 47 16-c.p. lamps, and eight 50-c.p. lamps, which are run at the same time as the machinery, with very satisfactory results.

Health Congress.—The Health Congress opened last week at Hastings with a sitting of the municipal sanitation section. Major-General Webber, C.B., president of that section, delivered an important address on "Lighting of Towns in Relation to Health," warmly advocating the superiority of the electric light, which system of lighting, he argued, must become general, and be produced nearly as cheaply as gas in the near future. He specially commended the light on sanitary grounds. Prof. Ayrton advocated gas for heating, and the electric current for lighting and ventilation, observing that if gas were generally used for heatng it would do away with the dark clouds now hanging over great cities.

Australian Enterprise.—Miss Cornwell, known as "Princess Midas," the rich Australian lady who was to have bought the Schanschieff battery patents, is now in London, and has taken offices at 32, Queen Victoria-street, City, bent on projects to "advance Australia." We don't know how far electric lighting, traction, and mining come within her province, but as she has more than once evinced interest in things electrical, those interested in such plant suitable for Australia might be glad to be able to communicate with Miss Cornwell while in England, as it is well known she has various schemes on hand for the general benefit of her native land, and the pockets of various shareholders.

Immisch Dynamos.—Some very neat and well-engineered dynamos for lighting purposes are being turned out at Messrs. Immisch's works, under the superintendence of Mr. Albion T. Snell. We lately saw some of these; one for 12,000 watts, standing only 20in. high, looks a thoroughly good piece of work, from a mechanical point of view, and very compact for the output. A large machine for 50,000 at 400 revolutions, or giving up to 100,000, if necessary, was in progress on the lathe. We understand that the works are very busy, more orders being in hand at present than before at any corresponding period, a large amount being for motors for mining purposes, both for English mines, and for the Colonies, and abroad.

Electricity in Literature.—We learn that in the June number of *Scribner's Magazine* there will be begun a series of popular articles on the Practical Applications of Electricity. Among the subjects to be treated, the following are now arranged for: "The Principles of Electricity," by Prof. Cyrus F. Brackett; "Electricity in Modern Telegraphy," by Charles L. Buckingham; "Electricity in the Household," by A. E. Kennelly; "Electricity, and its Relations to the Human Body," by Dr. M. Allen Starr; "Electricity in Warfare," by Lieutenant W. S. Hughes, U.S.N., and Lieutenant John Millis, U.S.A.; and "Electricity in Large Industries," by a gentleman whose name is yet to be announced. The series will be elaborately illustrated by the best American artists and engravers.

Copper Refining.—Depositing dynamos have recently been supplied by Elwell-Parker to the extent of 1,000 h.p. for copper refining at Widnes. The process is far cheaper than the ordinary method, costing only about 10s. per ton. The method employed generally consists in first buying oxides as rich in silver and gold as possible; casting these in thick plates of 1in. to 2in. thick, roughly cast in a tray successively one on top of the other, with a little powder between, and then split up into plates. These are used as anodes in a depositing bath of sulphate of copper, the pure copper depositing, and the impurities, together with the precious metals, settling as a kind of sludge. The plates are usually some three feet by two, and at the works in question 56 tons of pure copper is deposited per week by these dynamos.

Electric Tramcars and Locomotives.—The success of the trials of the electric locomotives, first run publicly by Messrs. Elwell-Parker on November 7th in Birmingham, and described in this journal, has led to very many enquiries and some very substantial orders. This company have now in hand orders for some eight thousand pounds' worth of storage cars and electric locomotives. A large part of these are, of course, electric locomotives for the Birmingham tramways; but a number of other tram lines are having cars fitted up, many of them being self-contained storage cars. Another use to which electric locomotives are being put is that of moving stores, etc., in the fortifications, and an order from Government for a locomotive for this purpose for Plymouth has been received. The motor is some 8 or 10 h.p., and will be used for transport of all kinds of stores; the great advantage being the absence of any emission of smoke or steam.

Southampton.—The borough surveyor of Southampton, Mr. W. B. G. Bennett, read a paper the other day at the meeting of the Association of Municipal Engineers held at Southampton, in which he referred to the experiment which he had been carrying out to utilise the waste heat from the refuse destructor, in order to produce electricity. At the present time the works are lighted with two arcs of 3,000 c.p. each and 12 incandescents, in addition to which four streets in the vicinity are frequently lighted for the information of the Corporation. So successful have been the results that the Corporation unanimously resolved to extend the installation to the Municipal Offices, the Hartley Institution, the Town Hall, etc. For this purpose accumulators will be used and charged by a cable. Mr. Bennett also referred to the experiment of Mr. Webster for the electrical treatment of sewage, and stated that when the system was perfect nothing would be easier than for them to try it.

Inductive Intoxication.—While Prof. Lodge has been showing the unexpected inductive effect of real and artificial lightning, the *Popular Scientific Monthly* points out that "Jersey Lightning," otherwise strong drink, sometimes exerts what may be termed inductive action upon men who have had the ground prepared in times gone by. Various cases are cited in which military men, or other old stagers now reformed from drinking habits, when in company with other boon companions at dinner, though not themselves drinking anything stronger than coffee or lemonade, have yet manifested distinct symptoms of drunkenness after some little time in company with their hilarious companions. One man, after twelve years sobriety, on a military excursion with a drinking company, became thoroughly intoxicated by induction, though drinking nothing but water, an event which was the subject of much comment and loss socially to him, though all with him knew he had touched no alcohol.

Lecture on Transmission of Energy.—At the Ipswich Scientific Society last week, Mr. W. B. Sisling, of Messrs. Laurence, Paris, and Scott, Limited, delivered a lecture on the "Transmission of Energy by Electricity." The lecturer described the various systems of transmitting

Digitized by Google

energy, and used as an illustration a certain diamond mine, whose nearest source of energy was a coal mine, separated from the diamond mine by 200 miles of waste country. Mr. Sisling pointed out the enormous expense of building a railway to convey the coal, but by using electricity the current could be sent through wires to work the diamond mine. This was exemplified by models on a small scale. The hall was lighted by incandescent lamps, the current for these and for driving the motors—shown in motion—being supplied from the central station of Messrs. Laurence, Paris, and Scott. Several questions were asked of the lecturer, and a hearty vote of thanks were accorded to him at the conclusion of the meeting.

Tramcar Etiquette.—With perfection in the power supplying the tramway services by the introduction of electric traction, tramcar directors might well also look to perfection in civility of the attendants. The German conductors seem models in this respect from the remarks in a recent article. "The German tramcar conductor is polite. When a passenger boards or leaves the car the conductor touches his hat and says 'Good day.' When he collects a fare he attracts the passenger's attention by saying 'please.' The German conductor is phenomenally patient with foreigners, and few have seen him ruffled in the long incidental explanations and arguments. He smiles good-naturedly at the babies when collecting the fares, and holds a guarding hand when the mother alights. His collar and cuffs are clean. His uniform is never ragged or greasy, nor are his boots unblacked. In fact, a German tramcar conductor is generally so mannerly, clean, and well dressed that he is a bit of a prince among his class of society."

Sprague Motors.—It is stated that the factory of the Sprague Electric Railway and Motor Company is overcrowded with orders for motors, both for stationary and railway work. The large number of railroad companies which have ordered the new 30 h.p. motor car equipment and improved Sprague motors, would have been sufficient alone to have kept the business of the Sprague Company devoted exclusively to that branch of the electric power field. But the attention of the Sprague Company has not been devoted entirely to this class of work. They have recently received a number of large orders for stationary motors, including one to operate a mill in Nebraska by electricity, using more than 100 h.p. of motors, with the generating station more than three miles away. In addition to this order, they have received a number of others for less individual capacity, but making a very large aggregate Several other mills have ordered complete electrical equipments, and a large number of orders for stationary motors have been sent in from all directions.

Sugar Refining by Electricity.—"Yet another, oh, my Friend!" No, not quite another, as the following method is expressly stated to have "nothing in common with that of Prof. Friend," of New York and—, well, say sorrowful memory. It has been dug out of the depths of the French Patent Office, where it was recently deposited by M. Bauder, and is founded upon a production of ozone by the combined action of steam and electricity. According to the description given of this method, the raw sugar is placed in a machine having a centrifugal action, and constructed with an hermetically sealed cover, through which the conducting wires are passed at short distances from each other. Steam is introduced, and when the sugar is sufficiently moistened, sparks are allowed to pass between the wires. The ozone liberated is said to refine the sugar. The syrup is separated by centrifugal force, and can be mixed with other raw sugar and again submitted to the same treatment. Might be termed refining by "faradisation." Mr. Wimshurst may be interested to hear this; but, we should suppose, no more shareholders.

Export Catalogue.—We have received a copy of the "Annual Export Catalogue of Machinery and Hardware" from the Machinery and Hardware Company, Limited, 147, Queen Victoria-street. It is simply a bound book of advertisements and price lists of specialities for the colonies and abroad, and includes the names of very many important English firms, and has brought satisfactory business from the most remote places abroad. The catalogue is published annually, and has a guaranteed free circulation of 10,000 copies. These are distributed throughout the home markets, to merchants, shippers, Chambers of Commerce, foreign Consuls and Ministers, and public works, etc.; but the bulk of them go to selected buyers in India, the colonies, and the continent generally. The present edition is sent to the United Kingdom, India, Australia, New Zealand, Canada, Germany, France, Italy, Austria, Spain, Russia, Norway, Sweden, Portugal, Greece, Denmark, Turkey, Egypt, Roumania, China, Japan, South American States, the Cape, Fiji, Tasmania, Morocco, Malta, Cyprus, etc. One edition is in English, one in Spanish, and one in German, and it should be useful to some of our readers who are sending goods abroad.

Aerial Wires in New York.—The war against overhead wires in New York has been carried forward through thick and thin—through telegraph and through electric light wires, that is. The *Scientific American* gives a graphic note upon the subject. "An attempt," it says, "on the part of the Western Union Telegraph Co., to obtain an injunction in the Federal courts having failed, the city authorities put a large force of men at work to cut and remove the wires and lower the poles. Unfortunately, the work has been marred by casualties, one instant death and several injuries resulting. One lineman, who had climbed a pole, narrowly escaped with his life, as the rotten wood gave way, and the pole, unbraced by the usual telegraph lines, fell. It fortunately struck against a building, so that the operative was afforded a chance of escape, which he was quick to profit by. This accident showed that the poles were a distinct source of danger as they became more and more decayed. A very impressive feature of the operations is the comparative darkness to which the city in these parts is relegated at night. The gas lamps are quite unable to supply sufficient light for the people, who have now been accustomed to electric illumination. It is to be hoped that the electric light companies will make every effort to start their lamps anew, and give the many centennial visitors a good illustration of subway electric supply and illumination."

Medical Electricity.—The "British Association of Medical Electricians," as Mr. C. B. Harness has named his society, has issued the first number of a *Journal*. The receipt of this paper led us to pay a visit to Mr. Harness' rooms to see what really there was to be seen, and whatever may be our strong opinions as to his electropathic belt and magnetic hairbrush, we must in justice say there can only be one opinion upon one portion of his apparatus—that of the Zander Institute of Swedish mechanical exercise machines. These are a marvel of ingenuity, both from an engineer's point of view, for the multitude of complicated

Digitized by Google

motions brought about, as well as from that of their adaptation to anatomy for the purpose of mechanically exercising limbs, and for treatment by massage, and no expense has evidently been spared in fitting up this department. Now, we can only say, after inspecting these massage machines, that if Mr. Harness would only give the order to fit up electrical apparatus in the same perfect and thorough manner for research by delicate electric testing of the human body, by someone really competent and on scientific grounds, he might yet do more good in medical electricity than the harm ascribed to him by the accumulation of lucre through the sale of high-priced warm flannel "electropathic" belts. Mr. Harness' views for the future appear to be enchantingly comprehensive. He will attempt to inaugurate a "new faculty" for the prosecution of the practice of medical electricity. He would found a free electropathic hospital, and join in a compact hitherto unachieved—by the help of his French doctors from the Salpêtrière—between anatomical science and electricity. Mr. Harness has now a fine Wimshurst machine, and gets very good sparks from it. He has also these fine massage machines, and some very elaborate and wonderful anatomical diagrams. Whenever he cares to spend his money by developing his electrical apparatus to any similar extent, we would again visit his palatial premises, and have, possibly, something to say on the utility or the reverse of his apparatus from an electrical point of view.

Electric Launches up the River.—Summer came in with a rush with the month of May this year, and boating was begun with great fervour last Sunday all the way up the River Thames. There is great talk this year amongst boating men of the introduction of electrical launches, and we hear that Messrs. Immisch have been far from idle—in fact, very busy in fitting up charging stations along the upper reaches. We believe there is to be one permanent charging station at Platt's Island, and three floating stations at points extending up to Maidenhead, with others to follow. It is open to conjecture how far the electric launch business will succeed, and we shall be extremely interested in the result of Messrs. Immisch's venture. Steam launches are a success because coal is cheap, and coal can be bought everywhere; whereas an electric launch cannot at present go more than a day's journey from the source of its power. Therefore, it is, that charging stations are a necessity. But independently of this, there is quite a limit to their use, though how far it may extend we cannot yet tell. But the bulk of boating men go boating, not for relaxation only, but relaxation of mind combined with exercise of body, and the fact that the work is done for you will by no means induce the bulk of boating people to go in for electric launches. The great advantages, however, of these over steam launches in the matter of smell and vibration, independently of the novelty of the thing, will doubtless cause large numbers of the present "launchers" to patronise electricity. One thing we should like to impress upon Messrs. Immisch and their engineers, who are engineers first, and boating men only as a mere detail. It is this, that before all things the greatest care should be taken not to disfigure the lovely banks of the Thames by uncouth engineering work, or blackened and smoke-belching machinery; nor to cut down trees or bushes, or otherwise destroy the beauty that is dear to the pleasure-seekers up the Thames. If the slightest cause of this kind is given for complaint, electric launches will come in for unthought-of opprobrium, for it will save nothing to make river locomotion easier, if the river itself is not worth going to see by reason of charging stations. However, "a word to the wise is enough," and we shall hope to have an opportunity soon this year of practically testing the delight of an electric day "up the river."

Royal Society Conversazione.—A most interesting meeting with exhibition of various apparatus took place at the Royal Society conversazione on Wednesday evening. Mr. C. V. Boys showed an experiment illustrating the insulating power of his quartz threads. Gold leaves were attached to a quartz rod drawn out fine for about an inch. The atmosphere was kept moist by a dish of water. A glass insulating stem would allow all the charge to escape in a second or two, but with the quartz very little change is observed for four or five hours. The quartz may even be dipped in water without apparently altering its insulation. Mr. R. A. Hadfield had a magnificent exhibit illustrating the non-magnetic properties of manganese steel. A number of strong horseshoe magnets were arranged over cups filled with filings from steel containing various percentages of manganese. The filings rose in a bunch in the centre of some of the cups, but gradually diminished until no effect was observed in the specimens containing over about 12 per cent. manganese. Capt. Holden exhibited a chronograph for measuring speed of projectiles, in which the shot, passing the screen, breaks an electric circuit, which holds up a copper tube screwed to an iron head. As this drops, the second screen lets a knife-edge fall in a similar manner, making a notch, and the length along the tube is a measure of the velocity. Capt. Holden also exhibited his hydrometer for secondary batteries, giving a range of about 7in. for difference in specific gravity of from 1·160 to 1·200. Pitkin and Niblett's firedamp meter, which we describe more in detail elsewhere, attracted a great deal of attention. The principle is simply that the occlusion of gas or explosive mixture on a suitably prepared bulb increases the temperature of one arm of a thermometer. Mr. Pitkin also exhibited his neat little pocket lamp of 1 c.p., weighing about 1¾lb. Mr. J. W. Swan had sent an interesting method of showing the effect of the earth's magnetism—a motor with Gramme ring, but without field-magnets other than N. and S. magnetic poles of the earth. The motor revolved with a current of ½ ampere in the armature. Mr. Shelford Bidwell showed the effect of light in magnetising iron. A bar after magnetisation by a current is partially demagnetised by a reversed current. When light is let fall upon the bar, it instantly deflects the magnetometer needle. Dr. Gore exhibited his voltaic balance for detecting very minute quantities in chemical analysis. Prof. W. N. Hartley showed numerous films on mica of various metals and metallic oxides in prismatic colours deposited by the electric spark. Mr. Muybridge showed his automatic electro-photographs of moving animals by the electric lantern, illustrating the various phases of locomotion. Mr. Eric Bruce attracted a great deal of attention by an "electro-graphoscope" showing the illusion obtained by the persistence of vision. A lantern was prepared with the figure of an angel and directed into space, and, of course, nothing could be seen. The electro-graphoscope consisted of a white lath of wood an inch wide and about 2ft. 6in. long, made to revolve very rapidly by an electromotor. When in motion, the effect is an almost invisible haze, but when the revolving lath is placed in the rays from the lantern the effect was as of a solid angel in relief suspended in mid-air, due to the persistence on the vision of minute fractions of the lantern image.

FIREDAMP METER.

At the Royal Society's Conversazione on Wednesday a new form of firedamp meter was exhibited by Messrs. Pitkin and Niblett, which promises to be very useful in conjunction with electric lighting in mining operations.

In its simplest form this instrument consists of two ordinary cylindrical bulbed thermometers graduated to the ordinary Fahrenheit scale, and mounted on a polished boxwood block. For their protection the thermometer stems are recessed into the wood frame. Slots going right through are made to receive the bulbs. These apertures are covered on both sides with fine wire gauze, held firmly on by brass frames. By this arrangement the bulbs are protected against dirt and accidental damage. The left-hand tube is the gas indicator. The right-hand stem merely serves as a temperature register of the surrounding air. When the instrument is placed in a mixture of certain explosive gases, such as ordinary coal-gas and air, or firedamp and air, an immediate rise in the mercury in the indicator stem is observed. This gradual rising goes on until it reaches a maximum, when, unless a continuous current of the mixed gases is caused to flow through the instrument, the mercury column will come to rest and then slowly subside. The percentage of the explosive gas in the mixture is estimated by taking the difference in degrees in the readings of the two scales when the indicator mercury is at its maximum. In one of the instruments tested a difference in the readings of

2 deg.	= 1	per cent.	of active gas
6 "	= 2	"	"
13 "	= 3	"	"
23 "	= 4	"	"
36 "	= 5	"	"
53 "	= 6	"	"
85 "	= 7	"	"

These readings point to a fairly definite law, except in the case of the last reading, when we must assume an error of observation, or some other error. From the other readings it will be seen that the second order of differences is constant.

On the scales one division represents two deg. F. Of course, each instrument will have to be calibrated, either from a standard or from a known mixture of gas.

In working out the above, that peculiar property of certain rare metals is made use of, which, when in a very finely-divided state, occlude and facilitate the chemical combination of oxygen and hydrogen, and also in some instances of oxygen and such unstable compounds of hydrogen, such as of coal gas and firedamp. Of these metals it is found that paladium, platinum, and iridium are the most energetic. Platinum-black or spongy platinum is perhaps the most readily obtained, and answers the purpose admirably, as in this instrument, if a bulb is covered with a thin layer of platinum-black, and is then subjected to the influence of any mixture of oxygen and hydrogen, chemical combination of the two gases takes place within the pores of the spongy metal. During the combination a considerable amount of heat is given out. This causes the rapid rise observable in the mercury column.

As the indicator answers well in mixtures of ordinary coal-gas and air, we think it might be of use in gas works, etc., where it could be used to detect leakages in pipe retorts and holders.

In an ordinary way, the instrument may be readily tested by holding it over a gas-burner and allowing the gas to impinge upon the wire gauze, or better still, a little gas may be collected in a glass jug or jar by upward displacement, and then inserting the meter so as to bring its bulbs within the influence of the gaseous mixture.

Various forms of the meter can be made—some of which we shall illustrate in our next issue. It can be easily applied to the electric miners' lamp, and, besides giving a visual indication by the rise of mercury or the motion of a pointer, can be made to give an aural one by means of a bell, the mercury or pointer making electrical contact to the bell when the mixture of gases approaches the dangerous state. Altogether, the instrument is very interesting, and promises to be of great practical utility.

THE CARSTAIRS ELECTRIC RAILWAY.

Messrs. Anderson and Munro, of Glasgow, are now putting the finishing touches to this, the first electric railway in Scotland. It extends from Carstairs House, the residence of Mr. Joseph Monteith, to Carstairs Junction on the Caledonian Railway System. It has been constructed chiefly as a means of rapid and always ready communication between the station and Mansion House; but it has branches and sidings, so that it may serve for local farm and estate traffic. The line runs for a mile and a quarter through some of the most beautiful scenery on the Carstairs estate, and with its narrow (30in.) gauge, flanked on either side by rows of neat ivory-coloured insulators, adds to the interest of the scene, while, owing to the absence of all smoke and dirt and noise, it will not in the least mar the charm of its surroundings. The conductors are rectangular rods of very pure iron, arranged the positive on the one side, the negative on the other, about a foot outside of the rails. The conductors are attached to specially designed insulators by an elastic steel fastening, which allows of no side shake, but permits the rods to expand freely, and which can be easily replaced should any insulator get broken. The insulators are in turn supported on iron rods, rising some 10in. from the sleepers to which they are attached. A handsome electric carriage is being constructed, and during the trial runs a speed of 35 miles an hour was attained, and could have been easily surpassed. At all speeds the motion was exceedingly smooth and pleasant.

The source of power is a waterfall three miles distant. When the car is at the station end, therefore, the current traverses eight and a half miles of conductor. As the Mansion House had to be lit throughout by the same current, and as it was necessary to keep the potential difference under 250 volts at railway to obviate danger from shock, and the size of conductor small on account of its length, it will be seen that a very pretty problem was presented for solution. Fortunately, there was ample water-power to waste, so a series-wound dynamo of Goolden type, giving 400 volts and about 40 amperes, was placed beside the turbine, and current was carried over the three miles to the Mansion House along four bare copper wires run on fluid insulators. "Earth" is nowhere used, the circuit being metallic and insulated throughout with a view to secure higher insulation, less danger of shock at the house and railway, a double chance against snow, and a circuit of constant resistance. At the Mansion House there is placed a battery of 100 E.P.S. cells, which are charged all in series. This battery when discharging has the house wires so joined up that one half supplies one section of the house and the other half another section, although, when lighting lamps only, it can be transformed into one battery of 100 volts, the two halves being then in parallel. The cars can be run from the cells alone, from the dynamo alone, or from both coupled. The varying demands for current produce large variations of field-magnet strength, and consequently of E.M.F. at the terminals of the series dynamo, but, on the other hand, the large line resistance causes fluctuations in the opposite direction in the amount of loss in the line. This loss varies from 0 up to 150 volts. The dynamo characteristic and the line resistance have been so adjusted that, within a working range of current strength, the potential difference at the house switchboard is approximately 250 volts. An automatic appliance keeps the current flowing always within the desired range, so that even if all load is thrown off there is not more than 250 volts on the railway conductors, nor are the field-magnets demagnetised. At present an attendant resident in the vicinity starts and stops the dynamo on receipt of signal, but it is the intention to put in a small motor to put off and on the water supply. A pair of little brushes will be placed midway on either side between the chief collecting brushes, and these little brushes coupled together are joined to the signalling wire after passing through the armature of little motor. The electromagnets of the motor are a shunt on the main wires. By joining the accumulator end of the signalling wire to the positive or negative wire respectively, a current flows through the small motor armature in one or the other

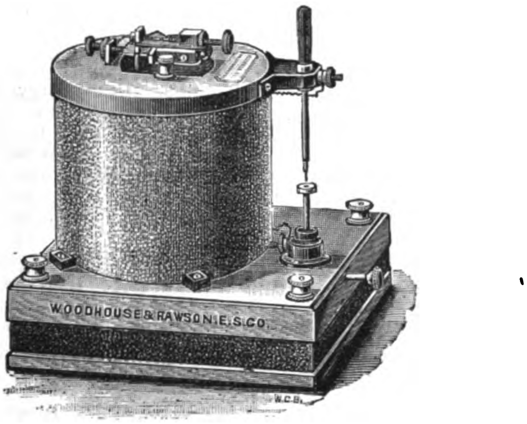
Digitized by Google

direction. Thus, by putting a switch at the house to right or to left, the water can be put off or on at the turbine three miles distant. We hope to give drawing of the car when it is completed, showing details of its mechanism. The whole system has been designed by Mr. John M. M. Munro (of Anderson and Munro, the contractors for the work), and carried out under his superintendence. Mr. Monteith, who is himself a skilful engineer, has taken a close personal interest in the construction of this railway, and with Mr. David Hunter, of Lanark, has materially assisted the progress and perfecting of the work.

PYKE AND BARNETT'S FLAME SPARK COIL, WITH CONTINUOUS ACTION RAPID BREAK.

Our readers will remember that, some time ago, we gave a short description of the above apparatus, and we now have pleasure in illustrating the commercial model of the invention at present made and stocked by Messrs. Woodhouse and Rawson. It will be seen from the woodcut that the design has been rendered more compact, and that the moving parts of the break (which is in the recessed centre of the coil) project above the topboard for ready adjustment.

The break is quite a new departure, and from its certainty of action, forms, perhaps, the most valuable improvement in these coils.



The principle of its action is as follows: a hammer, mounted on a short thick spring, is very rapidly and vigorously vibrated by means of an electromagnet included in a shunt circuit, and the main or coil contacts are so arranged that (one of them being mounted on a spring) on the recoil of the vibrating hammer it strikes against the movable main contact, and causes a slight and instant separation. The whole of the parts are arranged for ready and rapid adjustment, and the flat contacts are arranged on screws, which are readily removable for replatinising. The arrangement of the dischargers is also very neat and not so liable to damage as the old style. The size of the coil, No. 1, is 5in. diameter by $4\frac{5}{8}$in. high. Another size of this convenient high-tension current generator will be shortly procurable.

SECONDARY BATTERIES.*

BY WILLIAM HENRY PREECE, F.R.S.

Secondary batteries are often called accumulators and storage batteries, and the general impression is that they accumulate or store that which is called "electricity." What is accumulated or stored is, however, energy in its chemical form. A *secondary* battery is really a battery pure and simple, but it differs from a *primary* battery in this that the chemical character of the conductors or plates, and the electrolyte in which they are immersed, has been excited by an electric current which has passed through them continuously for some time; while in a primary battery the chemical affinities exist in the materials of which the cell is composed. In the language of the distinguished American, Judge Coxe, "A secondary battery is one which gives no electricity of itself, but is active only when rendered so by a current from an independent source."

Secondary batteries have become an essential feature of every properly equipped isolated electric light installation, not only for the regulation of electric currents, and the maintenance of uniform E.M.F., but to give a store of energy to draw upon at night, and when any accident or failure occurs. They are also employed for the distribution of electrical energy from central stations. They are used for ship and for train lighting, and they seemed destined to solve the important question of economical traction on our tramways. They are much used in telegraphy. They have passed through a very severe ordeal of seven years' practical development in the face of determined opposition, and in spite of the prejudice resulting from disastrous commercial speculations, and from the non-fulfilment of over-sanguine hopes and hasty utilitarian anticipations.

The father of lead secondary batteries, in a scientific sense, is the eminent French electrician, Gaston Planté, but the final stroke that made the apparatus a real practical instrument was the discovery of Faure, who showed that the application of oxides of lead, in the form of a paste or cement on the surface of the lead supports, so hastened the process of formation of the plates that the battery was made a commercial and valuable instrument. Sellon, Volkmar, Swan, Julien, Parker, King, Drake, and Gorham have added so much to the mechanical details, and have done so much to remedy defects and remove faults of construction, that all we want now is to crystalise into practical language the teachings of experience.

My house has been lighted by these batteries since March, 1884, now five years ago. I commenced with 17 Planté cells, manufactured by Elwell, Parker, and Co., of Wolverhampton, charged by currents from a dynamo driven by a 2 h.p. gas-engine, but after two years of experimenting I selected 26 cells of the 15 L E.P.S. type, with which form of cells I am now working. Their value can be illustrated by the following fact: On March 30 my gas-engine broke down. I quite forgot to give notice to the makers to send down men to repair it until six days had elapsed. It took five more days to repair the engine, so that for eleven days I had not been able to recharge the cells; but during all these days the light never failed, and we were not in any way inconvenienced. The useful capacity of my cells is 330 ampere-hours, and my nightly consumption is now about 30 ampere-hours. This was a very good test of the efficiency of the cells, for I obtained from them nearly all the energy they could usefully give. Only two cells were really exhausted during this time, but as I had two spare cells to replace them, their exhaustion did not cause me any inconvenience. The E.M.F. fell to 1·8 per cell, and the light in consequence was not so brilliant as usual. A good practical test of the efficiency of a battery like this is better than any isolated tests on single cells.

The illumination of this hall (Society of Arts) is regulated by 58 E.P.S. cells, of 13 L type, an obsolete, which are used, when the hall is not open, to light the secretary's and the public offices. They have been at work there since January, 1885, and have given no trouble and very great satisfaction.

Types of Cell.

There are several kinds and types of cells in use at the present day, but the principal ones supplied in England are by the Electrical Power Storage Company and by Elwell-Parker Company, Limited. The E.P.S. cells are of several patterns: "L."—Stationary cells used for electric lighting motive-power, and general purposes. "T."—Portable cells used for tramcar and launch propulsion. "C."—Portable cells used for railway carriage lighting.

Of the "L" pattern the following are the sizes issued:

No. of plates.	Weight.	Maximum rate of discharge (amperes).	No. of 10-candle power lamps (26 cells).	Capacity (ampere-hours).
	lb.			
7 L	68	13	21	130
11 L	101	22	36	220
15 L	128	30	50	330
23 L	211	47	76	500
31 L	265	64	100	660

There are always one more negative plate than positive.

E.P.S. Type, 1888.

The plates of each cell are divided into the positive and the negative, in each case a pure lead grid being cast for retaining the paste-oxide $8\frac{1}{4}$ by $9\frac{1}{4}$ by $\frac{1}{16}$ thick, and weighing 5lb. The perforations or openings of the positive plate are filled with minium, while those of the negative plates are filled with litharge. The plates so prepared are then subjected to powerful currents for several hours, when the litharge (PbO) is reduced to spongy lead (Pb), and the minium and red lead (Pb_3O_4) become lead peroxide (PbO_2). There is thus economy in reducing the lower oxide and in peroxidising the higher one. Many attempts have been made to manufacture the grids of inoxidisable alloys, such as an alloy of antimony and lead, to which mercury is sometimes added, but so far nothing seems to be superior to the pure lead itself. The principal defect has been that of buckling or deforming, and this is supposed to be due to irregular oxidisation, but no clear explanation has yet been given of the remarkable way in which lead plates curl and curve under the influence of electrolysis. Plates do not buckle when they are properly treated. It is the rough handling of cells—calling upon them to do more than they were designed for—neglecting to maintain the level of the liquid and its density that principally lead to deformation, disintegration, and also short-circuiting from the paste falling out in

* Paper read before the Society of Arts, May 1. This subject has been before the society on two occasions. In 1881 (vol. xxx., p. 30) Prof. Silvanus Thompson read a paper on the "Storage of Electricity"; and in 1883 (vol. xxxi., pp. 1,025, 1,038), Prof. Oliver Lodge, F.R.S., gave two lectures on "Secondary Batteries."

Digitized by Google

lugs and resting across the plates. The plates are now fixed ⅜ths of an inch apart, a sufficient distance to allow any pellet that may fall out to drop harmlessly to the bottom of the cell. This distance can be increased with advantage.

The pellets of paste are now made considerably smaller than was the case at first, and this has been done to hasten the period of formation, and to render the whole of the pellet active, which was not always the case with the larger pellet, for the centres were often found unformed, and therefore idle.

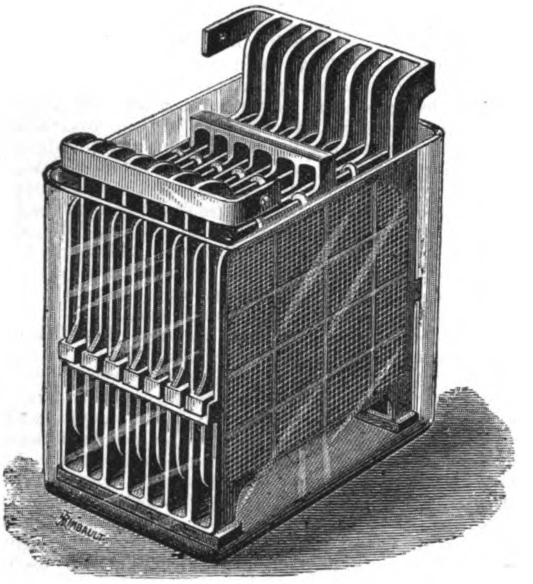


Fig. 1.

The negative plates of each cell rest on toes or blocks, and are maintained 1½in. clear of the bottom of the cell, and they suspend the positive plates by lead bars running along each side of the negative section, on which ebonite supports carry the positives. All the plates of each kind of each cell are welded or burnt on to a broad lead strip, to which either a terminal is attached, or which is burnt on to the strip of the next cell.

The "L" cells, for fixed permanent installations, are of glass, but for ship, tram, and train purposes they are generally fixed in wooden boxes, rendered water-tight by lead, marine glue, or ebonite linings.

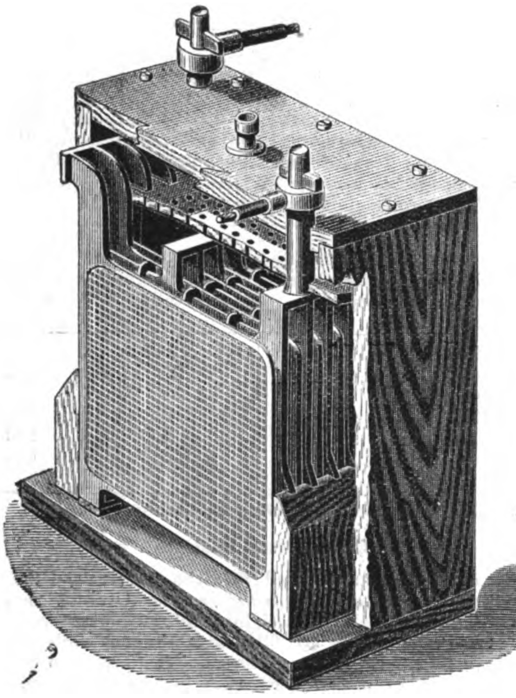

Fig. 2.

Glass is much preferable to wood, or to any opaque substance, for it is very useful to see how the plates and their packing are behaving. Elwell-Parker introduced a cell made of an in oxidisable alloy, but it has not been received with favour.

Glass has this advantage, that it is an excellent insulator, though owing to its hygroscopic tendency it has been found necessary in some cases to mount the cells on oil cups—a plan that is always necessary with wood and metal boxes.

The electrical leakage from glass cells when the acid spray is checked is very small indeed. They retain their charge unimpaired for months. It is, however, a good plan to paint the glass over with paraffin or vaseline occasionally. It checks leakage, and prevents the acid from creeping.

Elwell-Parker Cell.

The form of cell supplied by Elwell-Parker differs in several details from the E.P.S. pattern, though it is of the same type. The plates are held together by side frames of wood or vulcanite at the edges, so as to knit them together very firmly and prevent buckling. The whole frame of the largest size can be lifted in and out by a crane with ease. The negative plates are made in a way which prevents blistering, a defect in the E.P.S. plates, and the grids are burred in a way which prevents the pellets from dropping out. This process, due to Messrs. Drake and Gorham, is an important improvement.

Charging.

A diagram is now shown indicating the performance of 24 new E.P.S. cells when freshly supplied with sulphuric acid solution of 1·155 to 1·160 density, and charged by current for the first time. It will be seen that 39 hours and an average of 30 amperes were spent in bringing them up to the mark. Thus 1·170 ampere-hours were expended in the first charge. It is curious to observe how the density fell owing to the formation of lead sulphate. The cells rested during the night. Only four cells are shown as regards density, but they were all carefully measured by hydrometer. Gladstone and Tribe* have taught us that the principal chemical change that goes on in the cell is the gradual formation and reduction of lead sulphate $(Pb\,So_4)$, and the various changes that occur in the density of the electrolyte are due to these operations.

Capacity.

The capacity of a cell is the amount of energy it will accumulate and usefully restore. It is measured roughly either in ampere-hours or in watt-hours. The latter is the more accurate if the fall of E.M.F. is carefully noted, but if the E.M.F. is maintained fairly constant by not running the cells too low, the former is equally practical and more common. The average type of cell, such as the stationary E.P.S. pattern, gives a useful capacity of 4 ampere-hours per lb. of plates complete. I have had a cell (Fitzgerald's lithanode) which gave a return as high as 5·7 ampere-hours per lb., while the Planté type rarely exceed 2 ampere-hours per lb. The portable form used for traction purposes gives 5 ampere-hours per lb., but this is only because the plates are much lighter.

Efficiency.

The efficiency of a cell is the ratio between the energy taken out of it to the energy put into it, and the useful efficiency is usually taken from the number of ampere-hours discharged when the E.M.F. falls 10 per cent. in magnitude. This figure is a very variable quantity, for it depends very much on the current density—that is, upon the number of amperes per unit of surface—one square centimetre—of plate. The following experiment on a small cell illustrates this point:

Current density.	Ampere-hours.
·013	44·6
·048	36·5
·09	30·2

The ordinary current density, which should not be exceeded in practice, is ·01. This means that the maximum output should not exceed 4 amperes per positive plate.

A cell will discharge many more ampere-hours than are given by this useful efficiency, and if the discharge be taken with a very small density, the efficiency may reach a very high figure. Thus 95 and 98 per cent. have been obtained from small cells slowly discharged. The efficiency of a cell therefore varies with its rate of discharge. If the efficiency, with an output of 5 amperes, be 90 per cent., it will be only 50 per cent. with a discharge of 40 amperes. Batteries drop in E.M.F. if the rate of discharge is high, or the current density great. They should therefore be discharged at a slow rate. The most general maximum rate is found to be that which discharges a cell in ten hours. Thus, the discharge of 15 L cells should not exceed 30 amperes, nor that of 31 L cells 60 amperes.

It is sometimes thought that because the E.M.F. in charging is 25 per cent. greater than in discharging, there must be a loss of energy to that amount, but the fact is this loss of E.M.F. is compensated for by gain of current, owing to the reduction in the internal resistance of the cell. The internal resistance of a cell, which is normally about $\cdot0003\omega$ per positive plate, diminishes with the strength of the current of discharge, and therefore it is possible to get nearly all of the energy out of a cell that has been put into it. The efficiency of a secondary battery increases with the lightness of the load put upon it, and in this respect it possesses a great advantage over that other transformer of electric energy—namely, the secondary generator of Gaulard.

It has been the practice to place the plates in a cell very much too close to each other. This not only favours short-circuiting, but it prevents the free circulation of the electrolyte. Recent experiments have also shown that efficiency has also been improved by increasing the distance between the plates. I exhibit a diagram, through the kindness of Mr. King, illustrating this useful fact—a fact fully confirmed by my own experience with Planté cells.

The Electrolyte.

The character and the quality of the electrolyte used in secondary cells has scarcely received the attention it deserves. Hitherto scarcely anything but a solution of sulphuric acid has been employed. Experience seems to show that the best solution to use before charging is one which has a density of 1·150. Such a solution in a 15 L cell, when fully charged, will acquire a density of from 1·210 to 1·220, and it is customary to maintain the density of the cells somewhat between 1·170 and the higher figure. One of the great troubles with secondary cells that are imperfectly and improperly

* "The Chemistry of the Secondary Batteries of Planté and Faure," by J. H. Gladstone and Alfred Tribe. "Nature Series," Macmillan.

treated is the formation of the white sulphate of lead that is frequently seen upon both plates. In fact, it is the root of nearly all the ills that these cells are heir to. There are many ways of getting rid of this sulphating. The plan used by Mr. Sayers, the engineer in charge of the St. Pancras Hotel installation, is described by him as follows:

"Our battery of 120 15 L cells was rather badly covered with sulphate of lead. At first I simply charged them with the ordinary maximum charging current—30 amperes—when each cell, on becoming full, would give about 2·5 volts. The sulphate, however, did not apparently move. I then tried charging with 40 or 45 amperes for a few weeks, and the change in the look of the plates—of the peroxide plate chiefly—was considerable. They began to exhibit patches of the well-known plum-coloured peroxide, and nearly all had the appearance of a peroxide plate covered with a lace-work of sulphate of lead. This lace-work, also, soon nearly entirely disappeared, and the majority of the plates are now looking very well. The E.M.F. of each cell, with 40 amperes charging current, is about 2·7 volts when the cell is milky. I have thought that this result was due either to the fact—if it is a fact—that sulphate of lead required more than 2·5 volts to decompose it thoroughly, say 2·6 volts, or, that the large quantities of nascent hydrogen attack the sulphate and combine, making sulphuric acid and lead."

It occurred, however, in 1886, to Mr. Barber-Starkey, of Aldenham Park, near Bridgnorth, to see if carbonate of soda, in the presence of lead, had any beneficial effect upon plates liable to sulphating. The result was very satisfactory, all traces of sulphating disappeared. He treated his own cells in this way, and the effect was so decidedly advantageous to all appearances, that I determined, after careful inspection and enquiry, to make an exhaustive experiment that should determine the question, and at the same time settle the best proportion to use. Six new 15 L cells of the Elwell-Parker make were taken, and they were charged with solutions in the following manner: No. 1—5 pints of sulphuric acid, 5 pints of sulphate of sodium, 15 pints of water; No. 2—5 pints of sulphuric acid, 4 pints of sulphate of sodium, 16 pints of water; No. 3—5 pints of sulphuric acid, 3 pints of sulphate of sodium, 17 pints of water; No. 4—5 pints of sulphuric acid, 2 pints of sulphate of sodium, 18 pints of water; No. 5—5 pints of sulphuric acid, 1 pint of sulphate of sodium, 19 pints of water; No. 6—5 pints of sulphuric acid to 20 pints of water.

The sulphate of sodium solution was prepared by first making a saturated solution of carbonate of soda (ordinary washing soda), and then adding thereto sulphuric acid until effervescence ceased. The cells so prepared have been charged and discharged, and watched with great care from May 1, 1888, until the present day. We therefore have exactly 12 months' experience of their behaviour, and there can be no doubt as to the beneficial result. The solution marked No. 5 is that which has given the best results, and after about six months' experience of its behaviour two complete sets of 52 No. 23 L cells were charged, the one with the ordinary sulphuric acid solution of 1·175 density, and the other with sulphate of sodium solution of 1·225 density. Six months' experience of these two sets has confirmed the result that immense benefit is to be derived from the sulphate of sodium solution. There has been no evidence of buckling, there has been little or no scaling. The bottom of the cells are nearly as clean as when they were first charged, while the bottom of those charged with the sulphuric acid solution have the usual accumulation of oxides of lead. Two cells were also, and at the same time, charged, the one with the sulphuric acid, and the other with the sodium solution, and very careful tests of these two cells show that the addition of soda does not impair either the E.M.F. or the internal resistance, nor does it diminish the output of the cells. I have, therefore, come to the conclusion that the addition of soda has a distinct beneficial result, and it is my intention to use it invariably in future. The cells so provided remain in splendid condition. They can be left for months without developing any trace of sulphating or even of loss of charge. Carbonate of soda thrown into a badly sulphated cell unquestionably leads to the rapid removal of the sulphate of lead, and always produces beautiful deep puce-coloured peroxide of lead.

Mr. R. Davids writes, January 18, 1889, to me from Campinas, Brazil: "As might have been expected, the cells (which had been delayed in transit) were very badly sulphated, but after 24 hours charging, I gave them a dose of soda, which proved a *santo remedio.*"

The electrolyte that I recommend for adoption is this: To a quart of saturated carbonate of soda solution add slowly, during continuous agitation, 12 fluid ounces of strong sulphuric acid; fill the cell with water 19 parts, strong sulphuric acid 5 parts, soda solution 1 part; total 25 parts. The specific gravity of this electrolyte should be 1·210.

It is a mistake to use cells of too small a capacity for stationary purposes. This is usually done for economical reasons, owing to the capital expenditure involved in purchasing cells. Twenty-six 15 L cells cost £78, and the same number of 23 L cells cost £117, and I believe it to be true economy to expend the additional £39. Greater efficiency is obtained out of the larger cells now that soda has prevented injurious sulphating, for you are not limited to a minimum current as you are with the sulphuric acid solution. Small charging and discharging currents mean not only greater efficiency, but greater durability of the plates. Secondary batteries used for telegraphy show no sign of disintegration. It is over-taxing cells that destroys the plates. Mr. Barber Starkey's cells at Aldenham Park have now been in use for three years, and to all appearances they are quite as perfect now as when first set up.

Maintenance.

The chief secret of the successful working of a set of secondary cells is careful and regular attention to their behaviour, and the immediate remedy of any defect that may develop. They require daily testing and inspection. My battery is tested every morning for E.M.F. by means of a Cardew's voltmeter. If the total number of volts divided by the number of cells is not over 2 per cent., each cell is tested separately by a portable Walsall voltmeter graduated to tenths of a volt, until the defective cell is found. This has very rarely happened, in fact, only once during the past 12 months, when a plugging fell out, rested between the two plates, and short-circuited the cell.

Six cells are also tested every morning for density by a hydrometer, which is recorded in a book. The six cells are changed every month, so that each cell of the battery passes through this ordeal three times a year. The regular rise and fall of the specific gravity of a cell is the very best criterion one can have of its good working. I cannot do better than transcribe the record of one week's testing (see table A.)

Table A.—"Gothic Lodge" Engine-room. 28 E.P.S. Cells.

Date.	Current.	E.M.F.	Cells (Density).*

April 28 ...	—	57·5	1,210	1,205	1,195	1,225	1,225
" 29	—	57·4	1,205	1,200	1,190	1,220	1,220

* The density of the cells requires to be equalised periodically.

The normal density when the cells are charged should be 1·220. They fall 1 for every 5 ampere-hours taken out, and when they reach 1·150 they are exhausted. The density is thus a record of the energy that has been taken out, and of that which remains in.

Occasionally, I test them for internal resistance (ρ), both when charging and discharging. In the latter case the discharge current into the house is regulated by lamps to give 10 amperes when the E.M.F. (E_1) at the terminals is read. The E.M.F., when the ends are free (E_2), is also read. Then,

$$\frac{E_2 - E_1}{10} = \rho$$

I make the current 10, for the internal resistance varies with the current,* and by always using the same current I have an accurate comparison. The internal resistance of my 15 L cells is usually ·0012 ohm per cell when discharging, and ·005 when being charged.

When a cell becomes defective by short-circuiting, or any other cause, the plates are taken out, their faces scraped and straightened, the solution cleared, and the cell thoroughly cleaned. The cell is always benefited by such a process, for the cleaned cell is always the first to come up to the charge by as much as 1½ hour.

The cells in this building have been very carefully tended during the four years they have been at work. Only three sets of positive plates have been renewed.

In charging cells, there are three distinct indications that the cell is fully charged: 1. The E.M.F. suddenly rises up to 2·5 volts per cell. 2. The hydrometer indicates 1·220. 3. The electrolyte becomes milky by the fine bubbles of gas that float in the disturbed solution during their gradual ascent to the surface, and escape into the air.

The rise of bubbles of gas to the surface, and their bursting, scattered a considerable amount of acid spray about in the battery-room, which was injurious to metals and apparatus; but Mr. F. Higgins, M.I.E.E., showed how to prevent this by covering the cell with a fine net or with calico. Glass plates are now much used instead of calico, but I have adopted Mr. Henry Edmunds' plan of pouring upon the surface of the solution melted paraffin, which solidifies and coats the surface with a uniform thin layer of what looks like ice. A hole is bored to admit the hydrometer, and to allow any gases to escape.

It is necessary to be cautious in approaching cells with naked lights when they are being charged. There are several instances of explosion and injury to person in consequence. Two cases in London and two in Leeds have come under my own notice; one was in the Post Office.

The chief defect of the negative plate is that the plugging scales and falls off in thin flakes. This, in the recent types, falls harmlessly to the bottom, but it should not happen at all, and it is due either to imperfect material or to hasty formation. The negative plate should certainly last for ten years. The positive plates also disintegrate, and to a much greater extent. The disintegration of the lead peroxide seems to be necessary consequence of the action of the cell. It varies with the rate of discharge. If the cells be worked heavily it occurs rapidly, but if the maximum rate of the output of about four amperes per plate be adhered to, the duration of the plate may be taken to be three years. The decay of the positive plate seems to occur almost entirely in the lower half of the plate, and this is probably due to the greater density of the solution favouring unequal distribution of current.

(To be concluded).

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

Although the Paris Exhibition is open, the major portion of the exhibits are in so backward a state that any systematic description is almost impossible at present, so we shall wait a short time till the chaos of packing cases becomes a neat arrangement of exhibits. It is needless to tell our readers that—so far as our description of the electrical exhibits is concerned—our attention will, in the first place, be directed to the interests of English and American exhibitors. A special edition of this paper, with the report of the exhibition in two languages—English and French—will be obtainable in the Exhibition.

THE MINER'S LAMP.

The conversazione of the Royal Society not infrequently brings into notice apparatus of a very interesting character, and more especially devised for use in purely experimental work. Occasionally, however, apparatus of wider utility is shown, and that seems to have been the case this year, when Pitkin and Niblett's gas detectors were shown. Two directions have long been invitingly open to electrical inventors, and both now seem in a fair way to be filled. Ganz and Co. promise an alternate current motor, and the invention to which we now direct attention appears to offer a better solution to another problem than anything that has gone before. The miner's life at its best is a hard one, the dangers he braves and the work he does are but inadequately rewarded. There is a vast and profitable field for the use of any invention that will assist to ease the labour and reduce the danger. Such an invention many see in the application of electricity to miners' lamps. The requirements of a perfect miner's lamp, however, are not easily met, and work in the direction of supplying such lamps has not moved proportionally to the supply of electrical apparatus for lighting purposes in other directions, such, for example, as ship lighting. The miner's lamp must be cheap, not too heavy, certain in its action, capable of giving its light over a long period of time, safe from the possibility of igniting the firedamp, and able to indicate the presence of inflammable gases in dangerous quantities.

A number of lamps, actuated by primary or secondary batteries, have been devised, but none so far possess all the requisite qualities to enable one to say, this is the ideal lamp. Some of those in the market are ingenious and beautiful productions. Mr. Swan, seeing the absolute necessity of a gas detector, has added such to his lamp, but it has one great objection in that it is not automatic in its action. The miner at the face of the coal has to leave off his work, and manipulate the apparatus in order to see the state of the air in the working. As a matter of fact, the men cannot be expected to do this; their whole attention is required by their work, and time cannot be wasted in manipulating even the simplest apparatus. Otherwise, we have looked upon Mr. Swan's device as exceedingly ingenious. Whether Messrs. Pitkin and Niblett have solved the question we cannot say—to our mind the arrangement promises fairly—and we should require to know the results of a number of crucial experiments before giving adhesion to its perfection. The inventors are more deeply interested in studying the instrument than outsiders, and may, perhaps, at once be able to answer satisfactorily the questions which arise. In the first place, the instrument consists of two thermometers, one of which gives the ordinary reading due to the temperature of the air in contact with

the bulb, the other gives a reading due to heat development caused by the gaseous mixture in which it is placed acting upon spongy platinum or some similar metal—the precise chemist might say, through the action of the spongy platinum bringing about chemical combinations of some of the constituents of the mixture. Platinum has a remarkable power of causing the combination of oxygen with hydrogen and other combustible gases. "This property is exhibited even by a clean surface of platinum, in a greater degree by platinum in the spongy state, and most of all by the extremely divided form of the metal called platinum-black," *vide* Watts' Dict., vol. iv., p. 665. Now, if one of the thermometer bulbs is coated with platinum-black, and the platinum-black has the power to cause the combination of oxygen with the inflammable gas in a mine, thereby heating the platinum-black, the mercury will rise in the thermometer. If the heating thus effected is in proportion to the percentage of inflammable gas, then the rise of mercury will be proportional to that percentage. At this point an exceedingly grave question comes in. We assume that up to a certain point the heat of combination is used in heating the metals, and will not tend to ignite the surrounding inflammable mixture—in fact, that the spongy platinum acts like the gauze of a Davy lamp; but is not a point soon reached, when the temperature of the small quantity of spongy platinum used is sufficiently high to cause general combination. In other words, does it not again act like a Davy lamp, which, as is well known, may get too hot to be safe? Then, again, it must be ascertained whether the spongy platinum deteriorates in action, or whether it gets tired, and how, if it gets tired, the fact may be known to the lamp-minder. Again, is its action continuous—that is, if placed in a mixture, will it continuously indicate the presence of the adulterant gas, or will it indicate but momentarily or shortly?

The instrument can be made in a variety of forms. A suggested use, which commends itself to us, if the above questions are answered satisfactorily, is to fix it behind the incandescent lamp of the miner's lamp, making the dial of the instrument the reflector of the lamp, with the dark pointer across the dial. Every glance at the lamp would show the position of the pointer and the condition of the mine. A small bell could also be affixed to the lamp, and when mercury or pointer came to "danger signal," contact could be made, and the bell would ring out its warning sound. This might prove more useful than a pointer, because the miner might be too intent on his work to notice the position of the pointer, or a sudden influx of gas cause danger when a moment before there was no danger. The ringing of the bell would hardly fail to attract attention.

We have still one more question to ask. It is evident the action of this instrument is limited in range. Taking it that the inflammable gas in a mine is marsh gas ($C H_4$), and that it requires ten times its volume of air to cause an explosive mixture, or, as the miner would put it, five volumes to become dangerous, the range required through which an instrument must be effective, is soon ascertained. Have the inventors determined the range? These are a few of the questions which present themselves upon the introduction of this instrument. For the sake of the miners we sincerely hope that it is perfect, or can be made perfect. Combined with an electric lamp, it would give a more effective lamp than any at present used, and the introduction of such a combination into our mines would be exceedingly rapid. It must not be for a moment supposed that miners or owners object to the introduction of better lighting. They do not; both men and masters are anxious for it, but they will not accept the imperfect lamps that have hitherto been put forward as substitutes for the Davy, Clany, or other forms.

THE EFFICIENCY OF METHODS OF ARTIFICIAL ILLUMINATION.*

BY EDWARD L. NICHOLS, PROF. OF PHYSICS IN CORNELL UNIVERSITY.

(Continued from page 353.)

The curve of luminous radiation corresponds in form with that of candle-power. The distribution of total radiation, however, differs widely from these and the ratio, $\frac{\text{luminous energy}}{\text{total energy}}$, is a function of the angle which the line of measurement makes with the horizontal plane. The values of the efficiency in the case in question for the various angles at which measurements were made, are given in table III. They form the basis for the curve in Fig. 6, which is the diagram of efficiencies of the arc light under the conditions of operation already stated.

TABLE III.

Efficiency of an arc lamp; after measurements by H. Nakano:

Angle.	Efficiency = $\frac{\text{Luminous radiation}}{\text{Total radiation}}$
0°	·0548
10°	·0901
20°	·1228
30°	·1506
40°	·1552
50°	·1059
60°	·0676
63°	·0492

The integration of these values gives as the mean efficiency of the arc lamp in question, ·104, or 10·4 per cent.

The ratio of the radii of two semi-circles, the areas of which equal the areas enclosed by the curves of luminous and total radiation, gives us a measure of the "mean spherical" efficiency of the lamp. This ratio in the case of the lamp to which these curves refer is very much smaller than the generally accepted values of the efficiency of arc lamps, expressed in terms of the candle-power per watt, would lead us to expect. The intensity of the arc is, however, seldom expressed in mean spherical candles, and there are few data relating to the candle-power of this source of light upon which to found satisfactory estimates. On the one hand

* A paper read before the American Institute of Electrical Engineers, March 12, 1889.

Digitized by Google

we find it stated, doubtless correctly, that the mean light-producing efficiency of the 11 dynamos tested at the International Health Exhibition, held in London in 1884, was 1,440 candles per horse-power,* while the glow lamps only yielded 175 candles, and it is with estimates similar to the above with which we have generally to satisfy ourselves in comparing arc and incandescent systems of illumination.

For the purpose of deciding whether the results of Nakano's method of determining the ratio of luminous to total radiation are compatible with our other sources of knowledge concerning the arc light, we must make use of mean spherical candle-power as our basis of comparison.

Very careful measurements of the mean spherical candle-power of two arc lamps of representative and successful commercial types were made in the physical laboratory of Cornell University,† following the method of the Franklin Institute committee. Both of these lamps were rated at 2,000 c.p. They were maintained by dynamos of the types for which they had been especially designed, working under normal conditions. One of the lamps gave a mean spherical c.p. of 295, when working in series with nine other lamps of the same construction. When placed in circuit alone the c.p. rose to 348. The energy expended in the lamp in each case was 550 watts, and the efficiency accordingly 1·8 watts and 1·6 watts per candle.

The other lamp was found to reach 609 mean spherical candles at the cost of 601 watts. An inspection of the result obtained by the Franklin Institute committee would lead us to regard these as extreme values, between which the performance of almost all arc light would lie as a rule, nearer the lower than the upper of these limits. The efficiency of arc lights, then, expressed in mean spherical candle-power per watt is frequently as low as 1·5 times that of the incandescent lamp, and rarely three times as high. Now, the mean efficiency of the arc lamp under discussion, *i.e.*, the ratio, $\frac{\text{luminous radiation}}{\text{total radiation}}$, according to the measurements of Mr. Nakano, is almost exactly 10 per cent. The efficiency of incandescent lamps, defined in the same way, according to Mr. Merritt, may, as we have seen, be taken at about 5 per cent. The ratio is 2:1 in favour of the arc lamp which lies within the limits determined by comparison of candle-power and watts.

Small as these values for the efficiency of the electric light are, they show marked improvement over the efficiency determined in a similar manner for sources of illumination which depend upon the incandescence of carbon by direct combustion. More than a quarter of a century ago, Julius Thomsen‡ presented before a gathering of Swedish men of science the results of an investigation of the energy consumed in the sperm candle, and in various oil and gas flames. His memoir bore the suggestive title of the "Mechanical Equivalent of Light," and is one of the earliest contributions to our knowledge of the energy of luminous radiation.

The instruments employed in Thomsen's experiments were the thermopile and galvanometer, the indications of which were reduced to absolute measure by determination of the deflection produced by the radiation from a glass globe filled with hot water. The total loss of heat by radiation which this globe suffered was calculated from its rate of cooling, using Dulong and Petit's law. The water equivalent of the globe was 1,351 grains; its total loss of heat per minute at 50deg. C. was 250 calories; its loss of heat by radiation at the above temperature, when the air of the room was at 17deg., was 102 calories per minute. Under these conditions the influence of the globe of water upon the thermopile placed at a given distance, was observed. A luminous body having been substituted for the globe, its influence on the pile was likewise noted, and its total radiations in calories calculated by comparison of the deflections produced in the two cases.

For a sperm candle burning 8·2 grains per hour, the total radiation estimated by this method was 210 calories per minute. Other flames gave out proportions of heat nearly in proportion to their candle-power, as will be seen by inspection of table IV.

TABLE IV.

Calories per candle-power radiated by various flames, according to Julius Thomsen:

Source of illumination.	Candle-power.	Calories per candle.
Sperm candle	1·	210
Gas flame	1·2	201
Gas flame	7·7	199
Moderator lamp	8·6	199

The luminous energy was obtained by a method similar to that pursued by Merritt in the experiments already described. A bath containing a layer of water 20 c.m. in thickness was interposed between the lamp and the thermopile, and the indications of the galvanometer noted. The results were based upon the assumption that the cell absorbed 13 per cent. of the light and all of the dark rays. This estimate is doubtless faulty, and may involve a reduction of several per cent. from the values given by Thomsen. His results, uncorrected, are as follows:

TABLE V.

Energy of luminous radiation of various flames in calories, according to Julius Thomsen.

Source.	Candle-power.	Luminous energy. per c.p.
Candles	1·	4·4 calories.
Moderator lamp	6·25	3·9 calories.
Moderator lamp	8·6	4·1 calories.
Gas	7·7	4·2 calories.
Gas	1·2	3·7 calories.

The enery of the light-giving rays per candle-power of light produced is then, according to Thomsen, very nearly the same for the flames of the candle, oil lamp, and gas-burner. This conclusion has been abundantly confirmed by spectro-photometric observations of the quality of the light which they emit. It appears, moreover, from these observations, of which I shall have occasion to speak at length presently, that the temperature of the incandescent particles in such flames agrees very closely indeed with that of an incandescent lamp, consuming 5 watts at 16 c.p., being, as a rule, lower rather than higher than the latter; and the calculation of the energy of such a lamp in calories per minute, making use of the data furnished us by the investigation of Abney and Festing, or of Merritt, affords most satisfactory evidence of the accuracy of Thomsen's results. Let us take, for example, the case of an incandescent lamp, in which 5 watts per candle-power are expended, and in which the ratio

$$\frac{\text{Luminous radiation}}{\text{Total radiation}} = \cdot 05.$$

The energy converted into light in such a lamp is ·25 watt.

Now, 1 gramme calorie = $4{\cdot}2 \times 10^7$ ergs.

$$1 \text{ watt} = 10^7 \text{ ergs} = \frac{1}{4\;2} \text{ gramme-calories per second.}$$

$$\cdot 25 \text{ watt} = \frac{25 \times 60}{4{\cdot}2} \text{ gramme-calories per minute, and the}$$

heat equivalent of the luminous energy is 3·6 gramme-calories per minute.

This value is somewhat smaller than those given by Thomsen in the preceding table, but proper corrections for the diathermancy of the water bath used in his experiments and for the difference in standards of candle-power —the light given by his sperm candle being slightly in excess of the legal standard of the present day—will bring the two into excellent agreement.

The entire energy developed by the chemical reactions occurring in these flames per candle-power of the light produced were, however, about 1,400 calories in the case of candle and oil lamps, and 4,100 calories in the case of gas, so that the gross efficiency would be respectively ·3 per cent. and ·1 per cent. The average ratio of total radiation reaching the thermopile to luminous radiation is about ·2 per cent.; but this ratio cannot be considered in the same light as that obtained in the case of the incandescent lamp, since a gas or oil flame is in reality a column of heated vapour containing particles of unconsumed carbon, which reaches far above the luminous region, sending out dark

* Julius Maier: "Arc and Glow Lamps," p. 52.

Digitized by Google

rays from its upper and cooler portions, which do not reach the face of the thermopile at all. The relation which the total radiation of this heated column bears to the heat dissipated by convection cannot be determined, and the determination of total radiation from the light-giving portions alone is of little value. It is only in the matter of gross efficiency, therefore, that we can institute a comparison between electric lamps and the older methods of illumination, and the gross efficiency of the former depends upon the efficiency of production of electric current. Under conditions, such that 10 per cent. of the total energy of the fuel consumed is converted into electricity—conditions which are, I believe, rarely attained by our present methods—the gross efficiency of an incandescent lamp, of which the net efficiency, determined by the methods which I have already described, is 5 per cent., would be ·5 per cent.; a value which is five times greater than that of a lamp burning the kind of gas used by Thomsen, and which stands in the ratio 5 : 3 (or, probably, rather more than that) to the gross efficiency of an oil flame. These flames must, of necessity, vary very widely with the quality of the fuel consumed, and with the condition under which combustion is maintained.

If we apply a similar method of computation to the values given by Mr. Preece in his recent address at the Bath meeting of the British Association for the Advancement of Science*, assuming that the conditions under which each illuminant is consumed are such that the temperature of the incandescent carbon equals that which is maintained in the filament of an incandescent lamp at 5 watts per candle with a net efficiency, as before, of 5 per cent., a set of conditions which can be attained in practice only in the most perfectly constructed oil and gas lamps, and which are fulfilled in many of the best of our incandescent lamps of to-day, we obtain the following results.

TABLE VI.

Gross efficiency of various illuminants deduced from the values given by Preece. The heat equivalent of the candle is assumed to be 3·6 gramme-calories per minute.

Illuminant.	Watts per candle. (Preece.)	Gramme-calories per min. per candle.	Luminous radiation. / Total radiation = gross efficiency.
Tallow	124	1770·	·0C203
Wax........	94	1340·	00268
Sperm	86	1230·	·00293
Mineral oil	80	1143·	·00315
Vegetable oil	57	815·	·00442
Coal gas	68	971·	·00317
Cannel gas	48	685·	·00521

In considering these values it should be borne in mind that coal-gas is a fuel which has been obtained by the previous expenditure of considerable energy. Were we to take as our basis the consumption of coal necessary to the production of a candle-power of light, instead of the heat of the combustion within the gas flame itself, the values for the efficiency of coal-gas as an illuminant would be very considerably reduced.

We have already seen that there are excellent experimental grounds for the statement that the gross efficiency of the incandescent lamp is about ·005, and that of the arc lamp about ·01, under the assumption of the waste of 90 per cent. of the total energy of the fuel in the various processes leading to the production of the current, and that the latter figures, small as they are, are considerably in excess of the gross efficiency of candles, oil, or gas. We are in possession, moreover, of the means of expressing exactly the degree of superiority which the electric light possesses over those illuminants in the important matter of the heating effect upon the surrounding atmosphere. Gas and oil flames deliver in the neighbourhood of 1,000 gramme-calories of heat per minute to the room for each candle-power, of 3·6 gramme-calories of luminous radiation. An incandescent lamp of 5 per cent. net efficiency delivers only 72 gramme-calories per candle-power.

* Preece. Address before Section A. meeting of the B.A., at Bath, 1888. *Nature*, vol. 38, p. 496.

The net efficiency of the incandescent lamp may be raised somewhat by increasing the temperature of the carbon filament, and, indeed, it has already been somewhat raised by the introduction of the new "three watt" lamps. These lamps have been excluded from this discussion because we have as yet no complete data with reference to them, and because it seemed desirable, aside from that, to institute comparisons between sources of illumination in which the degree of incandescence was the same, and for all of which, consequently, candle-power had the same meaning.

When we raise the temperature of our source of light, however, we introduce changes of which the methods thus far considered take no cognisance.

In increasing the degree of incandescence, the ratio of luminous energy to total energy of radiation is slowly increased, and at the same time the relative brightness of the various rays which constitute the visible spectrum changes. In a word, the quality of the light changes, and we are confronted by important variations which cannot be expressed in candle-power.

The investigation of these changes in composition, upon which colour depends, involves the study of the visible spectrum of the source of light, and the comparison of its intensity, wave-length for wave-length, with the spectrum of some properly-chosen standard. The instrument necessary to this work is the spectro-photometer, by means of which the spectra of the two lights to be compared are brought together in the field of view, one above another, like wave-lengths everywhere in the same vertical line. The measurements consist in bringing the two spectra to the same intensity in each of the regions selected for observation successively, and in determining the amount by which it is necessary in each case to reduce the intensity of the brighter. A variety of devices have been made use of for varying the brightness of the spectra, and the standards of comparison adopted by different observers have included the candle, the petroleum flame, the gas flame, and the incandescent lamp, maintained at a constant voltage. Thus W. H. Pickering* obtained the necessary range of intensities by placing the lamp under inspection upon a sliding carriage, and varying its distance from the slit of the spectroscope. His standard of comparison was a gas flame. H. C. Vogel† used as his standard a petroleum flame. Crova,‡ who brought the intensities of the two spectra to equality by means of a polarising device, adopted the moderator lamp as a standard. Otto Schuman, in his study of the incandescent lamp, made use of a "benzine" candle. The intervention of a revolving disc with open and closed sectors and of wedges of smoked glass have also been applied to the regulation of the intensity, and the method of varying the width of the slit itself, a device due to Vierordt, has been found to give good results where the range of intensities was inconsiderable.

The methods of presenting the results of this class of measurement have differed as widely as the methods of observation and the choice of standards; but it is possible, wherever the data are properly given and the character of the standard is known, to reduce them all to a common basis of comparison. When thus reduced, these measurements are found to agree in all essential particulars, and they afford us very definite knowledge of the character of the light emitted by the sources of illumination to which the spectro-photometer has been applied.

Fig. 7 shows the form of the spectro-photometer recently used by W. S. Franklin and myself in an extended series of observations upon artificial sources of illumination, and in the comparison of their spectra with that of daylight.

To the slit of a one-prism spectroscope are attached a set of total reflection prisms, *r*, by means of which rays may be introduced into the upper and lower halves of the slit, these rays coming respectively from sources of illumination placed to the right and left hand in a line at right angles to the axis of the collimator tube. The standard of illumination, which is an incandescent lamp, S, maintained at 16 candles, is placed at the observer's right hand.

Its rays having been rendered parallel by means of a condensing lense, *l*, pass through a pair of Nicol's prisms, N

* W. H. Pickering, *Proceedings* of the American Academy of Arts and Sciences, vol. 15, 1880. † H. C. Vogel, *Berliner Monatsberichte*, 1880, p. 801. ‡ A. Crova, *Comptes Rendus*, 87, 1878, p. 322.

Digitized by Google

and N′, the first of which is free to revolve, and enters the upper half of the slit. The intensity of the spectrum of this lamp can be reduced at will by the rotation of the first Nicol, and its brightness is calculated from the angle between the flames of polarisation of the two Nicols. To the left of the slit is mounted a block of magnesium carbonate, its face vertical, and forming an angle of 45deg., with the axis of collimation of the spectroscope. The rays of the source of light to be investigated, S′, which is placed at a convenient distance, fall upon the magnesium carbonate, and is such of the diffusely reflected rays from the latter as reach the total reflection prisms, and thus enter the lower half of the slit, which form the second spectrum.

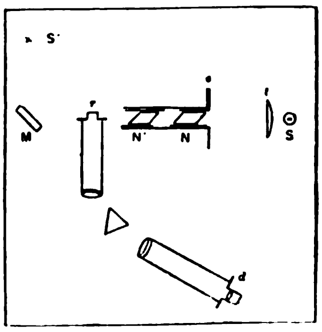

FIG. 7.

The object gained by the interposition of this white surface is an important one. All artificial light, except that from an incandescent lamp, emanates from glowing materials varying greatly in temperature, and the spectrum obtained directly from the source is always that due to some particular portion of the luminous body under investigation to the exclusion of the remainder, and differs more or less in character from that of the source taken as a whole.

(To be continued.)

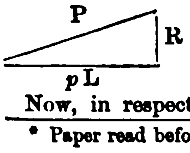
ON LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS.*

BY DR. OLIVER LODGE, F.R.S., MEMBER.

(Continued from page 358.

Material of the Lightning Conductor.

25. A few words may suffice to explain the nature of the impedance which alternating currents meet with in passing through a conductor, and of the reason why iron is as good as, or even better than, copper for the purpose of conveying currents alternating with extreme rapidity. A rising current has to magnetise the space all around it, and the production of this magnetisation delays and impedes the rise of the current to its maximum value. A falling current permits the magnetisation of the space all round it to decay, and the dying out of this magnetisation delays and impedes the fall of the current to its minimum. The more rapidly the current changes, the more powerfully felt is the influence of the accompanying magnetisations and demagnetisations. Now, the total magnetisation produced by a current—its total number of lines of force, or its total "magnetic *induction*," as it is often called—is proportional to the current strength: equal to it multiplied by some constant, which we may call L, and write $I = L\,C$, where I is the total induction produced by the current C. L is a coefficient characteristic of the circuit, its value being defined by this equation, and is called the coefficient of induction excited by the current's own self, or the coefficient of self-induction. If the current goes through $p/2\pi$ complete alternations in a second, it can be shown that the impedance it meets with, due to the reversals and re-reversals of its own magnetic field, is p L. This is not the whole obstruction it meets with, but it is the only part which does not dissipate energy and cause its vibrations to decay. It may be called the *inertia* part of the impedance. The remaining part of the total impedance is resistance, R, the dissipation of energy coefficient, defined by heat per second $= R\,C^2$; and the total is the resultant of these two as if they were not right angles to each other. So that calling P the total impedance,



$$P^2 = (p\,L)^2 + R^2.$$

Now, in respect of the R term, iron is much worse than copper, not only seven times worse, 100 times worse; but then for very rapid alternations the R term is altogether insignificant compared with the p L term.

26. In respect of the p L term does the material of the conductor matter? Well, in so far as the magnetisation spoken of is that of the space surrounding the conductor, of course, the substance of the conductor itself matters nothing. But in so far as the conductor itself gets magnetised, the material of which it is made does matter. Now, a linear current magnetises at right angles to itself everything surrounding it—most intensely the things close to it. A hollow cylindrical current magnetises everything outside itself, but nothing inside. If the current were to distribute itself uniformly through the section of the wire, the outside of the wire would get magnetised in concentric cylinders; but if the current were to confine itself to the outer surface, and flow as a hollow cylinder, it would escape the necessity of magnetising the wire at all. In cases where the p L term is much more important than the R term this is precisely what it does therefore. It always flows so as to meet with the least possible total obstruction; and it finds less total obstruction by cramping itself into the periphery of the wire than it would find if it utilised the whole section. The cramping into the periphery increases R, but it decreases p L; and on the whole with rapidly alternating currents this is an advantage, and gives a smaller value to P. Slowly changing currents think most about R, and use the biggest cross-section they can find. Rapidly changing currents think most about p L, and avoid having to magnetise more than they need. Especially must they avoid having to magnetise the conductor if it consists of iron: hence in that case they cramp themselves tremendously into its outer skin, and thereby avoid having to overcome much more total impedance than they meet with in the case of copper; but though they thus keep down impedance, they increase their dissipation of energy term, and get their oscillations damped out far more quickly than when they only have to pass through copper. The violence of the flash, therefore, subsides more quickly in an iron than it does in a copper conductor; and so I find it experimentally. Nothing here said is in the least hypothetical. It is all absolutely clear and certain, and has been abundantly verified. I will not go into the history of the subject. It is well known.

27. Let it be clearly understood, once for all, that in comparing copper and iron conductors I never mean comparing them as of unequal thickness—*i.e.*, of equal conductivity. Such a comparison is ridiculous in the present state of knowledge. They are to be compared when of the same thickness; and under those circumstances I assert iron to be a trifle better, certainly not a whit worse, than copper, irrespective of all its other manifest advantages—cheapness, fusing-point, etc., etc. Want of flexibility is sometimes urged against iron, but stout telegraph wire is flexible enough; and, until experience decides to the contrary, I feel sure it is thick enough for lightning-conductors. The one and only thing on which anything can be said against iron is on the subject of its durability, and this being a chemical question I offer no positive opinion; at the same time I am absolutely certain that any slight disadvantage in that respect is a hundredfold compensated in most localities by its other superlative advantages.

Current and Potentials during Discharge.

28. In cases where a conductor is pretty thick—say, anything like a quarter inch diameter, or even a tenth, and of any moderate length, such as 100 yards or less (not many miles), the two terms of impedance are so unequal that is for many purposes needless to think about R at all, the impedance is practically p L simply; and this, as I have shown in *Phil. Mag.*, August, 1887, is under any given circumstances half the critical *resistance* which determines whether the discharge shall be oscillatory or not under the same circumstances. The total impedance is commonly to be reckoned in hundreds or even thousands of ohms.

29. The strength of current passing in the alternations can be estimated by considering that the whole quantity stored up in the discharged body has to be transmitted in a quarter of one oscillation period—say, for instance, in the millionth of a second. If the quantity discharged were one coulomb, this would mean a current of a million amperes. In any case the current must be hundreds or thousands of amperes.

30. The difference of potential needed to drive so strong a current through so great an obstruction is enormous, being equal to the product P C, and may be reckoned in millions or hundreds of millions of volts; hence it is that lightning-conductors afford an easy path for lightning, but that it tends to spit off in all directions, even to what would seem, and, indeed, are, very inferior conductors. It will spit off from a well-earthed stout copper rod to bits of wood, and to perfectly insulated bodies.

Effects in the Neighbourhood of a Discharge.

31. Putting together the enormous electrostatic potentials existing at the different points of a conductor conveying a discharge, and the violent oscillation to which so strong a current is subject, we perceive how great must be both the electrostatic and the electromagnetic induction in all space anywhere near it

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

These disturbances, thus rendered certain and accounted for, can easily be experienced experimentally. I proceed to relate a few experiments out of a multitude which I have made.

32. I took a considerable length of highest conductivity, No. 0 electrolytic copper wire, kindly lent me by Messrs. Thomas Bolton and Sons, and arranging one end so as to be accessible to Leyden jars, etc., carried the wire up to a high gallery and then down to earth. Earth was made in several ways on different occasions, water-pipes, gaspipes, hot-water-pipes which ramified the whole building, outside gas mains, bars buried in ground; but the most effective and indeed perfect return circuit could be had when wanted by connecting the end metallically with the outside coat of the jar, without any earth contact at all. When this direct contact was not made, the outer coat of jar had of course to be connected to earth also, in order to complete the circuit. Very often they were both connected to each other and to earth as well. It makes no essential difference; whatever may be considered the most satisfactory method, that may be adopted, and the phenomena will go on just as well. They may be briefly summarised as follows:

(1) If the conductor pass within an inch or two of any uninsulated piece of metal, it gives off a violent side flash to it.*

(2) If the far end of the conductor is neither earthed nor connected to jar, but is left insulated in air, side-flashing from it occurs a trifle more easily, but not very markedly so.

If the conductor pass within, say, ½in. of an insulated conductor, it gives off a side flash to it. The strength of the flash depends on the capacity of the insulated conductor, being considerable if it be large; but some side spark occurs to an absurdly small body perfectly insulated—*e.g.*, such a thing as a coin on a stick of sealing-wax—and this when the conductor is absolutely well earthed at its far end.

(3). Sparks can be obtained from everything, even quite uninsulated things, connected to the conductor. For instance, if it be connected to the gaspipes, small sparks will fly to the finger or to an insulated body from all the gas-brackets about, and these sparks are sufficient to ignite gas.

(4). Sparks can be obtained between the ends of any long curved conductor, be it insulated or uninsulated, if they are brought close enough together to form a nearly closed circuit.

(5). Sparks can be obtained from or between insulated bodies in the neighbourhood of the conductor, and not connected to it at all, every time a flash occurs. For instance, a large piece of wire gauze connected to nothing gave off sparks to a gas-bracket and ignited the gas. Moreover, one piece of wire gauze sparked small sparks into another, neither connected with anything.

In illustration of this, some gilt key pattern high up on the wall of the hall, 25, Great George-street, was seen to be sparking while Leyden jar discharges were going on through a wire lying on the floor. They were not so bright as the sparkings at the Royal Institute wall paper, but the gilding was further from my wire, and I believe is quite far from any wire. As illustrating the motive current produced in conductors during the act of reflecting electromagnetic waves, they were therefore still more satisfactory.

(6). Sparks can be obtained from quite uninsulated bodies, even when not connected with the conductor—*e.g.*, from hot-water pipes, from gaspipes, from water-pipes, from strips of brass let into the table, from gas-brackets in other rooms, from a wire lying on the floor of a distant corridor; and, in fact, all over the building with few exceptions. The sparks can be taken by a penknife held in the hand; sometimes they can be taken to the knuckle or finger-tip even when pressed against them.

(7). Sparks can be got to pass between two totally uninsulated things, neither of which have any connection with the lightning-conductor. For instance, let the conductor be thoroughly earthed in some outdoor and distant manner, and under favourable circumstances a bright short spark can be seen passing at every discharge between a gas-tap and a water-tap of my lecture-table which happen to approach each other closely. Let the gas escape near these sparks and it ignites.

(8). Sparks can be got between two thinly-insulated electric-light wires if they lie close enough together, and if a storage battery be connected to them an arc will be started, destroying the insulation and burning the wires.

(9). If at any distant place, or out of doors in daytime, the sparks are too feeble to be seen, disturbances can still be easily detected by means of a telephone; connecting one terminal to the thing—say, the roof, a shed, or a wire fence—and holding the other end in one hand. Or, of course, by connecting the two terminals to two different things, or to different parts of one thing.

(10). Arrange Abel's fuses between gas and water pipes, between pieces of wire gauze and gaspipe, between hot-water pipe and a bit of sheet metal, between the lightning-conductor and a 6in. metal sphere on long glass stem, between two large insulated bodies, between the gas-bracket of another room and an empty Leyden jar; in short, in almost any place, likely or unlikely. Then take a few strong discharges through the thick copper rod with end well earthed, and the fuses will pop off, some at one discharge, some at another. Very visible sparks can sometimes be seen passing into the fuses, if they be not closely connected, without exploding them. A certain energy of spark is necessary to ignite the composition: much more than is sufficient to excite the retina.

* This easy and striking experiment I stupidly omitted to show at the meeting.

Lightning Protectors.

33. Now let me say a word about the possibility of protecting telegraph and other instruments from damage by lightning currents which may have entered the aerial lines. There is, indeed, no guarantee that burying wires beneath a pavement, or even beneath water, will effectually secure them from lightning disturbance, as I have now fully illustrated, but certainly overhead wires are more exposed. The ordinary and well-known form of lightning protecting arrangement is to attach a pair of plates, or a double set of points, or a pair of points in a vacuum, or some other small air space, as a shunt to the instrument or coil of wire to be protected. Here are arrangements of the kind. Now it is perfectly easy to see that the protection such things afford is of the most utterly imperfect kind. Take a coil of tangled silk-covered wire, or any other coil that you do not mind damaging, and attach it as a shunt to one of these protectors. On discharging a jar through it, the insulation of the coil is pierced in heaps of places; or one may use a short fine wire, and see it deflagrated by the branch discharge.

34. It may be said that my air space is too wide. Very well, then, abolish it altogether. Bring the plates of your protector into direct metallic contact. By so doing, the coil is, indeed, shunted out of the circuit, and if it were a telegraph instrument no signal could be given, for no appreciable fraction of the current takes that route; but with a Leyden-jar flash it is otherwise. Although the plates of the protector are in contact, soldered together if one pleases, and led up to by stout wire or rod, a branch flash still breaks through the insulation of our wire tangle, or deflagrates our little bit of thin wire.

35. It will be said the joints are bad. Well, then, do without joints; take a stout rod of electrolytic copper bent in an arc, say, 2ft. long, and, bridging it across with the wire tangle, discharge a jar round it. Still a portion takes the thin wire, even though it offer a path yards in length. Take a straight bar of copper an inch thick, and arrange an invisibly fine Wollaston wire of greater length as a tapping circuit. Some of the discharge shall leave the bar, and spark across a minute air gap at each end, in order to make use of the hair-like platinum wire. Go further still than this. Connect a coil of thin-covered wire *by one end only* to a wire conveying a discharge, standing the reel upon a block of paraffin or other good insulator, and connect the other end to any little thing of any capacity at all—say a bullet lying on the block of paraffin: you can see sparkings through the insulation of the wire on the reel at every discharge. These experiments render manifest the hopelessness of any simple shunt arrangement as a lightning protector.

36. The easiest mode of exhibiting the essentials of these experiments, one that can be tried by anyone possessing a Leyden jar, a pair of discharging tongs, and a yard or two of fine silk-covered wire, is to hang a tangle of the wire loosely on to the tongs, not necessarily making any sort of good contact, and then use them to discharge a jar in the very ordinary way. Some of the flash will take the thin wire, and will spark through the insulation at a number of points.

37. It may be very well objected to me that it is pretty useless if I only point out the imperfection of present methods, and offer no suggestion as to a proper lightning protector. Well, this struck me, too, and the result is that I have devised and made what I think I may call an absolutely perfect protector—one into which great flashes may be sent, and yet the galvanometer or instrument intended to be protected shall not wink nor shall the slightest palpable or visible disturbance be discernible, notwithstanding that complete metallic contact is maintained all the time, and not a trace of the signalling or useful current wasted. The thing seems so good that I am making it the subject of a patent, and you will, therefore, pardon me for saying no more about it just yet.

38. The next part of this paper is largely controversial. I do not take much pleasure in this portion, and wish it were unnecessary. But it is a purely impersonal controversy; and so long as the old-fashioned views are in existence, one way of arriving at the truth is to try and thrash them out of existence. If there is any real vitality in them, the attack will fail. It will be well believed that I have no feeling of hostility to the Lightning-Rod Conference, when my best scientific friend, Prof. Carey Foster, was one of its members. Had I been one myself, I no doubt should at that time have signed the very documents which now, in a few places, I criticise. Had I, indeed, so signed, I would abuse what I now see to be its erroneous portions with still more vigour than I now permit myself to employ.

Summary of Points of Difference and Controversy.

39. It may be convenient here to summarise a few of the points wherein the doctrines which I advocate differ from the

Digitized by Google

views held by the older electricians. And the summary will give me an opportunity of emphasising the incorrectness of the older views in many instances. I quote a few statements prefixed by capital letters from an abstract I made for the *Electrician* after the Bath meeting of the British Association.

A. Rods, as at present constructed, though frequently successful, may and do sometimes fail, even though their earth is thoroughly good, the reason being that they offer to a flash a much greater obstruction—a much worse path—than is usually supposed: an obstruction to be reckoned in hundreds or thousands of ohms, even for a very thick copper rod. N.B.—This is not resistance proper, but impedance.

I may be permitted here to repudiate the doctrine which has several times been attributed to me since the Bath meeting, that it is safest to be without lightning-conductors altogether. The long experience of persons learned in this art is by no means to be despised, and until an agreement as to improvements has been arrived at, the safest plan for ordinary persons is to adhere to existing practice. Nevertheless, that conductors sometimes fail, is as certain as that they often succeed. My statement is that customary arrangements are not perfect, and are susceptible of improvement. The statement of the Lightning-Rod Conference is that "there is no authentic case on record where a properly constructed conductor failed to do its duty." Mr. Preece calls the statement "most decisive." It is certainly decided, and in the light of other matter contained in the same red covers I assert it to be in its natural and intended signification decidedly false. The only signification which makes it true makes it also senseless; as if one should record the statement that white things are white. In my Society of Arts lectures, I said nothing against the report of the Lightning Rod Conference, because the work done by that body, in collecting information, abstracting papers, and recording instances, was obviously very valuable, and much of the report itself is correct; while as for the occasional rash statements in that document I imagined the signatories would wish them to sink into oblivion in silence. But Mr. Preece has revivified them, and conspicuously made himself afresh responsible for them;* accordingly I now extract one or two more sufficiently dogmatic and unfortunate statements from the same source.

"A man may with perfect impunity clasp a copper rod an inch in diameter, the bottom of which is well connected with moist earth, while the top of it receives a violent flash of lightning."

"If all these conditions be fulfilled; if the point be high enough to be the most salient feature of the building, no matter from what direction the storm may come, be of ample dimensions, and in thoroughly perfect electrical connection with the earth, the edifice, with all it contains, will be safe, and the conductor might even be surrounded by gunpowder in the heaviest storm without risk or danger."

To adhere to such views as these now, with tenacity sufficient to cause them to be promulgated as authoritative scientific statements would be, in my opinion, little less than criminal.

"All accidents may be said to be due to a neglect of these simple elementary principles." Certainly this "may be said," because it already has been said over and over again; but it cannot be said with truth.

Whenever an accident happens, a believer in the modern exponents of the Lightning Rod Conference who could not point out a flaw, or a bad joint, or a bad earth, or a possible flaw, or a possible bad joint, or a possible bad earth, would feel himself disgraced as a practical man. An instance occurred in quite a recent number of *Nature*. The writer of "Electrical Notes" records that a number of fish had been killed in a pond into which the earth end of a conductor had been led, and concludes with the ejaculation, "When will people learn to make proper earth connections?" I select this instance as typical of the extraordinarily contradictory advice often bestowed on that long-suffering body the British public. Before an accident, the pond would be pointed out as an excellent earth, as indeed it most likely was. After the slaughter of the fish, the erector of conductor is impersonally ridiculed for having utilised it. So with any struck building. After an accident defects must be forthcoming, because else there would be "an authentic case on record where a properly constructed conductor failed to do its duty," which *ex hypothesi* is absurd and impossible; therefore it was not constructed in accordance with the directions of the Lightning Rod Conference, therefore it was defective. *Q.E.D.*

B. When a Leyden jar is charged it corresponds to a bent spring, and its discharge corresponds to the release of the spring. Its discharge current alternates, therefore, in the same way and for much the same reason as a twitched reed or tuning-fork vibrates. The vibrations decay in either case because of frictional heat production, and because of the emission of waves into the surrounding medium. A single spark of a Leyden jar, examined in an exceedingly fast revolving mirror, is visibly drawn out into a close succession of oppositely-directed discharges, although its whole duration is so excessively minute. It is very likely that this statement will now no longer be denied. So I pass to the next.

* Saying at Bath, as a prelude to a quotation from the report, "The report itself is most decisive and most important; there is a true ring about it—the ring of men who knew what they had done, and what they were writing about."

C. A lightning flash is a spark between cloud and earth, which are two oppositely electrified flat surfaces, and the flash corresponds, therefore, to the internal sparking between the two plates of a great air condenser. All the conditions which apply to a Leyden jar under these circumstances are liable to be true for lightning. Sometimes the resistance met with, either in the cloud itself or in the discharger, may be so great that the spark ceases to be oscillatory, and degenerates into a fizz or rapid leak; but there can be no guarantee that it shall always take this easily manageable form; and it is necessary in erecting protectors to be prepared for the worst and most dangerous form of sudden discharge. The apparent duration of a lightning flash is due to its frequently multiple character, and indicates successive discharges, not one long-drawn-out one. Nothing that lightning has been found to do disproves its oscillatory character, because Leyden jar discharges, which are certainly oscillatory, can do precisely the same. This was in answer to Mr. Preece's contention that lightning could not be oscillatory, because it magnetised steel bars and deflected ships' compasses. The next is an antidote to the continually made statement that the one thing needful for an efficient lightning-conductor is conductivity.

D. Although some conductivity is necessary for a lightning-conductor, its amount is of far less consequence than might be expected. The obstruction met with by an alternating or rapidly varying discharge depends much more on electromagnetic inertia or self-induction than upon common resistance. So much obstruction is due to this inertia, that a trifle more or less of frictional resistance, in addition, matters practically not at all. It is very desirable to have a good and deep earth in order to protect foundations and gas and water mains from damage, and in order to keep total impedance as low as possible. I find it sometimes thought that I have argued against the need of a good earth. This is not so. I have argued against the exclusive and exaggerated attention that has been paid to this need.

In opposition to the following statements, *e*, *f*, *g*, *h*, *i*, the substance of which may be considered as hitherto orthodox, I make the statements subsequent, labelled, E, F, G, H, I:

e. No danger is to be feared from a lightning-conductor if only it be well earthed, and be sufficiently massive not to be melted by a discharge. All masses of metal should be connected to it, that they may be electrically drained to earth.

f. The shape of the sectional area of a conductor is quite immaterial; its carrying power has nothing to do with extent of surface; nothing matters in the rod itself but sectional area or weight per foot run, and conductivity.

g. Points, if sharp, should constitute so great a protection that violent flashes to them ought never to occur.

h. Lightning-conductors, if frequently tested for continuity and low resistance by ordinary galvanic currents, are bound to carry off any charge likely to strike them, and are absolutely to be depended upon. The easiest path protects all other possible paths.

i. A certain space contiguous to a lightning-rod is completely protected by it, so that if the rod be raised high enough a building in this protected region is perfectly safe.

These statements I say are erroneous. The following I believe to be correct:

E. The obstruction offered by a lightning-rod to a discharge being so great, and the current passing through it at the instant of a flash being enormous, a very high difference of potential exists between every point of the conductor and the earth, however well the two are connected; hence, the neighbourhood of a lightning-conductor is always dangerous during a storm, and great circumspection must be exercised as to what metallic conductors are wittingly or unwittingly brought near or into contact with it. When a building is struck, the oscillations and surgings all through its neighbourhood are so violent that every piece of metal is liable to give off sparks, and gas may be lighted even in neighbouring houses. If one end of a rain-water gutter is attached to a struck lightning-conductor, the other end is almost certain to spit off a long spark, unless it also is metallically connected. Electric charges splash about in a struck mass of metal, as does the sea during an earthquake or when a mountain top drops into it.* Even a small spark near combustible substances is to be dreaded.

F. The electrical disturbance is conveyed to a conductor through the ether or space surrounding it; expressed more simply, lightning currents make use of the periphery of a conductor only, and so the more surface it exposes the better. Better than a single rod or tape is a number of separate lengths of wire, each thick enough not to be easily melted, and well separated so as not to interfere with each other by mutual induction. The liability of rods to be melted by a flash can be easily over-estimated. A rod usually fails by reason of its

* *See* the Report of the Krakatoa Committee.

Digitized by Google

inertia-like obstruction, and consequent inability to carry off the charge without spittings and side flashes; it very seldom fails by reason of being melted. In cases where a thin wire has got melted, the energy has been largely dissipated in the effort, and it has acted as an efficient protector; though, of course, for that time only. Large sectional area offers very little advantage over moderately small sectional area, such as No. 5 B.W.G.

G. Points, if numerous enough, serve a very useful purpose in neutralising the charge of a thunder cloud hovering over them, and thus often prevent a flash; but there are occasions, easily imitated in the laboratory, when they are of no avail: for instance, when one upper cloud sparks into a lower one, which then suddenly overflows to earth. In the case of these sudden rushes, there is no time for a path to be prepared by induction, no time for points to exert any protective influence, and points then get struck by a violent flash just as if they were knobs. Discharges of this kind are the only ones likely to occur during a violent shower, because all leisurely effects would be neutralised by the rain drops better than by an infinitude of points.

H. The path chosen by a galvanic current is no secure indication of the course which will be taken by a lightning flash. The course of a trickle down a hillside does not determine the path of an avalanche. Lightning will not select the easiest path alone; it can distribute itself among any number of possible paths, and can make paths for itself. Ordinary testing of conductors is therefore no guarantee of safety, and may be misleading. At the same time it is quite right to have some system of testing and of inspection, else rust and building alterations may render any protector useless.

I. There is no space near a rod which can be definitely styled an area of protection, for it is possible to receive violent sparks or shocks from the conductor itself; not to speak of the innumerable secondary discharges which, by reason of electro-kinetic momentum and induction, and by reason of electromagnetic waves of the curious recently discovered effect of the ultra-violet light of a spark, are liable to occur as secondary effects in the wake of the main flash.

(To be continued.)

BOARD OF TRADE ENQUIRY.

WEDNESDAY, APRIL 17.

Major Marindin, C.M.G., R.E., on behalf of the Board of Trade, resumed the enquiry at the Westminster Town Hall, for the purpose of hearing, on the part of a number of electric lighting corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

Mr. Henry Blake (chief clerk to the Commissioners of Sewers) was examined by Mr. Russell Griffiths, and gave evidence as to the amount which had been expended on electric lighting in the City from 1878 to 1888 inclusive, the total sum having been £12,519. He had got in his custody the tenders made by the various companies for the electric lighting. In some of those tenders there were certain conditions as to the private lighting of the City. He had seen the streets of the City opened from time to time at various places. There were a great many pipes of various kinds underneath. Supposing two companies were allowed to compete within the area of the City, laying down mains in competition with one another, whether there would be room for them would depend a great deal on the depth they wanted to go to, and whether it was below the footways or the roadways. There would be a great difficulty in going below the gaspipes.

Cross-examined by Mr. Pember, he said that he knew nothing in the Electric Lighting Acts which excepted the City of London from the general operations of the Acts. The Commissioners practically paid small attention to the question of private lighting except that they were desirous of giving the public the benefit of the light under guarded conditions. He did not think that those conditions were in conflict with the Electric Lighting Acts of 1882 and 1888. The Commissioners had always gone on the principle that they had a right to deal with the pavements as should seem best for the good of the public. The power of corporations to purchase electric light companies' interests up at the end of 42 years constituted a material difference in their position from that of a gas company which had got its work for ever. They considered that in all cases they were giving a great boon to contractors by giving a wayleave for private lighting.

Cross-examined by Mr. Lyttleton, he said he did not know that a great many applications had been received by the Metropolitan Company from the City. If the Commissioners were satisfied with the license or the provisional order, he did not know that they would oppose any public lighting company going into the City. There were only two applications for provisional orders which the Commissioners were opposing now. They must be satisfied with the provisional orders before giving their consent.

Mr. Wm. Henry Preece, electrician to the Post Office, was called and examined by Mr. Griffiths. He said that he had advised the Commissioners of Sewers in electric lighting since 1882. He had been consulted since that year, but he had been associated with electric lighting since 1878. The residential number of persons within the City was 261,061, a number greatly increased in the day time. There would be a great many places that would require to be lighted during the day as well as during the night, as every available place that could be used for offices was let. That made the use of artificial light in the City during the day time a greater necessity than it was in other places. It was not only a necessity, but a great value. The estimated number of gas lamps in the City was 622,000 used for ordinary purposes. The ordinary average was 5ft. per hour per gas burner. The number of public gas lamps lighted in the City was 3,136, lighted at a present cost to the Commissioners of £10,530. The time during which light would be required for private purposes would be up to about seven. There were printing works and other places going on all night, so that there would be a great deal of light wanted during the night as well as during the day. The office hours in the City might be fairly taken up to seven, although there were a great many closed at five and six.

Mr. Pember: And some stay later.

Witness: Yes.

By Mr. Griffiths: It was an extremely difficult thing to form anything like an accurate estimate of the number of hours of lighting a place like the City, and the only illustration he could get to draw any conclusion from was the central station of New York, started by the Edison Company in the neighbourhood of Wall-street, somewhat similar to the district of the City, and when he was in America in 1884 he took a great deal of pains to arrive at a fair conclusion as to the average number of hours per lamp per day, and it came out at 2·4 hours per day. That was 876 hours per annum. That lighting was for the City purposes—offices, lighting, restaurants, and places of that kind—a fair average for places like the City for private lighting. The latitude of New York was 41, that of London 52, which would make an hour's difference in the daily average of the length of lighting in London. He doubted very much whether it was fair to draw a comparison between the private lighting of a business quarter like the City and the private lighting of a district like Kensington or Wimbledon. Of course, in a business place such as a bank, for instance, or a club, nearly all the lights were alight at once, but in a private house in the suburbs there would be a number of lamps in bedrooms which would be only used for a very short time—when the occupants were going to bed. One sitting-room might be occupied at one time, and another at another time, so that the average hours of burning a lamp in a private house was no criterion of what it would be in a place of business. He had heard the evidence of Mr. Crompton, who put the apex of the curve of light at seven o'clock, while he thought the principal demand was from five to seven. If a company supplied largely the residential part, and the shops and the theatres in the West End, he thought if they attempted to supply the City at the same time in the four winter months they would overlap very much. The consequence of that would depend very much upon the arrangement of their plant in ratio to the several demands. If they started with too small a plant for the ratio of the demand in the City, he thought their supply would rather diminish. If the electric light were to be supplied by running machinery without any storage, there would be great difficulty in meeting the double demand of the City and West End, unless additional machinery were provided. There was no question that the effect of running machinery light was that it ran very uneconomically. There were 46 miles of streets in the City including courts and alleys, and he estimated that the number of public lamps that would be required would be 500 of what were called 500 watt arc lamps—they varied, of course, very much—also 1,000 glow lamps of 25 to 32 c.p. Taking the estimate that he had given for private lighting at 622,000 gas lamps, he thought they might fairly assume, in competition that must take place between electricity and gas, that they would get a third of that—say, 210,000 glow lamps—in the City, or 70,000 for each of the three districts. The latter would be 10 c.p. lamps. The Post Office, which was partially lighted by electricity, had its own installation and machinery, which were put up under his superintendence. The cost of lighting the Post Office per unit of the Electric Lighting Act was 3½d.—the Board of Trade unit. They used Willans and Robinson's engines, which were not the most economical, and if they were replaced by engines of the present day he thought the price could be reduced to 2½d. per unit. There were in the City a great number of private installations supplying light to institutions. He had considered the scheme proposed by the London Electric Supply Corporation for the transmission of their high-tension current from Deptford to London, and he considered it a gigantic experiment. The grounds on which he formed that opinion generally were these—that he was a decided advocate for the distribution of electricity over extended areas by means of alternating currents and the transformer system, and he considered that the question of concentrating all their eggs in one basket, as the London Electric Supply Corporation had at Deptford, or distributing their central stations over the metropolis as the other companies proposed to do, was simply a commercial question of pounds, shillings, and pence. There had been ample evidence pro and con, and if a balance-sheet were struck between those reasons he thought that it would be found that they balanced each other very fairly; that there was almost as much to be said in favour of one large station down the river as there was in favour of several stations scattered over a district. But his strong objection to the scheme of the London Electric Supply Corporation was not a question of their central station, for he believed that had been perfectly worked out, but it was the connection between London and Deptford by means of their mains. The question did not seem to him to have been at all solved by Mr. Ferranti, and he regarded the proposals, as submitted to that tribunal, as very objectionable indeed. He thought that the form of main proposed by the London Electric Supply Corporation was not in consonance at all with the rest of their scheme, and it was a very weak point, requiring further and more mature consideration. He thought it was quite practicable to have a dynamo driven by 5,000 or 10,000 h.p., and it was perfectly practicable to make steam-engines and dynamos that would

Digitized by Google

convert 10,000 or 20,000 h.p. into the form of energy called electricity, but the difficulty he was now contending for was that of transporting the converted energy from Deptford to London. He anticipated difficulties of insulation of joints and difficulties of disturbance to contiguous telephones and telegraphs. He had not seen any motor to which they could supply all the energy produced by the alternating system. There were two or three spoken of as existing, but they had not been produced yet. One was called the Telsa motor, invented in America, but it was not in the market. There were motors in the market for using the energy supplied by the direct system. He thought there would be a large demand within the City for motive power supplied by electricity, which would certainly, during the day, be a remunerative source of income to any company. He personally considered the sub-division of the City into three districts. The main reason that controlled the Commissioners of Sewers in deciding upon that, he believed—and it certainly guided him in recommending the division of the City into that number of districts—was that they could give in the first place the public the benefit of competition, while the authorities themselves would be relieved from the very greatest inconvenience of competition—that was by having their streets cut up by rival companies. The main streets were at present choked up with pipes. The Post Office, for example, down Cheapside had 15 to 20 pipes of their own, and he did not think it would be possible at the present moment to lay a six inch main down that thoroughfare. There was one objection to competition, and it was this, that if they had two companies through one district they would require double mains, double plant, and double capital. If the favours of the public were equally bestowed, those companies only got half the revenue each, and the result was that sooner or later such competition led to amalgamation, which generally led to enhanced prices to the public, who had to pay in the end. They therefore felt it would be much better if competition could be prevented in any of those districts. On the other hand, there was no doubt that competition secured splendid services—or rather the fear of competition. As regarded danger to persons from the mains from Deptford, he thought that no more effective mode could be suggested than that by Mr. Ferranti. If the outside conductors were buried in earth, or in contact with it, he did not think that any person would be liable under ordinary circumstances to get a shock, but the difficulty would be that the telegraphs would suffer. If the main between Deptford and London formed a curve, there would be conduction through the earth—the equality between the two currents upon which the security of telegraphs depend would be broken. His opinion was that with the outside to earth all the telephones in London would be affected with a pressure of 10,000 volts in main as designed by Mr. Ferranti. There was not a single telephone in London that would not be disturbed—so much, perhaps, as to prevent speech—by the alternating currents from Deptford. Telegraphic and telephonic wires all centred in the City, and were principally above ground, some being below. The maximum price proposed by the electric lighting orders was 8d., he believed. He anticipated in the progress of electrical knowledge and science that electrical energy might be produced at a cheaper rate than now. They were in a regular wave of progress, tending to economy in production.

Cross-examined by Mr. Pember: The disturbance set up in the telephone and telegraph wires to which he referred depended on there being a curve between London and Deptford; but if they could get an absolutely straight line that electrostatic induction would not be set up. Earth conduction would be effected. There would, however, be a considerable disturbance even if they had a straight line from London to Deptford. He had no doubt whatever that a cable carrying the London Electric Supply Corporation's current from Deptford to London could be made which would get rid of the Post Office objection. When that was done, any objection he had seen to the company's scheme vanished, and ensured safety to the public. He had not the slightest doubt that there would not be any difficulty in finding a proper motor which could be adapted to the alternating system. Leaving out of the question that the Board of Trade undertook safety to life, and the Post Office safety to telegraphs, he saw no other objection to the system. He did not think that in the case of electric lighting under the provisional orders competition could lead to amalgamation. If he were acting as an engineer to an electrical company like the London Electric Supply Corporation, he would advise them to tender on the basis of being ousted in 21 years, having all their undertaking bought up, provided it was by agreement with arbitration.

Cross-examined by Mr. Lyttleton, he said that there would be a difficulty in supplying the City and the West End at the same time. He did not know that a canvass had been made of the City showing a demand for not more than 60,000 lights. He spoke as the technical adviser of the City, and approved of the specification which h d been drawn up, and upon which tenders were asked. He thought it would be impossible to lay a main in Cheapside. The conditions had very largely altered since Mr. Siemens had lighted parts of the City. The Post Office alone had quite doubled the number of their pipes there.

Re-examined by Mr. Griffiths, who asked whether the 3½d. per unit of production included working expenses, the **Witness** replied that it did.

Major Marindin: I understood that nothing is included for capital charges, rent charges, or distribution.

Mr. Griffiths: No.

The **Witness**: That is so, and no depreciation.

By Mr. Griffiths: He knew that experiments were being made as to the insulation of those rigid mains referred to with regard to the outer sheathing. The result was merely a question of weeks. They had not contemplated in those experiments the reduction of voltage. They were dealing with a main carrying 10,000 volts. He thought, as an electrician, that some form of insulation would be found for such a main, and with Mr. Ferranti's precautions the dangers to the individual would be reduced to a minimum.

Examined by Major Cardew, he said that it was the case that, assuming the proposed main to be earthed at Deptford, and also to be earthed at the distant end, the inequality in the two conductors thus produced would cause an interference with telephones from current inductions. In addition to that there would be a certain interference with telephones from electrostatic induction, which was a different thing. But as long as the insulation was perfect, and if the earth could be kept to the generating point, there was no reason why there should be any current inductive effect.

Mr. Robert Hammond, managing director of the House-to-House Electric Lighting was Company, called and examined by Mr. Shiress Will: He said he had been engaged in the business for some years. Their nominal capital was £350,000, of which £41,000 had been subscribed. He anticipated no difficulty in getting the whole of their capital subscribed if the powers of the provisional order were granted. His company was not bound to any system. That actually in use was the high-tension alternating-current converter system, of which he had had six or seven years' experience. He was distinctly in favour of districting, and had been from the very beginning of the industry. He thought that the effect of competition between two or three companies in one area would be, although at first favourable to the consumer, at last disastrous, as the company left in possession of an area was able to obtain capital much more readily. There was much more inducement to invest capital if a district belonged to one company, and he thought that sufficient guarantees could be given by that company that it would not charge an excessive price. It would be to the interest of the company to do their best to serve the consumer. The fixing of a standard price would be to the interest of both the company and the consumer. He thought they could cover a district much more quickly with the converter than with the low-tension system by reason of the cheaper mains. In regard to the standard price, he might add that it was to be a price based upon a dividend. In their order they had inserted the dividend of 10 per cent., but the standard price should be based upon the payment of a dividend of 10 per cent., and they would have the power of increasing that dividend on reducing the price as the Gas Works Clauses Act provided. By placing works some distance off in the centre of the manufacturing district, it was very often possible to obtain some advantages in production, but he considered that it was absolutely destroyed by the cost of distribution.

Cross-examined by Mr. Wallace, he said that the cost of production of electricity for Board of Trade purposes at Brighton amounted to 6½d. a unit last year. It was not only the cost of the converter system, but of the Brush system. Last year was the year that they converted from one to the other. The works at Brighton were very small, and it was a marvellous thing to be able to produce electricity for that price when they were running only some 400 h.p. They proposed to charge on a sliding scale, depending upon the number of hours a man use. his light. They would allow the consumer to fix his own minimum of hours.

Mr. Wm. Lowrie, called and examined by Mr. Shiress Will, said he was engineer to the House-to-House Electric Light Company, as well as to Messrs. Hammond and Co. The voltage at which he sent out the electricity at Eastbourne was 1,900, and at Kensington 2,000. At Eastbourne their mains were copper, insulated with vulcanised indiarubber, and a small portion of them were lead covered, insulated with cotton, saturated in some compound. They used cast-iron pipes for the purpose of laying their mains in, which answered very well indeed. At Eastbourne they made tests every morning for insulation. Knowing the inadvisability of having to stop every day each circuit to test it with a Wheatstone bridge, they hit upon a small device, which showed at a glance whether the insulation was good or bad. It simply gave a proof test that there was no leakage going on. He was a very great believer in this company's system. He believed that the battery system was expensive, and he thought it offered no points of safety over an alternating system with thorough subdivision. The subdivision of plant was a very important point. One very great advantage was that as the load upon the plant increased they could put on one unit after another, and therefore keep the engines working up to a fair state of efficiency. The plant in motion at a particular time would be so arranged that whenever one portion stopped another would be ready to do the work. The portion of the plant could be cut out automatically if it was wrong before there was time given to detach it. If it did not give sufficient notice for it to be detached, it would cut itself out automatically. He also considered it a great advantage to have a subdivision of distributing mains. It was equally necessary with the subdivision of plant. The result of that was that there could be no chance of their leaving the whole of their district in darkness at any one time. In the early stages of the converter system, before it was actually known what was required to protect converters, there was always a danger of the converters burning out. With the fuse that they were using now he was quite at liberty to short circuit any converter that anyone liked to point on their circuit when the lights were running.

Cross-examined by Mr. Moulton, he said that from tests taken at Eastbourne, and also at Brighton, he found that the loss of electricity by the ordinary use of batteries was fully 30 per cent.—that was in actual practice; he did not mean laboratory tests.

Major Cardew: Is this loss of energy?

Witness: Yes; loss of energy.

Major Cardew: He asked for electricity.

Mr. Moulton: I meant loss of energy, of course.

Witness said that if the direct supply was only 100 volts, as against 2,000 volts pressure, he thought the cables would be enormously large unless the cables were made more in number, which would amount to the same thing. Under identical conditions and practice, the mains for direct supply for 100 volts would have to be 400 times the size of what the mains had to be for a high-tension 2,000 volt supply.

Major Cardew: As regards the question of burning converters, is it not the case that the danger of burning out would be

Digitized by Google

much increased by the use of wires with inferior insulation in the house circuit?

Witness: Undoubtedly.

Major Cardew: Would you consider wires merely covered with cotton, even if saturated with paraffin, inferior wires for house service?

Witness: I should advise my company not to connect their system on at all—in fact, they would not do it with cotton-covered wire.

Prof. G. Forbes, recalled and examined by Mr. Shiress Will, said that from a general view of the condition of Kensington he should say that the alternating-current system with converters was certainly the best. It was perfectly possible to run alternating-current dynamos on the same current. That had been known for a long time. He first saw alternating-current dynamos on the same circuit at at the South Foreland Lighthouse. Prof. Adams made one actually drive the other as a motor. They synchronised perfectly. That enabled them to switch on a dynamo when the load increased without affecting the others, or to switch one out when anything went wrong with it without affecting the light in any way whatever. He had seen it done at the House-to-House station without the slightest flickering of the lights. He tested it under very severe conditions indeed, and the way the parallel working succeeded at the West Brompton station was absolutely unexceptionable. There was not the slightest doubt of its being capable of being applied in regular work. He had put it under much more severe tests than doing it under heavy loads. He had known dynamos which worked perfectly well with a heavy load, and when they were put on a light load they would run synchronously certainly, but one dynamo was always gaining a little bit over the other, a portion of the phase, so that the light had a trembling appearance. He had seen that with some dynamos working in parallel even with a light load, but when it was done with a light load there was not the slightest tremble. He might say that he put on 100 kilo-watt dynamos as low a load as about 5 h.p. without the slightest variation or trembling of the light. He then worked those two together on a single lamp, only one lamp being on circuit, and it was just barely possible to see the flicker. They could just occasionally see a little trembling in the light with only some single light on those two dynamos. He carried out the experiment himself.

THURSDAY, APRIL 18.

Prof. W. Crookes, called and examined by Mr. Wallace, said he was chairman of the Notting Hill Electric Lighting Company, and that his house had been lighted by a private installation for seven or eight years. His friends had combined to establish a small company to introduce the electric light into the neighbourhood. They had raised only a small amount of capital by way of preliminary expenses, and had not made any effort to get more from the public. The nominal amount of the capital of the company was £100,000. His company were before the Vestry of St. Mary Abbotts and Kensington, with other companies, for about 12 months. The company had been floated according to the form prescribed by law.

Mr. Wallace then opened his case for the Kensington Court and Kensington and Knightsbridge Electric Light Companies, and in the course of his address said that the Kensington and Knightsbridge Company had been in existence for a year and a half, having taken over the Kensington Court Electric Light Company. The two companies now asked practically for the same area. The Kensington Court Company was still in existence, but it was the same company as the Kensington and Knightsbridge Company, which arose in this way; the Kensington Court Company were in possession of the licenses granted by the Board of Trade, and the Kensington and Knightsbridge Company taking over the Kensington Court Company thought it advisable to apply to the Board of Trade in the name of both companies, in case there should be any technical difficulty in transferring the property from one company to the other. They had two stations, one situated at Kensington Court and the other in Chapel-street, on the north side of Brompton-road. He might say that if the inspector would cast his eye over the Chelsea map he would see that, although the area looked rather large, it really was not more than one square mile. In opening his case, he wished to say that they had been very much indebted to Mr. Crompton and his firm for the very great attention that they had given to the development of electric lighting in the district in which they had been working for the past three years. Another gentleman that he wished to refer to was Mr. Metcalfe, who, from the very inception of the Kensington and Knightsbridge Company, had been of very great assistance to them, because they had not been like the other companies, who were promoting orders and acting in a manner which they would not have been allowed to do provided they had been working under provisional orders. His company had been acting according to the provisions of the Board of Trade, and in their long negotiations with that body Mr. Metcalfe had been of the greatest service to the company. He did not wish in any way to go over the ground that had been traversed so frequently during the course of the enquiry by the other promoters, but he thought there was a slight difference between the policy which the Kensington and Knightsbridge Company advocated, and that promoted by the other schemes. They might divide the promoters into three classes. There were those who desired to have concurrent powers over the same area; there were those who, in the second place, believed in districting, and that the capital of the undertaking should be raised as far as possible within the district itself, and the stations should be situated close to the area of supply. That was the policy that the Kensington and Knightsbridge Company advocated—that the residents in the district should find the capital necessary to carry on the work, and that the district should be lighted from stations in the immediate vicinity. In saying that it would be seen that there was a difference between them and the other promoters who had advocated a series of stations apart from one another, and which, according to the experience of the Kensington and Knightsbridge Company was, perhaps, unwarranted—that was to say, the other promoters proposed to make generating stations far too large for the district in which they carried on their works. With regard to the concurrent powers, he thought it was necessary for him to mention that in his company's district they had streets very similar to those that had been spoken of by the local authorities for the Strand, and the various other witnesses that had been cross-examined at the enquiry. In High-street, Kensington, they had a great thoroughfare where the traffic was, to a very great extent, congested, and there was the same kind of mains under it as they found in the Strand and other places, such as gas, water, hydraulic, telephone, and telegraph mains, and it would be a very serious matter to his company if the mains of other companies were allowed to pass through the same conduit because his company's mains were not insulated, being bare copper strips. Therefore, they very much objected to have rival companies in the area. He believed that districting would be the best plan, for it seemed to him if rival companies were to be in the same district the very streets that they would make for would be those where the traffic was congested, because there were more shops and such places to be lighted, and such places would form the battle-ground between them. As to the result of competition, Mr. Moulton had put the matter much better than he could do. It would not do to allow those companies advocating districting to be interfered with by another company, such as the Metropolitan, which, according to its proposals, would interfere with the Kensington and Knightsbridge position of the Knightsbridge Company's district, and in the event of failure nobody would be hereafter able to judge in any case what the cause of it was. At Kensington Court they used Babcock's boiler, Willans' engines, and Crompton's dynamos and batteries, the latter being used for giving a limited supply of electricity in the case of a breakdown in their plant. Coming to the question of smoke nuisance, his company had got over the difficulty by using Welsh coal, whilst as regarded vibration, they found from experience that no sensible effect was experienced. He thought that when the inspector visited their works he would find that there was no danger on the score of vibration. As to safety, he ventured to say that his company occupied the best position. As to the coal-carts' nuisance the total quantity of coal that would be used would be 16 tons a day, which could be conveyed in eight carts, which could not in any way interfere with the traffic.

Mr. R. S. Erskine (secretary to the Kensington and Knightsbridge Company) was then called and examined by Mr. Wallace, and said that the company was started in 1886 with a capital of £10,000. It was formed with the intention of lighting Kensington Court. The Knightsbridge portion of the license was obtained in 1883. A great portion of the district was already covered by license. All the money had been found by the directors, none by the public. £57,000 had now been paid up. About £75,000 more was promised, which would be available as required. Mr. Wallace's opening speech was a general description of the works without going into details. The only competitor they had in their district was the Metropolitan Company, which had done nothing there up to the present time in the way of practical work. There had been a considerable demand for the light in the district. They had promised to begin to supply light by the middle of May under the 1888 license. There had never been any nuisance at their two stations which they had not been able to obviate in a day or two. Although no dividend had been paid, the company was being worked at a profit.

Cross-examined by Mr. C. A. Cripps, **Witness** said that the actual capital expended was within two or three thousand pounds of what had been paid up. They had never a large balance at the bank, as the amount paid up was immediately spent on plant and mains. Their district would be supplied by a circuit connected with batteries at a central station and outlying stations in the centre of the district. The sectional area of their largest distributing mains was over half an inch. The most of them were between ¼in. and ½in. in sectional area.

Mr. Wallace afterwards briefly opened his case on behalf of the Westminster Company, pointing out that the company had already established itself at Victoria-mansions, where it had a site possessed by a director of the company, and where they had placed plant from which they would be able to supply 5,000 lights in the neighbourhood. The only difficulty the company felt was that of supplying the district of Mayfair, which would be a considerable distance from their proposed station.

CITY NOTES.

Direct Spanish Telegraph Company.—The receipts of this Company for April were £1,867, against £1,800.

Change of Address.—The Monte Video Telephone Company, Limited, have removed to 25, Abchurch-lane, E.C.

South of England Telephone Company, Limited.—This Company have declared a dividend of 6 per cent. per annum on the preference shares for the half-year ending April 30.

West India and Panama Telegraph Company.—The receipts for the half-month ended April 30 were £3,410, against £3,337. The January receipts, estimated at £5,151, realised £5,354.

London Platino-Brazilian Telegraph Company, Limited.—A meeting of this Company was held last week at the offices, 19, Great Winchester-street, E.C., to which representatives of the Press were refused admittance.

Western and Brazilian Telegraph Company, Limited.—The Directors of this Company, after placing £7,000 to renewal fund, £6,400 to debenture redemption fund, and writing off the rebate on issue of debentures—viz., £26,100, recommend a dividend of 9s. per share, tax free, making with the interim a total distribution for the past year of 5 per cent., as compared with 4¼ per cent. for 1887.

NEW COMPANIES REGISTERED.

Pontypridd Electric Lighting Company, Limited.—Registered by Drake, Driver and Leaver, Limited, with a capital of £10,000 in £5 shares. Object: to generate and supply electricity, electric light, and electric power in Pontypridd and Ystradgfodwg for public or private purposes. The first subscribers are:

	Shares.
H. Hopkins, Fairlawn, Pontypridd	1
R. Evans, Pontypridd	1
W. Williams, Market-square, Pontypridd	1
D. Evans, Taff-street, Pontypridd	1
D. Cull, Mill-street, Pontypridd	1
W. Merchant, Pontypridd	1
W. Morgan, Pontypridd	1

Registered without articles of association, and, consequently, the regulations of table A in the first schedule of the Companies Act, 1862, apply.

Jensen Electric Manufacturing Company, Limited.—Registered by Batten, Proffitt, and Scott, 32, Great George-street, S.W., with a capital of £80,000 in £5 shares. Object: to carry out an agreement, dated April 26th, made between Clifton Shield and C. F. Helder of the one part, and J. M. M'Donnell, as trustee on behalf of the Company, of the other part. The first subscribers are:

	Shares.
J. Proffitt, 32, Great George-street, S.W.	1
F. Wall, 16, Temperley-road, Balham	1
V. Lambley, 35, Crondrel-road, Fulham	1
J. Young, 54, Cheriton-square, Tooting	1
F. Galsworthy, 8, Smith-square, S.W.	1
A. Scott, 32, Great George-street, S.W.	1
C. Jones, 32, Great George-street, S.W.	1

The regulations of table A in the first schedule of the Companies Act, 1862, with slight modifications, apply.

Electric Tramcar Syndicate, Limited.—Registered by Davidson and Morris, 40 and 42, Queen Victoria-street, E.C., with a capital of £20,000 in £10 shares. Object: to acquire the letters patent granted to A. J. Jarman for an invention for "improvements in the construction of electromotors for the propulsion of tramcars, electric locomotives, vehicles and other purposes." The first subscribers are:

	Shares.
H. J. Hemmerde, 15, Lee-park, Blackheath	50
J. Hemmerde, 10, Elliot-place, Blackheath	50
J. Muirhead, 23, Regency-street, S.W.	10
H. Archer, 31, Lombard-street, E.C.	1
A. Hemmerde, 10, Elliot-place, Blackheath	10
Captain La Feuvre, 235, High-road, Lee	1
W. Harris, 136, Drayton-park, Highbury	1

The number of Directors shall not be less than three nor more than seven. The first are J. Muirhead, P. E. Lentilhac, and H. J. Hemmerde; H. Archer, if willing to act, shall be appointed after completion of purchase. Qualification, £500 stock. Remuneration to be determined in general meeting.

PROVISIONAL PATENTS, 1889.

FEBRUARY 27.

3487A. **Improvements in means for actuating signals, switches, and gates on electric and other railways.** Robert Cooke Sayer, 11, Clyde-road, Redland, Bristol. (This application having been originally included in No. 3,487, dated 27th February, 1889, takes under Patents Rule 23, that date.)

3487B. **Improvements in means for supplying electric current to road vehicles, boats, and the like.** Robert Cooke Sayer, 11, Clyde-road, Redland, Bristol. (This application having been originally included in No. 3,487, dated 27th February, 1889, takes under Patent Rule 23, that date.)

APRIL 29.

7088. **Improvements in electric measuring instruments.** Robert Snowdon, Staveley Iron Works, Chesterfield.

7108. **Improvements in safety devices for high-voltage circuits.** Bernard Mervyn Drake and John Marshall Gorham, 2, Prince's-mansions, Victoria-street.

7127. **Improvements in or connected with the brush contacts of electric railways.** George Edward Vaughan, 57, Chancery-lane, London. (Samuel Trott, Nova Scotia.)

7129. **Improvements in arc electric lamps.** Arthur James Howes, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

7133. **Improvements in electric meters.** Anthony Reckenzaun, 28, Southampton-buildings, Chancery-lane, London.

7138. **Improvements in and connected with electric glow lamps.** Arthur Willington Fitch, 4, South-street, Finsbury, London. (Richard Oliver Gardner Drummond, South Africa.)

APRIL 30.

7165. **Apparatus for electrical distribution of energy.** John Macintosh Mackay Munro, 136, Bothwell-street, Glasgow.

7183. **Improvements in actuating points or switches in connection with the operation of the signals.** Cuthbert Ellison Carr, 46, Lincoln's-inn-fields, London.

7198. **Improvements in the manufacture of electric arc carbons.** Walter Ernest Adeney and Llewellyn Saunderson, 24, Southampton-buildings, Chancery-lane.

7215. **Improvements in secondary batteries.** Charles Barnard Askew and James Kent Pumpelly 1, Queen Victoria-street, London. (Complete specification.)

MAY 1.

7275. **Improvements in arc lamps.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, Chancery-lane.

MAY 2.

7336. **Improvements in apparatus for electrical communication for trains and similar purposes.** Arthur Cecil Cockburn and John Nealor Cooper, 32, Gaisford-street, Kentish-town-road.

7337. **Improvements in electric winding and striking clocks.** Joseph Jacomin, 46, Southampton-buildings, Holborn. (Complete specification.)

7349. **Improvements in the methods and means of working the driving appliances on electrically propelled vehicles.** Michael Radcliffe Ward, 9, Warwick-street, Regent-street, London.

MAY 3.

7356. **Improvements in galvanic or primary batteries.** Charles Maltby-Newton, Holly Lodge, Windmill-road, Croydon. (Complete specification.)

7395. **Improvements in or relating to commuting alternating currents of electricity.** Wilfrid Swanwick Boult, 24, King's-mount, Birkenhead.

7405. **Improved means for utilising terrestrial and atmospheric electricity for the production of motive power and other purposes.** Enrique Cortes, 191, Fleet-street, London. (Rafael Zerda Bayon, South America.)

7416. **Improvements in devices and apparatus for controlling and regulating motive power for various purposes, but having especial reference to the use of electric motors for training heavy guns.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Middlesex. (Bradley Allan Fiske, United States.)

7423. **Improved means or apparatus for driving rotary hair brushes and the like by electricity.** Herbert John Dowsing and Henry Sherley Price, 115, Cannon-street, London.

7428. **Improvements relating to electric accumulators or secondary batteries, and to the manufacture of plates or electrodes therefor.** Charles Pollak, 45, Southampton-buildings, London.

MAY 4.

7473. **Improvements in switch apparatus for electrical circuits.** Charles Ambrose McEvoy, 28, Southampton-buildings, Chancery-lane, London.

7475. **An improvement in telephonic signal apparatus.** Charles Butler Clay, 28, Southampton-buildings, Chancery-lane, London.

7499. **Improvements in the method of and means for producing low tension alternating electric currents and applying same to sundry purposes.** Edward Manville and William Leonard Madgen, 1, Queen Victoria-street, London.

7506. **Improvements in the electric lighting of railway trains.** Illius Augustus Timmis, 2, Great George-street, Westminster.

7507. **Improvements in mechanically and electrically working, repeating, and interlocking railway points and signal apparatus in conjunction with block instruments and the lighting of signal and station lamps.** Illius Augustus Timmis, 2, Great George-street, Westminster.

SPECIFICATIONS PUBLISHED

1888.

NOTES.

Sebastopol.—The Municipal Council of this town has decided to adopt the electric light. Tenders will be invited shortly for the lighting of the town.

Electricity in Churches.—The three organs in the Church of Saint-Jacques-du-Haut-Pas, at Paris, are to have an electro-pneumatic attachment, so that one organist can play the three organs simultaneously.

The Passion Play.—This play, which, as is well known, is usually given at Oberammergau, in Bavaria, is to be played this year at Brixlegg, in the Tyrol. The scenes and tableaux will be illuminated by the electric light.

Exeter.—The Exeter Electric Light Company have offered to supply tradesmen first and private residents next with their light free of charge for the first two months of the installation. The erection of the works for the central station in New North-road is making considerable progress.

Vienna.—An international company has been started in Vienna for the purpose of supplying the streets and private houses with the electric light at the least possible cost. The capital of the concern is five millions of florins, and the issue of the shares will be made by the Union Bank of Vienna.

Lighthouse Illumination.—A new committee of the Royal Society has been formed, consisting of the President (Prof. Stokes), Sir William Grove, and Lord Rayleigh. The committee are to decide whether the conclusions of the Trinity House on lighthouse illuminants are justified by the experiments.

Vestries and Telephone Wires.—At the St. George's Vestry attention was called to the overhead wires of the telephone company at Vauxhall-bridge-road. It was mentioned that the permission of the Vestry had not been asked; they had no control over them, or many of them would be pulled down.

The Institution.—At the next meeting of the Institution of Electrical Engineers, on May 23, a paper will be read by Mr. W. M. Mordey, "On Alternate Current Working," which may be expected to fully deal, amongst other things, with the principles and construction of the Mordey alternator.

Spain.—Tenders will be received up to the 20th inst. by the Minister for the Colonies at Madrid for the establish ment of three submarine cables to be laid between the islands of Luzon, Panay, Negros, and Cebu. The total length is about 207 miles, and the basis of the estimate is 1,100 pesetas (£41. 5s.) per mile.

Edison's Bamboos.—Some year and a half ago Frank McGowan was sent by Edison to the wilds of South America to find, if possible, the ideal bamboo for the incandescent lamp filaments, one which should be tough and durable. It is asserted that Mr. McGowan has succeeded in his quest, after almost incredible adventures and sufferings.

Conundrum for Young Electricians.—Given these conditions: A telegraph cable of 900 miles in length between two foreign ports A and B. The instruments at B have gone wrong, and others cannot be procured. The only instruments available are an astatic galvanometer, a shunt-box, and a battery. B has to take his test for the insulation resistance of the cable. What is B to do to obtain an approximately accurate test from his end?

Searching for Treasure.—Captain Ponsonby, who has actually trod the decks of "L'Orient," the French battleship sunk by Nelson at Aboukir, and now lying submerged in the same place, is going out with selected divers to search and attempt to recover the treasure known to be on board. A limited company has been formed to provide funds, and to take over the concession already obtained, and dynamos and lamps will be taken out to continue the search uninterruptedly by electric light.

Killed by an Electric Shock.—An extraordinary case of accidental death by electricity is reported from America. Mr. Vincent, a well-known citizen, and brother of Bishop Vincent, of the Methodist Church, being in a low state of health, conceived the idea of treating himself by electricity. Instead, however, of procuring the ordinary medical electrical appliances, he rashly interfered with the mains of one of the electric light and power companies, and received a shock which killed him as quickly and as surely as lightning.

Tender for Shanghai. — The authorities of the French Concession at Shanghai, China, are inviting tenders for the lighting of the said concession by a system which shall commend itself as best for lighting and actual cost. The contracts are to date from April 1, 1891, for a term to be decided upon for each tender. Tenders are to be sent to Shanghai before December 31, this year, and all further particulars can be obtained of the Engineer of the French Municipality at Shanghai, or of M. A. Servant, 6, Rue de Braque, Paris.

Railway Telegraphic Facilities.—Mr. Raikes, in answer to a question in the House of Commons on Monday, said that he had already stated that there were nearly 1,600 railway stations open for the transaction of telegraph business on behalf of the Post Office. Arrangements are continually being made with the railway companies to open additional stations for telegraph business where there are the necessary facilities for transacting it; and the authorities would always be glad to communicate with the companies in regard to any reasonable application for such facilities.

Electricity Not a Material.—Judge Simonton, at Harrisburg, Pennsylvania, in a suit by an electric company to avoid taxation, has decided that electricity is not a material substance. From this it follows that electric light companies are not manufacturing corporations within the meaning of the Act, and are therefore not exempt from taxation. He holds that the term "manufacturing" cannot be properly applied to any corporation not producing material substances, and neither electricity or electric light being material, the Act imposing a tax is upheld as constitutional.

New Railway Block System.—A Madras paper states that "the model of the new railway block system, invented by Mr. Wale, telegraph master, Madras, who has taken out a patent for the system, has arrived from England, where it was made by Messrs. Siemens Brothers, the electrical engineers. It was exhibited at the Central Telegraph Office on the Beach on Monday last, and was inspected by Mr. F. G. Maclean, superintendent of telegraphs, who expressed himself well pleased with the instrument. The inventor claims for his system, which is by no means complicated, several advantages over any of the block systems now in use."

Post Office Telegraphs.—A Parliamentary paper has been issued under the heading of "Additional Estimate,"

Digitized by Google

containing an estimate of the additional amount required in the year ending March 31, 1890, to defray the expenses connected with the acquisition of the Submarine Telegraph Company's property required for the Post Office telegraph service. The amount required is £67,163, which is accounted for under the sub-heads of cables, buildings, cable ships, instruments, and stores, bonus for officers of the company not taken into the service of the State, interests, etc. The appropriation in aid, which is deducted from the gross total of £81,313, amounts to £14,150.

Thomson-Houston Lamps in Paris.—We learn from Paris that the representative of the Thomson-Houston Company in that city has secured a large proportion of the street lighting, and that the arc lamps on this famous system were started for the first time on Saturday night in the Place de la Concorde. Large contracts are also in hand for incandescent lighting, which will be carried out on the Thomson-Houston alternating system. Although Paris was the first to adopt arc lights in her streets on the Jablochkoff system, these had a very brief enjoyment of public utility, and the Thomson-Houston arc lamps are the first public electric lights that have been seen in Paris for many years.

Competition.—The Dutch Electrical Society (Harlem) invite competitive answers, to be sent in up to January 1, 1890, to the following questions: 1. Experimental or theoretical research upon known phenomena of electrodynamics and induction. 2. Experimental determination, by one or more methods, of the influence of compression in the direction of the E.M.F., and perpendicular to that direction upon the power of the specific inductor. Replies, in Roman character, may be written in Dutch, French, Latin, English, Italian, or German, and must be accompanied with a sealed envelope containing the name and address of the competitor. They must be addressed to the secretary of the society, Prof. J. Bosscha, Harlem.

The Southwark Electric Railway.—The preliminary experimental train for the London and Southwark Subway will be tried, it is expected, in about three weeks' time. Messrs. Mather and Platt, who have the work in hand, are sending down the necessary machinery and plant, and a temporary power station will be instituted for the trial of the system, somewhere between London Bridge and the first station. The experimental train will be run on the first section of the line, and it is hoped to have the matter sufficiently perfect to have a press view of the trial for the technical journals. It may be well to mention, once for all, that we are informed there is not the slightest intention of the company to run any part of the line by the ordinary cable system.

Combined Town Plants.—The Heisler Electric Light Company, of St. Louis, U.S., has entered into a contract with an Illinois electric light company for an electric light plant to supply the three towns of Ottawa, Marseilles, and Seneca, Illinois. The station will be situated at Ottawa, as the centre point of the system, from which all three of the towns will be furnished with street and commercial lights. Long-distance lighting is one of the special features of the Heisler system, and the example here given, probably the first of its kind, of several towns uniting for the supply of a long-distance series incandescent service, may be worthy of imitation where there are several small towns or villages sufficiently near and sufficiently neighbourly to co-operate in this manner.

Magnetic Viscosity.—Mr. Thomas T. P. Bruce-Warren has found that if a magnetic substance like soft iron be covered by different liquids, not only is its susceptibility modified by the permeability of the intervening medium, but there is distinct evidence of a molecular stress being produced on the medium, and which indicated itself in the case of one experiment by decided tendency of a balanced magnet to stick, as it were, when allowed to remain for a short time over the soft iron. Mr. Bruce-Warren thinks that this is due to the fact that the maximum effect of a magnet on soft iron depends on the rapidity with which the medium accommodates itself to the constrained condition necessary for the soft iron to take its greatest degree for magnetisation. He calls this "magnetic viscosity."

Westinghouse Opens the Campaign.—Westinghouse has commenced proceedings in France, where he is about to form a company with a capital of one million sterling. The company is to erect and fit up a number of works for the manufacture of plants (steam-engines, dynamos, transformers, meters, lamps, etc.) for supply to central stations. It also proposes to compete for the lighting of the Parc Monceau, the Champs-Elysées, and a section of the left bank of the Seine. A well-informed Yank, who professes to know all about it, says that Westinghouse is also awaiting the result of the Board of Trade enquiry, not that he hopes much from it, but it may make matters more difficult for him, and therefore give him a chance of showing what America can do when she is put to it. Look out, electric lighting companies.

Electric Lighting in Holborn.—At the last meeting of the Holborn District Board, Messrs. Rooper and Co. wrote asking the consent of the Board to an application to the Board of Trade for a licence to allow Gwynne's Pilsen Lighting Company to supply electricity in the district. A representative, who attended in support of the application, said that it was the only one of the electric lighting companies supplying the district that had works in Holborn. The company had taken large premises in Leather-lane, and when they were in full working order, they would not only produce a large revenue to the Board in rates, but would also bring a lot of trade. In reply to a member, the speaker said that the company was at the present moment supplying the district from their premises in the Euston-road. If the Board gave their consent, and the licence was granted by the Board of Trade, it would invest them with compulsory powers. The chairman said that there were many things to be considered in connection with this matter, so he thought the best course to adopt was to refer it to the Committee of Works for consideration and report.

The Eiffel Tower and the Spectroscope.—The Eiffel Tower may be said to have commenced its expected career of usefulness as an aid to scientific investigation in a sufficiently startling manner. According to the Paris correspondent of the *Daily News*, M. Jansen, of the Academy of Sciences, claims to have made a discovery which upsets the entire theory based on the analysis of celestial bodies by means of the spectroscope. Last Sunday the electric lamps of the Eiffel Tower were turned on the Meudon Observatory, which is 7,800 metres (four miles seven furlongs) away. He reckons that the mass of air lying in a given section of that length at the height of the tower is equal to the atmospheric mass above. M. Jansen argues from this that the number of molecules of air encountered by a beam of light sent from the Eiffel Tower to the Observa-

Digitized by Google

tory is about the same as that met by sunlight on its way to the earth when the sun is near the zenith. He then shows that, if the analogy holds true, the belief that the sun contains oxygen is unfounded, and that if its spectrum contains the characteristic oxygen rays, this is due to the oxygen of our atmosphere. One of the fundamental theorems of spectrum analysis is that the width of the characteristic bands of a gas is proportionate to the number of molecules that intercept the light. Now, in last Sunday's experiment the most important rays of the oxygen group were precisely similar to those of the solar spectrum. The conclusion M. Jansen draws is that there is no oxygen in the sun.

Brooks' Underground Conductors. — Some particulars are forwarded to us, by Mr. David Brooks, of the comparative expense of the Brooks system of underground electrical conductors as compared with other systems. In the Brooks system the insulation is poured in at the time of laying, in the form of a thick resin mixture. For telephones on the ordinary system, with creosoted hemlock conduit and lead-encased cable for 100 wires, the cost is worked out at about £7 per conductor per mile ; and with iron pipe 3in. diameter, instead of wood, £9. With the Brooks system, the 3in. iron pipes will take 225 conductors, and the cost per conductor per mile is given at £4. 5s. For underground circuits for arc lighting the figures given are equally favourable. The cable of the Pennsylvania Railroad was laid two years ago on this system with 53 conductors, and there has never been a single interruption. Conductors for practical use were laid on the London and South-Western Railway nine years ago, and are certified by Mr. Preece as working without any trouble. Paraffin oil was used at first in this system, but the thick mixture of resin oil has now been substituted, and any slightly defective point will show no leak at all. The laying of the Brooks system is so simple and easily performed that it is the intention of the company to grant licenses to those who wish to use it, and let those parties do the work. Instructions and terms can be furnished on application to the Brooks Underground Telegraph Construction Company, Limited, 307, Walnut-street, Philadelphia.

The Birmingham Electrical Exhibition.—Preparations for the Electrical and Industrial Exhibition at Bingley Hall are being pushed forward with most satisfactory rapidity, and already nearly the whole of the space already available for exhibitors has been let. In the electrical department most of the best-known firms of electrical engineers and manufacturers of electric appliances will be represented, among them the Edison-Swan Company ; Anglo-American Corporation ; Messrs. Woodhouse and Rawson, Limited ; Elwell-Parker, Limited ; Laing, Wharton, and Down ; the Gulcher Electric Light Company, Limited ; the Planet Electrical Engineering ; the Julien Company ; Messrs. Fowler, Lancaster, and Co.; Shippey Bros.; Ernest Scott and Co.; Mr. Julius Sax; and the Acme Electric Works. The exhibitors in the steam-engine section will include such well-known firms as Messrs. Robey and Co., Ruston, Proctor, and Co., Galloways, and Greenwood and Batley. The general exhibits, of which there are several hundreds, will include some interesting manufacturing processes, such as ribbon-weaving, metal-plating, pen-making, breadbaking, bootmaking, etc. Messrs. Halmshaw, of Small Heath, Birmingham, are building a large three-manual organ for the exhibition, and the executive committee have engaged Mr. Gilmer's excellent military band to give two performances each day during the time the exhibition is open. The North-Western, Great Western, and Midland Railway Companies have promised to run cheap trains to Birmingham at frequent intervals, to give country people a chance of seeing the exhibition.

Uruguay.—A pamphlet has reached us from the Consulate of the Republic of Uruguay, 27, Throgmorton-street, E.C., which it would be well for manufacturers and shippers generally to ponder well. This republic is at the present moment in a state of intense commercial activity, and the whole country has been likened to a vast workshop. Buildings are springing up in all the cities, Monte Video and Rosario being the largest. Important undertakings of all kinds are in progress ; stores, stations, manufacturies, etc., in profusion are laid out and being erected. The demand for electric light is shown in the fact that at the Arroyo Seco, in Monte Video, a large electric light station is being constructed. The work is already far advanced, and in a short time will supply the public lighting of the whole city. Private buildings will also need the light, and the opening is apparently large for all kinds of electrical apparatus for business uses and the saving of labour. Three new tramways are to be opened this year, but whether electricity is to be employed at present does not appear. Telegraphs are laid, to the extent of 3,695 kilometres, by means of which all parts of the republic are in direct communication with each other. Telephones are particularly well patronised ; Monte Video with a population of 140,000 has 2,226 subscribers, and Rosario (51,000) has 1,546, being respectively 159 and 304 subscribers per 10,000 inhabitants. When it appears that the same proportion for Berlin is only 48, and Paris 21, it seems that Uruguay is wonderfully well developed in telephonic ways. It may well be anticipated that an equal and immediate development will take place in other branches of electrical engineering.

Electric Power from the Rhine.—An enterprise of considerable magnitude is under practical consideration, for the purpose of utilising the water power of the Rhine at Rheinfelden, for the distribution of power for commercial purposes throughout the adjacent district. Three large Swiss firms have combined to carry out the preliminary negotiations—namely, Zschokke and Co., of Aarau; Escher, Wyss, and Co., of Zurich; and the Oerlikon Company, of the same town. The village of Rheinfelden is about ten miles from Basle, and the Rhine, which here forms the boundary between Switzerland and Baden, would furnish, after the erection of the necessary plant, a power of some 15,000 h.p. This force would be distributed among the various industrial centres, which are numerous in this vicinity, with a radius of about 15 miles. For this purpose it is proposed to erect 20 turbines, each of 750 h p., coupled direct to Brown dynamos of 500,000 watts, producing 250 amperes each at 2,000 volts. Several of these would be connected in series, giving a total pressure of 4,000 to 8,000 volts for the distributing mains, reduced to the necessary potential for use at various secondary centres. The preliminary work being now finished, the proposers of this scheme are asking for a concession from the Grand Duchy of Baden for the purpose of erecting their station at Rheinfelden. The financial side of the scheme is regarded as satisfactorily settled, and the execution of the project will only depend upon the attitude of the authorities. It is hoped that a scheme of these dimensions, meaning, as it does, a very large step in advance in the application of electricity to the distribution of power for industrial purposes, will meet with the encouragement it deserves, and that the Govern-

Digitized by Google

ment will grant the concession to these enterprising engineers.

Tenders for Electric Lighting.—The following tenders were sent in on the 8th inst. for the electric lighting of the Meirelbeke Station (Belgium) and its dependencies, and of certain portions of the central works at Gendbrugge: Legros Fils (Namur), 82,124f., 45 h.p. dynamos, 180 amperes, and 70 to 100 volts, with 775 revolutions; lamps and dynamos Zurich Telephone Company's system; guaranteed light 55 and 65 carcels per h.p. week.—Société Industrielle d'Electricité (St. Gilles), 124,474f., 40 h.p. dynamos, 180 and 15 amperes, and 65 to 400 volts, with 1,000 and 1,500 revolutions; Lahmeyer machines; Piette and Krizik, or Matisse and Bouverolle lamps; 102 and 76 carcels.—Société du Phénix (Ghent), 54,999 or 89,999f., 30 h.p., 66 and 91 amperes, and 220 and 65 volts, with 1,200 revolutions; Edison's machines; Halfat or Piette and Krizik lamps; 80 and 74 carcels.—Thomson-Houston International Electric Company (Ixelles), 51,819.60 or 40,837f., 24 or 18 h.p., 7 or 88 amperes and 825 or 60 volts, with 950 or 1,500 revolutions; machines and lamps, Thomson-Houston, 2,000 and 1,400 c.p., or 100 and 50 carcels.—Société Electrique (Laeken), 66,729f. (1), and 59,790f. (2), 45 h.p., 40 h.p., 600 and 1,200 revolutions, producing 80 and 105 amperes, and 250 and 60 volts, or 1,000 revolutions, producing 15 amperes—500 volts; machine, Victoria Compound and Brush and Victoria; lamps, Brush and Weschleer for both projects, 55 and 50 carcels (1), and 60 and 50 carcels (2).—Soc. Anon. d'Electricité et Hydraulique (Charleroi), 55,283.30f.; project (1) and 88,673.30 (2), 15 and 22 h.p., 500 and 625 revolutions, 140 amperes and 65 volts; and 900 revolutions, with 60 amperes and 225 volts.; Dulait machines and lamps, 55 and 58 carcels.—L. Bouckaert and Cie. (Schaerbeek), 8 proposals, 83,209.75f. to 49,700f.; Schuckert dynamos and Piette and Krizik lamps, 63 to 79 carcels.

A Universal Telegraphic Language.—The extreme cost of sending international messages by cable has prevented persons in general from using this facility for communication, except in the case of urgent necessity where cost is no object, and has to a large extent reserved their use to millionaries or large business houses. M. Léon Roquet has recently submitted to the French Minister of Telegraphs a project for a universal telegraphic language, which would afford a large benefit to the public for the cheaper transmission of cable messages. In the ordinary telegraphic dispatches there are a large number of phrases, conversational, financial or official, which occur time and time again. M. Roquet proposes that these constantly recurring phrases should be tabulated under certain conventional combinations of letters and figures. These ordinary words and phrases being similar in all languages, the same letter and figure would also serve for the same idea or thought by persons of various nationality, and thus form a real universal language, not spoken, but written, a "telegraphic language." He proposes to search the files of the last few years, noting the usual forms employed. These he would tabulate in the pages of a book, in columns, which should be headed with the letters of the alphabet, the phrases on each page having the numbers from 1 to 50. The book might contain, if necessary, a couple of thousand pages arranged for use in various departments, and in telegraphing, the message would read som thing like this "fk 2, d 3," etc. An ordinary message would contain only the number of letters or signs of a single word, or perhaps two, the message being written out in full at the receiving end. The cost of a cablegram, varying in cost at the present rates of from 6d. to 20s. per word, is now almost unthought of luxury for ordinary purposes, would be within the scope of private means, and at the same time greatly reduce the cost of official or financial transactions.

Increasing the Output of Transformers.—At Pittsburgh, it is announced that the experiments have been made, before some prominent gentlemen of that city, by Mr. E. G. Acheson, by which the output of transformers can be increased one hundred per cent. by the application in some manner of "heat, pure and simple." Mr. Acheson has been at work for several years in the problem of the direct conversion of heat, and regards one part of it as definitely solved. The invention is stated to cause the heat to impress converted energy upon an alternating circuit, in which electricity is already flowing, by the simple application of flame. The following is given as the account of an eye-witness: "An alternating current flowing through the circuit was measured and its total energy determined by careful calorimetric time-tests, which were checked by a simple form of Cardew voltmeter. The heat was then brought into play without any alteration of condition, so that the only possible variable in the combination would be the current due to increase of E.M.F. This took place at once at every repetition of the test, and the checking readings all corroborated each other accurately. The total energy thus measured was in every instance found to be upwards of one hundred per cent. greater than when the heat was absent." The writer, who, by-the-bye, does not give his name, says the process can be made cumulative, and increase can be obtained far beyond doubling the capacity. He points out the vast possibilities of the invention, in that a 500 h.p. plant could be reinforced to give 10,000 lights, and that without the enormous waste of 966 heat units per pound of water. Water power could be used to generate electricity, and coal then used to reinforce the output and double the power, by using an Acheson thermo-dynamic generator. The idea is certainly novel, and sounds rather like a Yankee joke. Several of their "jokes" have, however, before now turned out to be facts, but whether this one will have any real practical outcome we cannot, of course, say, without a good many further particulars.

Passenger Telpher Lines.—We understand that the United Electrical Engineering Company, Limited, have just closed a contract with the Mines and General Telpher Company, Limited, for the equipment of a telpher line to convey visitors from the Wood Green Station up the hill to the Alexandra Palace. The Palace seems to have entered upon a prosperous era, and it is confidently anticipated that the coming season will be a specially successful one. The Wood Green entrance is that by which a very large proportion of the visitors enter the grounds, and the line is for the purpose of conveying them from thence to the Palace and back. The simplicity and economy of electrical traction is likely to cause very great extensions in the equipment of light railways and tramway lines between towns and outlying suburbs and villages which are not yet provided with carrying accommodation, and the great practical development of telpherage, initiated by the Palace line, will doubtless command for the system a very great deal of attention. Even in the United Kingdom, where transport requirements may be said to be much better provided for than in other countries, a considerable amount remains to be done. A glance at the maps of either of the three kingdoms will show that large tracts of

Digitized by Google

productive country are unprovided for, so that producers and the travelling public are placed at a considerable disadvantage in competing with those who are more fortunately situated. As has been pointed out by Mr. A. R. Bennett in respect to Scotland, it would certainly not pay to open up most of these districts by means of the ordinary steam railway, even if single tracks and light engines were adopted; but they might profitably be exploited by means of telpher lines or electric tramways laid either on the public roads or close beside them. In the case of the colonies and abroad, of course, the field is enormous, and it would seem that the telpher system may be a powerful factor in leading to the development of countries which either do not possess capital enough to build railways or even to make common roads, or have not sufficient traffic to justify a large expenditure.

London Central Subway.—This Bill came before a Select Committee of the House of Commons on May 9. It proposes the construction of an electrical subway railway between Holborn circus and Piccadilly, with stations at St. James's-street (Piccadilly), Piccadilly-circus, Cambridge-circus, the British Museum, Chancery-lane, and Holborn-circus. The London County Council, the City Commissioners of Sewers, the Strand District and the St. Giles's District Boards of Works, and owners and occupiers opposed the Bill; the *locus standi* of the Metropolitan and the Metropolitan District Railway Companies having been disallowed. Mr. Littler, Q.C., said that the resonance feared from the large quantity of metal used in the construction of the subway would be removed by the use of a material known as fer-flax, composed of iron and vegetable fibre shreds, which would be compressed and packed as panelling between the metal pillars of the subway. At the majority of the stations the public would only have to descend 12ft., or about 20 steps. Galleries would be provided for pipes and wires, which would remove the danger of overhead wires, and also the inconvenience of taking up streets to repair pipes. The carriages would be long cars on the American or tramcar system, each holding about 50 passengers, and would form almost a piston in the tunnel, each car being provided with safety wheels, on to which it would simply drop if an axle broke. A system of deflecting plates would keep a derailed train going along until stopped by the brakes, which would be magneto-electric—the quickest and most powerful known. The trains would run every two minutes, and at a greater speed than on the underground railways. The fares would be from end to end, 2d. first-class, and 1d. third. The inventor would be paid no cash for his patent, but there were 500 founders' shares of £1 each, which would receive one-half of the surplus profits after 5 per cent. had been paid to the ordinary shareholders on the capital of £750,000. Contractors were prepared to construct the subway for £350,000. Colonel Hazard, one of the promoters, was examined, and the committee adjourned. The Bill was further considered before the House of Commons Select Committee on Monday last. Evidence for the promoters was continued, Mr. Harrison Hayter, C.E., in the course of his examination, stating that the width of each train would be 8ft. 2in., the cars being of a size to give 6in. clearance on each side and above, and, acting thus as a piston, would insure ventilation without the blowholes to which objection had been raised in the underground railways. At the terminal stations he thought that the best plan would be for the two lines to converge into one, there being no locomotive to change, the passengers alighting on one side and the fresh ones entering on the other. He was of opinion that the subway could be constructed well within the estimates. Mr. Chatterton, a surveyor, was examined as to the practicability of dealing with the various underground gas and sewer pipes. The committee again adjourned.

The Thomson Meter.—Prof. Elihu Thomson has introduced an interesting modification into the present form of his oscillating electric meter, described by us in our issue of March 22, 1889. In the new form, the liquid is not transformed bodily from one bulb to the other bulb, but passes over in the form of vapour, which condenses, and thus finally overbalances the weight of the bulb which, for the time being, is being heated by the current. In the first form, the effect produced is an effect which is as the square of the current in the coil, for the reason that the heating effect is as the square of the current, and is proportional to the time of flow. The effect which one wishes to obtain in the case of a meter is, however, one proportional not to the square of the current, but directly to the current itself which is to be measured, and the object of Prof. Thomson's modification of his meter is to correct this effect, and to produce a registry in direct proportion to the current flowing on a lamp or power circuit. He does this by passing currents through the meter in direct proportion to the square roots of the currents in the circuit of the lamps, so that no matter how many lamps be in use, a correct record is shown. In the case of alternating currents a fair approximation is obtained by supplying the meter from the secondary of a small transformer, whose primary connects with the circuit carrying the current, the same as, or proportionate to, the current to be measured; and by arranging the coils of the transformer so that their inductive relation changes by reason of their mutual reaction. In one arrangement of this kind a double fixed coil is placed in a circuit with the lamps; mounted on a vertically pivoted shaft is a second coil, delicately poised, whose terminals are carried through to the heating coils. The second coil is, however, capable of rotation on its vertical axis, and, to avoid friction, its terminals dip into vertical cups filled with mercury, from which connection is made. A delicate spring, adjustable as to its fixed extremity, both in position and elasticity, is attached to an arm extending from the coil or its supporting axis. The spring, which is wound conically, and is of very light wire, is adjusted to pull in such direction, and its elastic force is made such, that alternating currents on the first coil will, when the second coil is circuited through the heating coil or resistance, cause deflection from the second coil to a position at which its plane approaches a right angle with that of the fixed coils. At the same time, the current induced in the movable coil by those in the fixed coils is as the square roots of the currents in the fixed coils. By suitable restraining influences governing the motion of the movable coil under the deflective actions exerted, a fair approximation is obtained to the conditions required. The idea is, in fact, to so adjust the parts in their relations of size and effect that the current induced in the movable coil by currents on the fixed coils shall always be in proportion to the square roots of the currents of the latter. Prof. Thomson has also applied the method to the direct registration of continuous currents, but this application does not seem to have proved so satisfactory as that we have just described for alternating currents.

SANDWELL'S ACCUMULATOR TRAMCAR AND TENDER.

Experiments have been going on for some little time in a quiet way at Holloway, with an arrangement for running electric cars with the accumulators on a separate trolley or tender, the tender being hooked on in front or behind the car itself, and the motor and gearing only being carried on the car. We have already (on p. 298, vol. ii., Oct. 12, 1888) alluded to this form of electric car, which has been designed and carried out by Mr. W. D. Sandwell, of Victor Engineering Works, Victor-road, Holloway, London, N., near Finsbury Park Station, and we have expressed an opinion that this method of traction may possibly prove to be one of those by which accumulator cars will first be introduced practically on our English tramway lines. It is maintained by the maker that such a system is one which enables electric traction to be introduced upon the ordinary tramways without alteration of the lines, and with the least possible alterations of the present cars, while enabling the storage cells to be manipulated with ease, and without damage by lifting in and out; and at the same time saving the necessity for extra outlay in having, as usually proposed, either very large batteries of accumulators, or else two sets of motors, gearing and fittings, etc., as must be the case with a separate electric engine or locomotive to draw the cars. It is evident that one of three things must be done with the ordinary accumulator cars, or with electric engines: either the cars must be greatly strengthened and altered to carry sufficient cells; or an electric engine must be made large enough to provide energy for the whole day's trips; or else two engines are needed, each with complete motor, gearing, and all fittings. It is to obviate these necessities that the Sandwell car and tender has been introduced, and, at the same time, some special methods of working the cars have been introduced, which we shall place before our readers in this article.

The chief points about Mr. Sandwell's system are, first, the use of the separate trolley or tender, for which he claims an exclusive patent; and, second, the arrangement of two armatures mounted upon one spindle, the field-magnets of which can be shifted mechanically from one armature to the other—either for alteration of power, or, as more especially intended, for a safeguard in ordinary running—the second armature being able to be used after heavy running up hill if the first one has become at all heated, and also as a stand-by in case of a breakdown.

We are not here concerned with the discussion of the advisability of the use of double armatures—a matter that is open to discussion from various points of view—but with the description of this system as now practically proposed. It may be fittingly argued that electrical engineers should be able to make their armatures sufficiently well designed not to heat or to break down at all; but if at present it remains the fact that the armature is the weakest part of the usual systems of electric traction, it may be advisable for electric tramway engineers, if they are so disposed, to take means to obviate this weakness by the provision of double armatures. If this is the case, the device adopted by Mr. Sandwell admits of the ready substitution of one armature for another, by the simple movement of a lever handle on the car platform.

THE TROLLEY AND CAR.

The appearance of the special feature of the Sandwell system is shown in the illustration of the trolley as attached to the car, Fig. 1. A low car on wheels of the same gauge as the tramcar, and suitably painted and finished to correspond, is fitted with shelves for the storage cells, which are permanently connected up on this trolley, and after once fitting do not afterwards require removing. The lid is removable to allow of inspection, and the terminals of the battery are connected to flexible connections which are fixed at a suitable distance apart to a handle, which is constructed to slip into a double spring-catch connection on the car itself. The battery consists of 68 cells of the latest E.P.S. traction type, the available E.M.F. at work being taken as 130 volts on the car. The capacity of the battery is 140 ampere-hours.

The advantages claimed for this method of carrying the cells are that the cells, being permanently fitted and on separate trolleys, are so easily handled that the life should be considerably lengthened through the absence of the necessity for lifting about separately: the saving of labour

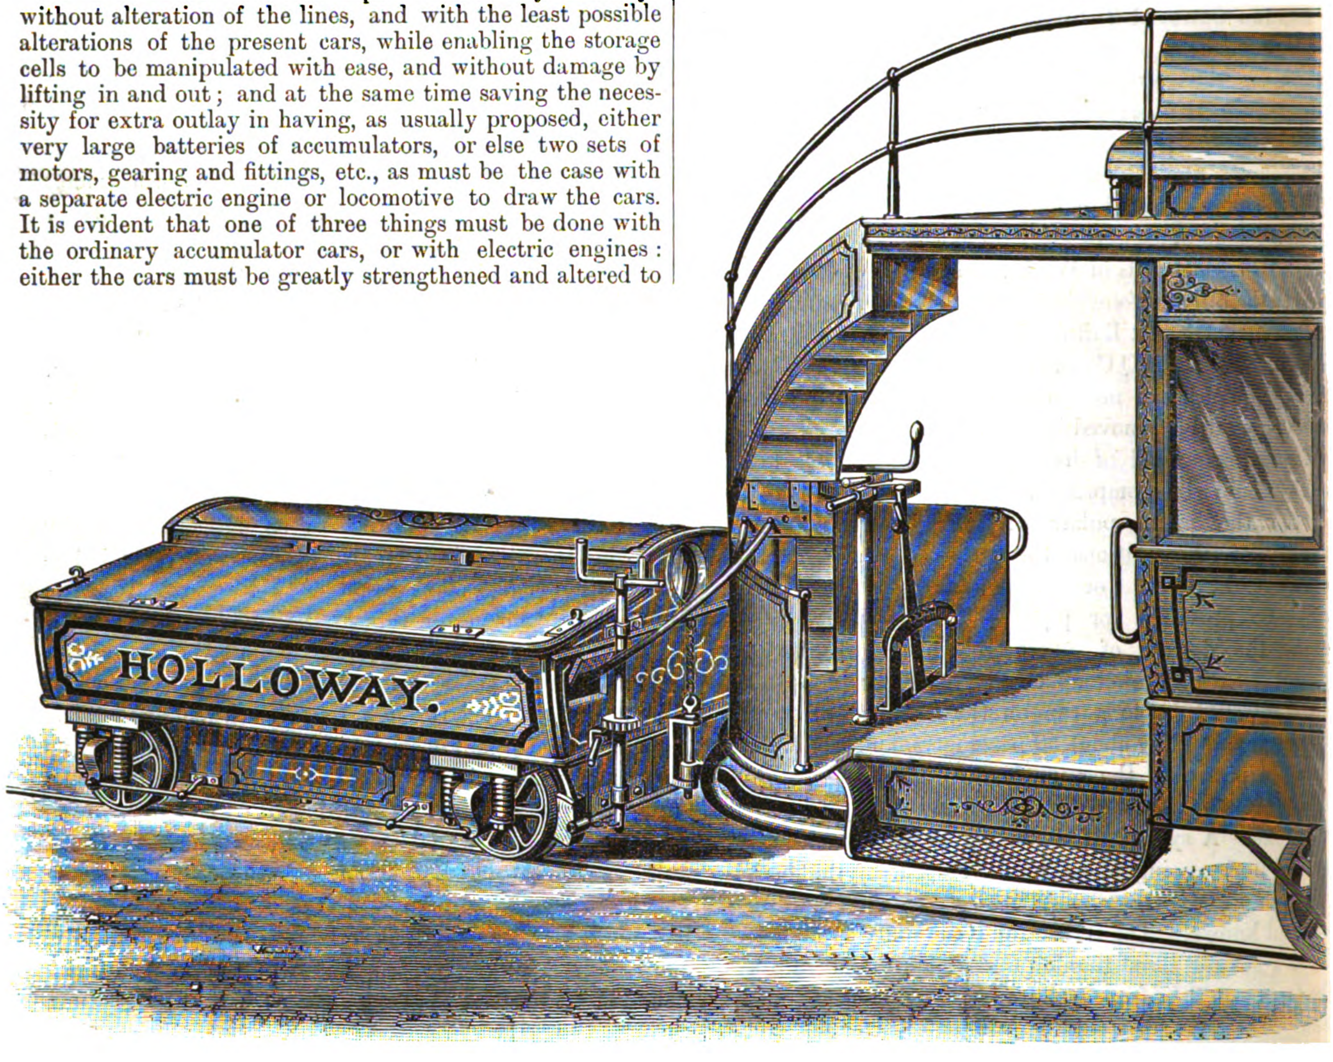

FIG. 1.—Sandwell's Accumulator Trolley and Car.

Digitized by Google

is also a further advantage; while the danger or disagreeableness from acid being in the same car as passengers is entirely obviated, and no disadvantage from the occasional slopping of solution will therefore be noticed. The trolleys can be easily unhitched and run into the charging-shed; a small electric locomotive could, if found necessary, be employed for the shifting of the trolleys on a large system.

The Motor and Gearing.

The car used by Mr. Sandwell is one of the ordinary Moorgate-street trams, which has been lent by the North Metropolitan Tramway Company, the directors of which have considerably interested themselves in the working of their cars by accumulators on this system. The arrangement of motor and gearing is clearly seen in the accompanying perspective view, Fig. 2, which shows the car frame separately. Toothed gearing is used with double speeds, the driving power being communicated by belts. Two toothed wheels of different sizes are fitted to the axle of the car wheels. The motor drives by a belt upon two pulleys fitted to double shafting, the shaft of one pulley being solid, the other hollow, fitting over the solid one in the usual manner of hollow shafting. The shifting of the belt from one pulley to the other effects the alteration of speed as desired. Full details are shown on the plan of the car, Fig. 3, which also indicates the electrical connections to the switchboard and resistances. These connections are the same at both ends of the car.

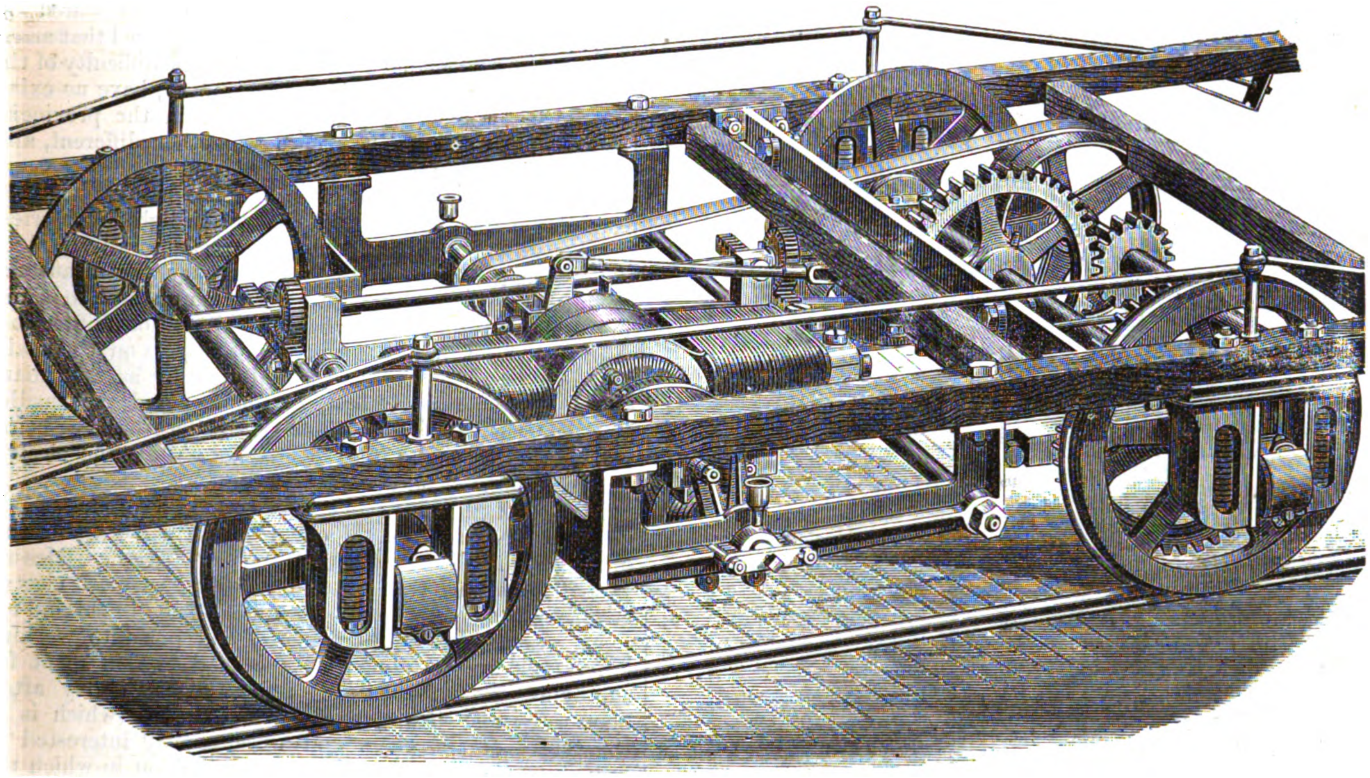

Fig. 2.—Frame of Sandwell's Electric Car—Perspective View.

The motor, which has field-magnets of the Siemens type, and a Gramme armature, has two similar armatures fitted upon one motor shaft. The armature is 12in. diameter by 9½in. long, wound with 580 turns of copper wire ·089in. diameter. The field-magnets are mounted upon a sliding carriage, which can be operated from the driver's platform by a handle, the working of which, by means of suitable levers and wheels shown, slides the field-magnets from one armature to the other, and at the same time shifts the corresponding brushes. A reversing lever also alters the brushes for the purpose of reversing the motion of the car. Mr. Sandwell uses vaseline for lubricating the gearing, and finds it remarkably satisfactory and cleanly, with no possibility of the splashing about of grease.

The usual current for the motor when in work is 35 to 45 amperes; it takes 20 amperes to start on dead level without load, 30 amperes with load. The car, as constructed, will mount with comfort at usual speed an incline of 1 in 30, and it can be made to mount 1 in 20 if necessary. For any very heavy incline such as occurs at Highgate Hill—a difficult combination of line to work profitably—it is proposed as the preferable method to have the storage station at the bottom, to work the whole of the line with the exception of the hill, by storage cells, and to have a conduit system for the steep part, disconnecting the trolleys at the bottom, and thus only necessitating the costly construction of a conduit line of a few hundred yards for the very steep part, at the same time not attempting to haul the weight of the accumulators up the incline.

The following tests of the motor have been taken with a Prony brake:

Test of Motor.

Speed.	Volts.	Amperes.	Weight on Lever.	H.P. on Brake.
620	150	45·5	38lb.	7·13
710	,,	45·3	35	7·53
720	,,	52·5	36	7·85
780	,,	46·0	34	8·03
790	,,	46·5	34	8·13
800	,,	46·5	34	8·24

Average h.p. = 7·8183. Electrical h.p. = 9·4604.
Efficiency = 85 per cent.

The weight of the motor and gearing is approximately 15cwt., the car itself 55cwt. A full load of passengers may be taken as about 52cwt. The weight of the battery and trolley is 40cwt. The car will run 24 miles with one trolley freshly charged, and it is proposed to change the trolley twice a day for each car.

Cost.

The items of cost can only be given approximately, but it may be taken that the cost of altering the car is about £25; the cost of the cells £110, two and a half sets being required for each car to allow for changing and repairs; the motor and gearing would be about £180 per car. The cost of running is calculated that it would allow of a contract being taken at 4½d. per car mile for lines with inclines not exceeding 1 in 30, of which the inclines will not exceed 20 per cent. of the whole length. Other easier or more difficult lines at proportionately less or more for the expense of running.

The experimental car and trolley constructed has made several trial trips from Holloway to Moorgate-street and back with satisfaction, and no difficulty is experienced in working the trolleys or the cars. The system is being worked out privately, Mr. Sandwell being backed up by several financial men of high standing to carry out the

Digitized by Google

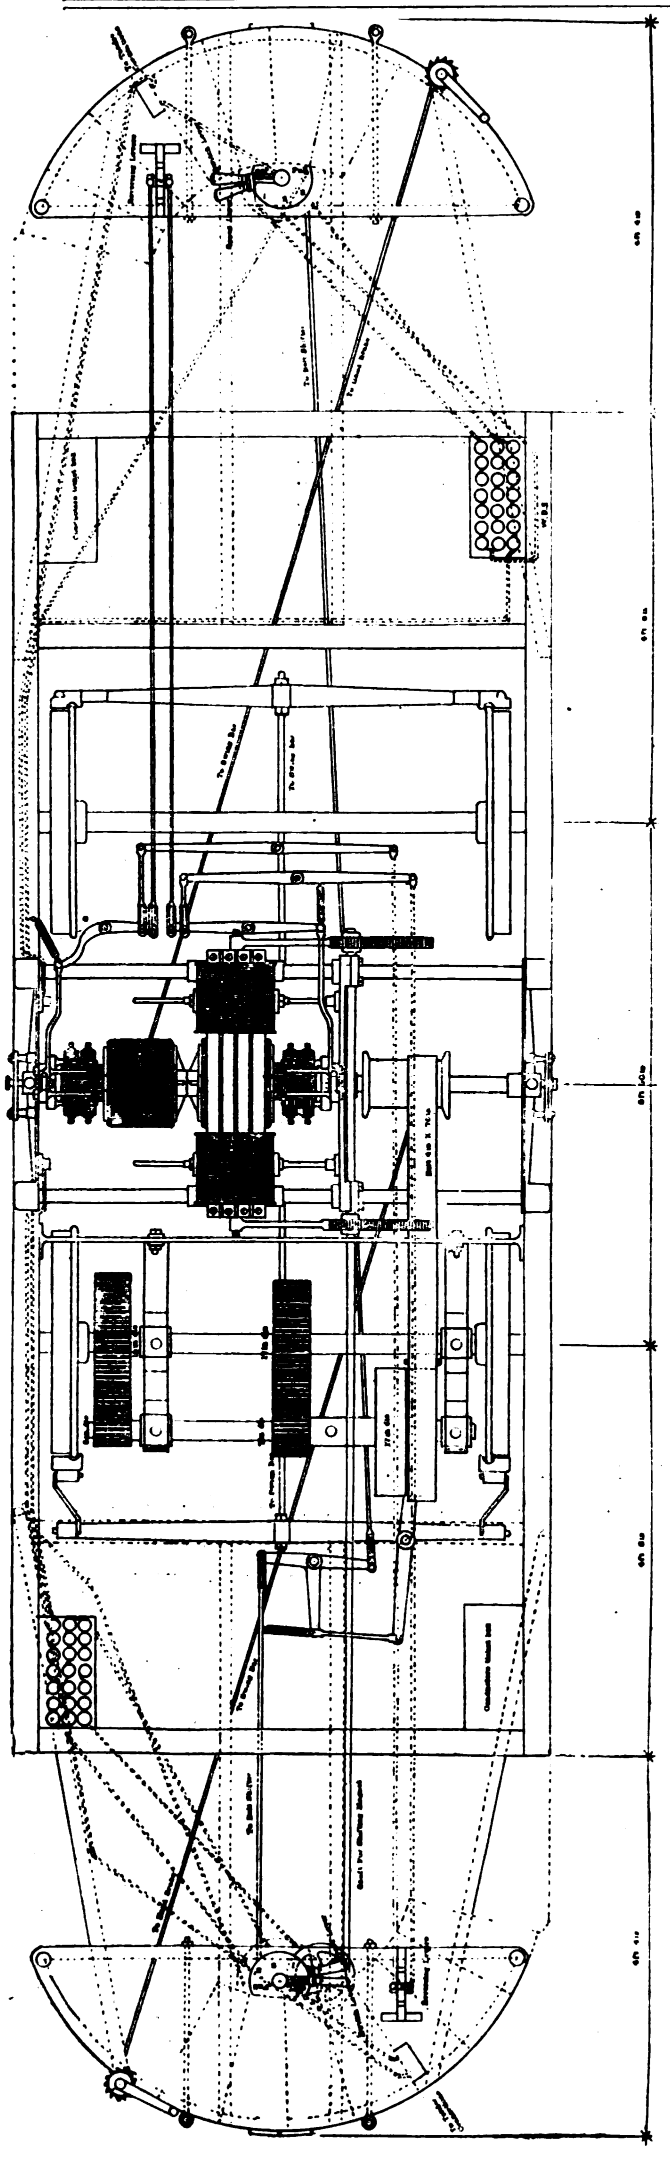

FIG. 3.—Plan of Sandwell's Electric Car, showing Details.

system, the details of which are now perfected, and it is expected to shortly undertake contracts for working existing tram lines on the combined car and accumulator trolley system.

CENTRAL STATION LIGHTING IN GLASGOW.

The electrical world has become so much exercised over the electric lighting of the metropolis, that the very promising field of enterprise in our large provincial towns is still comparatively virgin soil for electrical operations. Great amounts of capital have been placed at the disposal of electrical engineers for the exploiting of the electric light in London, and inventive genius has been busily—and profitably—employed in devising and carrying out a variety of schemes each claiming superiority in economy and in assurance of continuous and reliable working. In our larger provincial towns, however, we do not find amongst the local capitalists even a comparative appreciation of the electrical industries, and the employment of electric energy as a lighting agent for general use is to them an unknown thing. It may be that the troubles which have arisen, and which have militated so grievously against the extension of central stations in London, have scared off provincial capitalists; but it must be remembered that many of the factors which have contributed to the difficulty of the problem as it is presented in the metropolis, have no existence in the problem as it is presented in the provincial towns. There the conditions are altogether different, and the problem very much easier of solution.

In and about our large towns there are many admirable examples of the application of the electric light in factories, warehouses, and mansions, but there is urgently wanted, at these centres of population and industry, the means for placing the electric light within the reach of those to whom an "isolated plant" is impossible, by reason of its first cost or of their local circumstances. Shopkeepers on the main thoroughfares who use ornamental lighting as a brilliant and effective advertisement, warehouses and the smaller manufactories whose business necessitates their being situated near the business centres—to these the electric light should be at once available.

In view of the foregoing remarks, we have pleasure in directing the attention of our readers to a step in this direction which has now been taken in Glasgow. Messrs. Muir, Mavor, and Coulson, Limited, whose name as electric engineers has been well known in the West of Scotland for some years, have just completed and put into working order their first instalment of a central station plant for supplying electric light to the public. On Monday afternoon we visited their electric lighting station (which is in the centre of the city), and were greatly interested in examining the thorough workmanlike fashion in which the whole arrangements have been carried out. They have adopted the alternate-current transformer system and use the Ferranti dynamo and transformer. Although they have at present only one large machine, driven through rope belting by a 200 h.p. compound engine, they are not quite in the risky position of having all the eggs in one basket. A smaller dynamo driven by a 50 h.p. engine is available for day work and contingencies. They are thus able to accept customers to the extent of 3,000 to 4,000 8 c.p. lamps, but the preliminary arrangements are already completed for doubling or trebling that output. Indeed we understand that the existing plant will be doubled in the course of the next few months.

The price at which the electric energy is offered to the public is 8d. per 1,000 watt-hours, with a sliding scale of discounts according to the annual quantity consumed. Amongst others the city authorities have become customers to the extent of 1,100 16-c.p. lamps for the new municipal buildings in George-square.

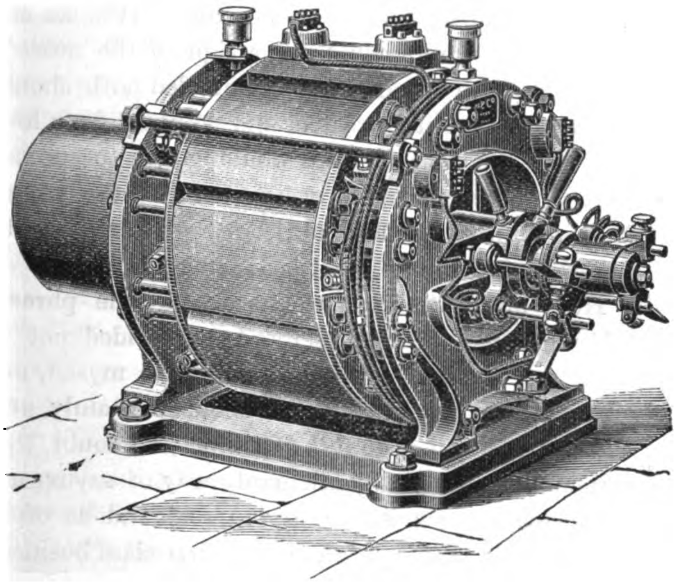
We wish Messrs. Muir, Mavor, and Coulson every success in their new venture, and hope soon to hear that their plant is fully occupied. In conclusion, we again urge capitalists in our provincial towns to turn their attention to this outlet for capital. They will, we are assured, find in their own towns electricians who are willing, and as able

Digitized by Google

as they are willing, to employ that capital wisely and profitably in placing at the command of public consumers the great advantages of electric energy, as an agent for effective illumination and for the transmission of power. If local capitalists do their duty by this enterprise, the public will ere long be constrained to rise up and call them benefactors, and their banker's balance will be an increasingly pleasant consideration for their leisure hours.

THE GANZ ALTERNATE CURRENT MOTOR.

We are able this week to present to our readers a woodcut, reproduced from a photograph, of Ganz's alternate-current motor, reports of which of such favourable nature have been recently forwarded from Buda-Pesth. We have here, for the first time, according to the information received, an alternate-current motor, working up to 30 h.p., and giving a commercial efficiency of over 80 per cent. Such particulars as are received are given on the authority of Messrs. Zipernowski, Deri, and Blathy, the well-known electricians to the firm of Ganz and Co., and this firm, whose status as an engineering firm is beyond dispute, and whose practice on the installation of alternate-current plant is probably larger than any in Europe, now definitely announce that they consider the problem of the production of a really practical and efficient motor for use on alternate-current circuits completely and satisfactorily solved.



The Ganz Alternate-Current Motor.

Details of the construction and winding of this motor have yet to come, but in the memorandum which Messrs. Ganz have sent us accompanying the photograph, it is stated that the tests shown in the table we have already given were obtained with a model motor, the outcome of experiments extending over a period of four years. This model, although extremely satisfactory, does not itself show the highest efficiency to be attained, but has yielded results which give the clue to show what are the best methods of construction, and from calculations made they confidently anticipate the working motors will give an efficiency of over 90 per cent. in actual use. An important point, remarked upon by the inventors, is that whereas in the former attempts to construct alternate-current motors the *apparent* energy absorbed measured on the voltmeter and ammeter, and the *actual* energy absorbed measured on the wattmeter, were widely different, due to the employment of the alternating current. For instance, a motor taking 5,000 watts on a 100-volt circuit would show an apparent absorption measured in the ampere-meter of—not 50 amperes, as would be the case with continuous-current motors—but 100, or even 150 amperes. Motors on this model, therefore, even of a partially practicable efficiency, would necessitate leads and generators of greater size, such as would be impossible to employ on central station work solely for the distribution of power. In the motor shown, the apparent and the actual energy absorbed closely approximate, being in the experiments given 29,800 measured in *volt-amperes*, and 27,700 measured in *watts* respectively, the energy returned being 22,400 watts, thus showing a commercial efficiency of 80·9 per cent.

The objections to the types of alternate-current motors hitherto constructed may be thus stated: (1) their efficiency was far below that of continuous-current motors; (2) most types were unable to control the speed, so that the motor, even if it could be got to work at all, was useless practically on account of the speed varying most erratically as the load was altered; (3) that three or more conductors were needed for the supply of current; special types of dynamos were also required; or two dynamos of the ordinary type were necessitated to be coupled in a certain phase. How far Prof. Ferrari and Mr. Tesla, who have done most work at these problems, have overcome the difficulties has not yet transpired. The electricians of Ganz and Co. have pursued their work in other directions, and have produced a motor which they state can be thoroughly controlled in speed; can be worked on ordinary alternate-current circuits with ordinary lead and return wires; is very efficient, and with which they are perfectly satisfied.

Beyond the fact that the extension of alternate-current systems itself renders desirable the production of an efficient alternate current motor, Messrs. Zipernowski, Deri, and Blathy point out that this class of motor has distinct advantages over the ordinary class of continuous-current machines.

First, that it is easy and certain of regulation for constant speed at all variations of load within its working limit.

Secondly, as the high-tension current has not to go through any commutator, as in continuous-current motors, a higher E.M.F. can be safely used for these motors, with corresponding economy of transmission, as the conductors can be soldered directly to the terminals.

Thirdly: This fact, and the fact that the armature is fixed, allowing the employment of a higher potential, allows the network of mains for motive power to extend over a far greater area, and produce a correspondingly better service of power distribution.

Fourthly, for direct transmission of power, from waterfalls or other sources, it will allow for the employment of current at a potential impossible to work with continuous-current motors, and thus extend to far greater limits the economical employment of power from sources at a distance, which now run to waste.

Fifthly, that with continuous-current motors there is a limit below which it is impossible to construct really efficient motors for small powers, a fact that much militates against their extended use for household or business purposes, as distinct from manufacturing purposes, in central installations. On the other hand, with an alternating system it is possible to transform any current economically and without loss, rendering the smaller sizes of alternate-current motors far more economical than is at all possible with continuous-current motors, rendering their introduction into private houses for all purposes a practical possibility.

And lastly, with alternate-current motors there is no need of resistances to be inserted in the circuit at starting, the self-induction of the motor taking the place of resistance, and this fact again greatly simplifies the installation of motors. The construction of a good practical alternate-current motor is in reality the true solution of that most most important problem, the economical distribution of power from central stations.

But the most important item is that Messrs. Ganz are already busily at work installing their motors for practical work. At a paper mill near Innspruck a 50 h.p. Ganz alternate current motor will be used to drive the machiery, the motor being supplied from a 500 volt alternating machine, driven by a turbine at 1,000 metres distance. At Weiner-Neustadt two motors of 10 and 5 h.p. will supply a brewery with power from the distance of 2,000 metres. The power here is also obtained from a turbine driving a 2,000 volt alternator, which is also to be used for lighting the station by means of transformers, the first instance on record of the publc supply of light and power from an alternating-current station.

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

FAITH.

It is not our intention to write a stirring story about a woman of this name, or to preach a sermon upon the scriptural definition of the term, though it may, perhaps, be in our minds to follow the example of Addison and Steele, and to drag in a moral somewhere. The time to get in a moral is opportune. There is nothing of overwhelming importance to comment upon just at present, though much might be said of the everlasting persistence of exhibitions. The text of our article flashed into our minds after the remark of a gentleman with whom we were conversing. "There goes," he said, pointing to a passer-by, "a man who ought to be proud of the unique position he has filled, as the boss of a company with a fairly large capital, who never managed to secure one bonâ fide commercial order during the time the company existed or while the money of the company lasted." How many would jump for joy to be put into such a position—the position, we mean, of manager—with plenty of funds, and the unlimited faith of shareholders and co-directors. It is, as our American brethren would say, a sign of the cussedness of human nature that unbounded faith should be placed where it is wasted, and withheld from him who has the capacity, and would go on to success were he not thwarted at every turn by those whose faith is limited, like the politicians' greatest good, to the greatest number—that being number one.

How often we hear of Jorkins in the phrase, "My partners or my directors have decided not to do this or do that, although, if left to myself, unfettered and untrammelled, I should certainly, and without hesitation, do it." Ofttimes, no doubt, this statement is only a gentlemanly way of saying no, but in many cases it is only too real, and as often detrimental to rapid progress. A first-class business man, be he manager of a small or a large company, must be tolerably conceited; the danger is in being excessively so. He must thoroughly believe in himself, and, by so doing, impress others with a belief in his ability. The failure of many companies has been due entirely to the distrust of every man for his fellows, and here again comes into play the blunderheadedness of shareholders who are apt to think that they, with a modicum of information, know better how the machine should be worked than the directors, who are familiar with every detail. Hence, usually, the shareholders are little consulted. They are told certain things have been done, certain things will be done, certain results obtained, and certain results expected, to give a vote of thanks, take their dividends, and pass out. They are asked for unlimited faith, and usually give it, when a concern is newly floated, or when it is fairly prosperous. Our remarks do not apply to other cases. If any real attempt is made to take shareholders into confidence, it leads to a row, and some-

Digitized by Google

times to a change of directors, because it is impossible to enter fully into the business details which lead the directors to certain conclusions, and the half explanation which is given, as we say, leads to something different to what the directors desire. Success means full faith of shareholders in directors, full faith of directors in their managers.

Another direction in which huge demands are made upon our "faith" is as to any good arising from investigations into electric lighting matters. Many of the opinions expressed in the report of 1879, that is only ten years ago, might, for all the value they are, have been expressed in the time of Noah. We find now, as was found then, that the men who come forward, or who are paid to come forward, speak with considerable emphasis, but a year's or a couple of years' further experience is just as likely to prove them utterly wrong as right. Prof. Tyndall in the 1879 report, says "We are advancing towards perfection, whether we shall ever obtain it or not is another question." It seems that many people in the witness-box forget the possibility of further advance. Because this or that has not been done, or because they have failed to do it, is no proof that further advance will not show the work to be comparatively easy and simple. Various witnesses frequently in these investigations contradict each other point-blank, and hitherto the evidence has been ancient history before it was printed *in extenso.* The value of these investigations is to let rival organisations cut at one another's throats by causing the expenditure of huge sums of money unproductively. Pin your faith on the Board of Trade is the present cry. Well, we think the Board of Trade had better let local authorities settle their own affairs, whether those affairs concern electric lighting or the erection of a town pump. If the local people like to have overhead wires, what has the Board of Trade to do with it? if they insist upon underground, it is purely a local matter. If stirring competition is wanted, let the local authorities give carte blanche; if only a little competition, let them play off one company against a second. Surely each authority and each company is capable of looking after its own affairs and wants no wet nurse in the shape of the Board of Trade. This modern idea of making everything and everybody run in a certain groove by Act of Parliament is utterly subversive to the natural instinct of the Anglo-Saxon race, which tends more to self-reliance. But while the cry is "Home Rule" and decentralisation on the one hand, the action is towards centralisation and grandmotherly coddling on the other. There is still one other reference in this olla podrida to which we would call attention. Too much has been done and is being done in electrical matters that is of a non-paying character. John Bull, in the shape of a shopkeeper or a local board, is apt to say, "Show your own faith in your own wares, put up the light, and if it goes all right we may possibly come to terms and buy it." Now this exhibition of faith has led again and again to disaster. Anxious to show business, the private firm or the company has put down a temporary installation, with the result in a great number of cases that the temporary work has failed again and again, and so have the firms and companies. The public won't understand the difference between temporary and permanent; they don't want to, and we cannot blame them. The falling in with such whims is a sign of weakness on the part of the suppliers of the apparatus. If the temporary work is installed as if it were going to be permanent, all well and good, but it is not. The installers have not enough faith in their own goods or in the bonâ fides of the customer to do this, hence, what is done is done roughly and unsystematically, leading, as we say, to disaster.

CORRESPONDENCE.

PITKIN AND NIBLETT'S FIREDAMP METERS.

To the Editor of The Electrical Engineer.

Sir,—With reference to the firedamp meter which you have so kindly noticed in your leader last week, there can be no doubt that the whole of the questions which you so pertinently ask will have to be satisfactorily answered before we can expect these instruments to be generally adopted by miners.

When the meters were being exhibited at the Royal Society on the 8th inst., and again at the Royal Institution, 10th inst., great diversity of opinion was expressed as to the probable effect of time and repeated usage upon the active materials we employ.

I may say that all the points raised by you are receiving our most careful attention. A series of tests and practical trials are now proceeding, which, I trust, will bring out both the weak and strong points in this form of gas indicator. As time, and time alone, will be the only true test of the durability and active life of the spongy or finely-divided metals, it is somewhat premature to attempt an explanation of the apparent law or general effect of repeated and hard usage upon these substances. As far as our experience goes, no deterioration in the active part of the detectors under observation appears to have occurred. Should we find that a weakening or, as you term it, a tiring of the spongy metals occurs, this difficulty could be readily overcome by periodically renewing the active part. In the present form of these instruments, these renewals would be a very simple matter.

We do not anticipate the slightest danger which might arise due to a possible overheating of the spongy metals. The quantity of these metals employed is very small, and being placed directly on the bulb of the thermometers, the heat developed is rapidly communicated to the comparatively large mass of mercury in the thermometer bulb. Suppose a dangerous heating did occur, we still have the protection afforded by the wire gauze with which we surround the gas chamber. The gauze in this case would act exactly as it does in the Davy lamp. It is well known that the oil flame in the Davy lamp is rendered quite safe when in an explosive mixture, owing to that peculiar power of rapid radiation and diffusion of heat possessed by a fine metallic network. When enclosed within wire gauze, it becomes possible to safely utilise the light emitted by highly incandesced particles of carbon, which partly constitutes an oil flame. Mr. Pitkin proposes to substitute porous earthenware plates for the metal gauze. This arrangement would not interfere in any way with the free action of the gases upon the thermometer

Digitized by Google

bulbs, and we should then avoid all possible danger arising from the overheating which you imagine might occur.

With reference to the advisability of employing an aural as well as a visual indication of the presence of explosive gas in mines, an electric bell attachment is now being fixed to an electric miners' lamp. These alarms will work quite automatically, and may be set to go off at any particular point.

To meet all requirements, instruments of various sensibilities will have to be made. Probably those having a range of from 5 to 15 per cent. would be found the most useful for ordinary coal-mining operations.

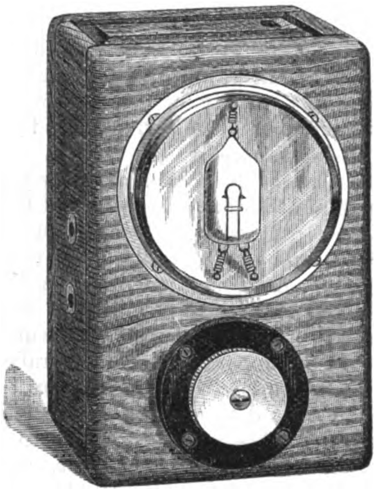
A form of instrument not yet shown, but which, owing to its great sensibility, may perhaps prove the most generally useful, is a two-bulbed differential air thermometer, having a short indicating mercury column. Under ordinary circumstances, and when the surrounding air is free from active gas, the mercury column will stand at a fixed zero at all temperatures. As soon, however, as the balance is destroyed by the unequal heating of the bulbs due to the presence of gas, an immediate displacement of the mercury will be produced. By suitable calibrations it is evident that this form of meter may be pointed off directly in terms of percentages without any correction for changes of initial temperatures.

I trust that I have not encroached too much on your valuable space.—Yours, etc., J. T. Niblett.

May 15, 1889.

THE PITKIN POCKET LAMP.

The Pitkin pocket lamp has been constructed with a view of getting a serviceable electric lamp in a very small and portable form. It has been designed, we believe, primarily for miners' use; but not essentially for this, as a small lamp is very generally useful for various purposes, if it can be carried about—for reading in trains, for astronomical telescopes, microscopes, and other scientific purposes, either combined with the battery or separate; and, with a ruby glass, would be very serviceable to photographers.



The Pitkin Pocket Electric Lamp.

The form of lamp illustrated is useful for any of these purposes where a combined and very portable little lamp is required. The total weight of the lamp is only 1lb. 13oz. complete, probably the smallest practical self-contained accumulator lamp yet made. The lamp is a 4-volt incandescent lamp, with bulb made of a flat shape to fit inside the glass reflector, and gives about 1 c.p. The battery is a two-cell secondary Pitkin battery, of five plates each, constructed with small projecting pins on the lead plate. It is contained in a vulcanite cell, which is fitted with polished walnut wood or oak. The charging terminals are two split tube ends, sunk just below the outer wood casing and connected to the terminals of the battery. The charging current is ½ ampere for eight hours. The lamp takes 0·35 ampere, and will burn with satisfactory light for six hours. It has a white or French-silver reflector at the back of the lamp; and the lamp itself is fitted by springs and a hook. The switch is operated by a milled screw-head, and inside has a resistance of 1 ohm, which allows the lamp to be turned on gradually and regulates the strength of the light when the battery is newly charged. The battery illustrated is the one exhibited at Mr. Preece's lecture, and lamps of the same form were exhibited at the Royal Society's conversazione. This kind of lamp has only just been made for sale, and it is a highly serviceable and efficient form of pocket electric lamp. The lamps are made by Mr. J. Pitkin, Red Lion-street, Clerkenwell.

FIREDAMP METER.

We herewith illustrate these ingenious instruments, which were fully described in our last issue. Fig. 1 shows a pattern that can be hung vertically upon any support. The two thermometers are seen, and the bulbs are covered with wire netting. Fig. 2 shows a pattern in the form of a watch, an exceedingly convenient form, as will instantly suggest itself to anyone. The meter will be constructed in other forms, such as the differential, wherein the mercury fills the bends of a U tube, the bulbs being filled with air, the expansion of which in one tube under the influence of the heat generated by the action of the gases and the platinum-black is greater than in the other, thus causing the mercury to stand at different heights. It will be seen from Mr. Niblett's letter that there is something to

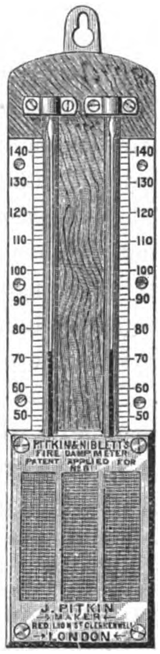


Fig. 1.

Fig. 2.

be said on the other side of the questions raised by us in our last issue. For the sake of the biggest and most important industry in the world, we trust that this instrument can be perfected.

ELEVEN YEARS ELECTRICAL PROGRESS IN CHELSEA.

The rapid progress of electric lighting is perhaps most clearly shown when we mark its course in one particular area; and as it is now about eleven years since the subject first received the attention of local authorities, it may be well to glance at the district of Chelsea to see what progress has been made there, especially as that district has always been to the fore in striving to place electric lighting on a sound basis as regards control by the local authority.

The desire for electric lighting in Chelsea was not an outcome of the electric lighting mania of 1882, but dates to some four years previous, when a letter was addressed to the Vestry calling its attention to a system of lighting

Digitized by Google

gas lamps by electricity then in use in Pall-mall. This set the ball rolling. Attention was called to the unsatisfactory condition of street lighting in London generally, and the Chelsea surveyor was authorised to go to Paris to examine and report on the system of electric lighting in use there. Very little was known about electricity to the general public in London at that time. It was looked upon as a mysterious force, and the mystery was still further heightened by the erratic arc lamps which used to fizz and sparkle outside the Gaiety, and which were looked upon as one of the gazing-stocks of town.

The surveyor went to Paris, interviewed M. Jablochkoff and others, and reported that to light Sloane-street (1,100 yards long and 20 wide) by the same system as in use in the Avenue de l'Opera would necessitate two electric stations, each with a 16 h.p. engine, and the cost would be about £3,200, and the 32 electric candles required to light this area would cost 16s. per hour. The light would have been 31 times greater than gas. Naturally, such a system could not be recommended for ordinary street lighting when one engine would be required for every 16 lamps, so the matter was allowed to rest for a short time.

During the year 1878-9 an attempt was made to have a trial of electric lighting in and near Sloane-square, but as no definite or reasonable terms could be obtained the question still stood over.

During 1880-81 no negotiations were entered into, but the progress of electric lighting in the City was closely watched, and the result was quite as valuable to the parish as though a large expenditure had been incurred. In the year 1881-2 negotiations were opened with a firm who *thought* that they could light the neighbourhood of Sloane-square for £612 under the Brush system, but as gas cost less than £400 no further action was then taken. During the summer of 1881 the Electrical Exhibition at the Crystal Palace was visited and results noted. Towards autumn, however, the air began to be charged with electricity. An Electric Lighting Act was spoken of as certain next session. As a natural result many private Bills were talked of, and some few were considered by the Vestry, and the Board of Trade was communicated with. As neither the Electric Lighting Bill nor the private Bills provided for the submission of plans to the local authorities, the Board of Trade was appealed to, and a list of suggested amendments to the Electric Lighting Act were forwarded to Parliament. The Electric Lighting Act became law. Immediately, about half-a-dozen companies applied to light Chelsea. The Vestry, having decided not to apply for a license or provisional order themselves, agreed to support any company who would carry out the work upon condition of which the Board would approve. To discern the merits of the various companies was the next task. To do this the idea of giving each company an examination paper consisting of a series of questions was carried out. The answers obtained were instructive. Some would use 10 c.p. lamps, some 40, some 100. Some would use arcs of 2,000 c.p., and some 3,000 to 6,000 c.p. Some thought one central station would do, while others knew it would not, but one and all declined to give a reliable estimate.

The Brush Company then submitted a draft order. It was amended and reamended, and subsequently became the model for all orders before the Board of Trade. The company, however, did not proceed with it, and in July it was revoked.

In June, 1884, Colchester was said to be basking in the light of electricity, and thither the surveyor was despatched to investigate and report. This was found to be only a system of private lighting, and storage batteries were mostly used. In December, the draft of a new order was received, and after the authorities had been put to great trouble to amend it, it was abandoned when before the Board of Trade, the 21 years' purchase clause being the rock on which it foundered. In November, 1885, the Chelsea Electric Lighting Order, 1886, first made its appearance, and in September, 1886, was confirmed by Parliament.

After this there was a pause, and while the company who had obtained the order were doing nothing, a rival company commenced to put up overhead wires and to give light.

The science of electric lighting was now something to be relied upon, so in 1887 the Vestry did not hesitate to allow the second company to enter into an agreement on very much the same terms as the company who obtained Parliamentary sanction, and have repeated the same course during 1888 to another company.

There are, therefore, now three companies supplying electric light in Chelsea, and all three are under the control of the local authority. There is a feeling among the ratepayers that their interest will be looked after, and a feeling among the companies that they will be treated with perfect fairness.

In conclusion, electric lighting in Chelsea is now an accomplished fact. Two out of the three companies have central stations in the parish. Companies' scrambles and squabbles have been put down with a firm hand, and neither the public interests nor the interests of a genuine company which desires to do a fair business, will suffer in the long run. But it has taken years of hard work.

ON LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS.*

BY DR. OLIVER LODGE, F.R.S., MEMBER.

(*Continued from page 381.*)

Instructive Extracts from Reports of Damage by Lightning.

40. Reading between the lines of existing reports on damage done, one can frequently find evidence of many of the phenomena to which I have now called attention. Of course, they are not recorded in any prominent manner, because they are to the observers ill-understood and puzzling facts: it is very difficult to note what has exactly happened in any given case unless some clue or expectation has been formed beforehand. The bad conductivity clue, which was the only one prominently available to the skilled recorders in the following cases, is a very partial one, and in many cases is quite insufficient to account for the facts without undue pressure being put upon it. Under such circumstances the record of the facts is, of course, far more valuable than the comments made upon that record; and in the following extracts the theoretical remarks should be eliminated or slurred over. One minor imperfection, common to many accounts, is that they are not sufficiently alive to the possibility of all manner of branching discharges; so that the discharge is said to leave a conductor and go to something else, when the truer statement would be that some *portion* of it branched off at such and such a point.

In the following quotations the references are usually to the pages of the volume of the Lightning Rod Conference, published by Spon in 1882:

41. Illustrating side flashes and surging circuits.

"*L.R.C.*, p. 39.—*J. Murgatroyd, St. Mary's, Crumpsall, near Manchester.*—A lightning-conductor from spire touched the eaves gutter, and a gaspipe touched the end of this gutter. The lightning passed from the conductor along the gutter to the gaspipe, melted it, and set the church on fire by igniting the gas."

"*L.R.C.*, p. 39.—*Wyatt Papworth.*—Tall spire struck. The church stands in an open position, with no large trees near. It was provided with an iron lightning-conductor ¾in. diam., fixed with iron holdfasts, and carried down inside the spire and tower into ground. The top of it was said to be attached to a bold copper finial on the spire about 150ft. from the ground, and 50ft. above ridge of roof. The lightning is supposed to have first struck the finial. It slightly deranged some beds of masonry in upper part of spire, then descended by iron rod to belfry, melted a gastube in the floor, and set fire to the belfry by igniting the gas."

From Abstract of Report on the Destruction by Lightning of a Gunpowder Store at Bruntcliffe, Yorkshire. By Major V. D. Majendie, R.A. (L.R.C., p. 77.) "The gunpowder exploded at 4.30 p.m. on August 6, 1878, during the greatest intensity of a violent thunderstorm. The building was brick, with brick arched roof, length 9ft., width 5ft., height 6ft. (internal dimensions). The store had a uniform thickness of three bricks, and was furnished at one end with an iron door, at the other end with a lightning-conductor. The conductor consisted of a copper wire rope, 10 gauge copper wire, the rope being $\frac{7}{16}$in. thick, having four points at the top (one large one in the centre, and three smaller ones round it); it extended to about 13ft. above the top of the building, and about the same length was carried into the ground and terminated in a drain. The conductor had been erected in 1876 by Mr. John Bisby, of Leeds, and was fixed to a

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

pole distant about 2in. from the end of the building opposite to that in which the iron door was fixed (it was not connected with the iron door in any way). No one was near the store when the powder exploded, and it seems probable that [the earth connection of the conductor was bad, that] the mass of iron in the door offered at least an equally good path—and that the gunpowder was ignited by a flash passing between the two imperfect conductors." To make this report more completely scientific, it would be well to omit the words I have put in square brackets.

Extract from a reply of Mr. Baldwin Latham, C.E.—"It is no uncommon thing for buildings provided with what are called lightning-conductors to be damaged by lightning, and the cause is due to the inadequacy of the conductor to carry the electric fluid, which will leave the conductor for a better or a larger conductor." (See also sec. 43.)

42. As illustrating that a good conductor affords no absolute security, the following document is worthy of reproduction in full, as given in *L.R.C.*, p. 115 :

"*Ueber Blitzableiter und Blitzschläge in Gebäude welch mit Blitzableitern versehen waren. Von G. Karsten. Keil.* 8vo., 1887. (*Abstracted by R. Van der Broek.*) In this pamphlet Dr. Karsten gives an account of two cases in which buildings that were provided with lightning-conductors were damaged by lightning. The author states that the statistics for the year 1873 show that in Schleswig-Holstein 26 per cent. of all the cases of fire were caused by lightning ; $\frac{1}{10}$ part of these cases occurred in the towns, and the remainder in the country. Do lightning-conductors guarantee absolute protection ? The author answers this question as follows : There is no absolute certainty in empirical matters. Each new case may direct our attention to circumstances that had been overlooked. If lightning-conductors cannot be said to ensure perfect safety, they certainly afford a very high degree of protection. The flash of lightning which struck the church at Garding on May 18, 1877, fractured the conductor in fifteen places, and pierced the wall of the steeple in two places. The inefficiency of the conductor resulted from the carelessness with which it was fixed ; the line was laid down the north side of the steeple and fastened with 25 wall eyes. These wall eyes were hammered too deep into the wall, thus damaging the line and forming a short and sharp bend in each case, besides also unduly straining the wire. The damage to the steeple was the consequence of a neglected secondary circuit. There are an excessively large number of tie-rods in the steeple ; the heads of these rods are not connected together, neither are they, except in one case, in close proximity to any of the larger masses of metal that are about the building. The conductor passed close to one of those heads. The south side of the steeple, where the opposite head is, becoming wet through the rain, a secondary circuit was formed, and a return shock followed ; the damage to the steeple was trifling. The rod was provided with a conical point, rather blunt, but surmounted by a short platinum point. The copper line-wire was of good material—not of a uniform thickness, but at the weakest places not weighing less than 240 grammes per lineal metre (8oz. per yard, or rather less than ¼in. diameter if solid). The earth-plate was sunk into a well 10 metres deep, and tested faultless after the discharge."

43. The following series of notes are better not separated, though they bear upon different points :

L.R.C., p. 93, *et seq.*—*From Abstract of Statistics of Buildings and Ships struck by Lightning. By F. Duprez, Member of the Academy.*

Illustrating occult dangers from secondary disturbances in the neighbourhood of conductors.—"The author cites three cases of buildings set on fire, though protected by lightning-rods. But the precise cause of the fire was not ascertained."

Illustrating multiple flashes.—"In each of two cases the lightning struck at once the three rods fixed to a building."

Illustrating that a poor earth is not necessarily fatal to the efficiency of the conductor, except as to the protection of the soil itself and of things buried in it.—"Out of fifteen cases of lightning-rods struck, in which the conductors were simply buried more or less in the soil, they carried off the strokes in eleven without the buildings being injured or any trace being left of it, except that the ground was upheaved where the latter was too dry."

Illustrating a matter important, if true : suggested by Prof. Fitzgerald theoretically at Bath : not yet verified by me.—"In two cases the stroke broke the conductor at points where its direction was abruptly changed."

Illustrating side-flash.—"In two other cases the lightning left the conductor struck, and fell upon buildings near, without causing damage to those on which the rods were fixed."

Illustrating brush discharge from conductor, and surging circuits its neighbourhood.—"Two electrical phenomena are to be noted as sometimes occurring when a lightning-rod is struck. First, when a conductor is formed of metallic plates, a peculiar noise is heard, like water pouring on a fire. Second (independently of the form of the conductor), electric sparks are emitted from bodies near. The author cites examples at Berne, 1815."

44. The following illustrate the carrying power of fairly thin wire, and the fact that thin wires may protect although themselves deflagrated. *From Mr. Preece's paper on "Lightning" to Society of Telegraph Engineers, November,* 1872 (*L.R.C.*, p. 101) : "There were only two cases in the past season where line wires (No. 8 iron 0·17in. diam.) were absolutely fused."

From letter by Admiral Sullivan (*L.R.C.*, p. 195): "You will like to know a case in which a copper wire acted as a perfect conductor, *though fused throughout its length.* It was at Monte Video, in the house of the English Consul. A flagstaff was struck, and conducted the lightning through a flat roof near the bell wire of a suite of rooms (the wire ran in sight near the cornice), through a hole in each dividing wall, and then down to the bell in the basement. The wire was melted into drops like shot, which burnt a row of small holes in the carpet of each room. A dark mark on the cornice above showed where the wire had been. At the bell there was a slight explosion and some little damage ; but I do not recollect whether anything acted partially as a conductor from that point, and so carried off that part of the charge. This, I think, shows that even an ordinary bell wire will act as a conductor for a rather strong stroke of lightning, as the large flagstaff was shattered."

45. As illustrating that experience has led to the perception of the value of large surface to a rod, I may quote the standard American work, Spang's "Practical Treatise on Lightning-Conductors." Philadelphia, 1887 (*L.R.C.*, p. 113) : "A conductor of large surface exercises a much greater protective action than the same quality of metal in the form of a wire or solid rod. Not because electricity in motion resides on the surface, but that the expansive action of a discharge may have a wider scope through the metal."

[The incoherence of the reason does not destroy the correctness of the stated fact.]

Messrs. D. Munson and Co., of Indianapolis, Indiana, have sent me specimens of their rods, which have flanges and sharp edges, and in various ways aim at large surface. Their rods are composed of copper and iron mixed, which is curious, and their mode of attainment of large surface is needlessly complex.

The following illustrates the contradictory views about manner of conduction by lightning-rods. *Letter from Admiral Sullivan* (*L.R.C.*, p. 199) : "I firmly believe in the surface theory of Harris. I had been with him often when he made experiments nearly fifty years since, and witnessed a strip of tinfoil of the thinnest kind, and about ¼in. wide, protect a model mast of about 6in. in diameter from electric shock, that without it split the mast to pieces, aided by a small hole through its centre filled with gunpowder. And I always thought that the surface-conducting theory of Harris was indisputable. But about 20 years since, having to approve a proposal of the Trinity House for a new conductor of a lighthouse, which, like previous ones, was an inch in diameter copper rod, called 'Faraday's Plan,' I thought I would go up to the Royal Institution and ask him why he did not use a copper tube instead, giving much greater conducting power with less copper. I did so, and he asserted positively that the conducting power depended entirely on the volume of copper in the section of the conductor, no matter whether it was in a bolt, plates, or tube ; and that if Harris said differently, 'he knows nothing whatever about it.' Of course, I approved the rod conductor ; but singularly enough, though I had not seen Harris for years, he came to town a few days after, and came to the Board of Trade to see me, and bring me piece of his large tube conductor, with a connection, that he was fitting to the Houses of Parliament. When I told him what Faraday's opinion was, he answered, 'Then he knows nothing about it.'"

46. I may call attention to some apparently sound doctrines in a paper by Capt. Bucknill, R.E., abstracted in *L.R.C.*, p. 242. That lightning can penetrate into collieries is proved by an account of a meeting of mining engineers (*L.R.C.*, p. 237). The same sort of thing is illustrated by the accident at Bootham Bar, York (*L.R.C.*, p. 219), when the lightning struck down into a cavity surrounded by high buildings with lead roofs, iron rain-water pipe, and an iron portcullis, to get at a street bracket 11ft. 6in. above the pavement, melting its pipe, and setting a house on fire by the large flame produced (*L.R.C.*, p. 219).

47. That the existence of gaspipes make houses more difficult to protect, and in fact causes dwelling-houses to require almost as much attention as powder magazines, can be illustrated by a good number of extracts. The following may serve (*L.R.C.*, p. 239) : "On July 13, 1880, during a thunderstorm, the large 400-light gasmeter of this mill, though locked up in a cellar, and with no light near it, exploded, and the gas, which is supplied through a 4in. main, was ignited. This was repaired, but on July 5, 1881, during another thunderstorm, precisely the same accident occurred."

From an interesting report, signed J. Gavey, on damage to a church at Cardiff (*L.R.C.*, p. 218), I make the following extract : "On examining more closely the surroundings of the lightning-conductor, I observed that the church gaspipe, an iron one, about 1¼in. in diameter, passed through the wall of the building about 6ft. from the conductor, and was carried in a direction corresponding with the hole caused by the explosion (see plan). I immediately concluded that this explosion was due to the current breaking across from the conductor to the gaspipe, and

Digitized by Google

on opening up the hole, I found this to be the fact. The conductor crossed the gaspipe at nearly a right angle, being about a foot above it. The under portion of the conductor bore evident marks of fusion, and, more interesting still, the gaspipe was slightly coated with a very thin deposit of copper, so thin that it perished in my attempt to remove it; but still there was an undoubted coating at one spot."

Continuing the account of this kind of damage, the following interesting remarks by Prof. Kirchhoff have a bearing on the important practical question whether gaspipes should or should not be utilised for earth; but their main utility lies in the proof afforded of the unique kind of danger which gaspipes introduce.

(To be continued.)

SECONDARY BATTERIES.*

BY J. APPLETON.

In considering the theory of the secondary battery, we will first trace the action which takes place in a fully-charged cell during the discharge. We have the two plates immersed in dilute sulphuric acid (H_2SO_4), the active material on the anode, or positive plate, being peroxide of lead, and on the cathode, or negative plate, spongy or finely-divided lead. During the discharge the positive plate gives up its oxygen, and the negative plate its hydrogen, so that when the discharge is carried as far as practical work will allow, we have at the anode peroxide, a lower oxide, and sulphate of lead.

This lower oxide is rapidly acted on by the sulphuric acid, and if the cell is allowed to stand in a discharged condition it becomes sulphate of lead. At the negative plate we have sulphate of lead. The chemical formula is

$$PbO_2 + 2H_2SO_4 + Pb = [PbO + H_2SO_4] + PbSO_4 + H_2O.$$

The compounds bracketed react, and the final result is

$$2PbSO_4 + 2H_2O.$$

There are two kinds of sulphate of lead—viz., $PbSO_4$, and Pb_2SO_5. The former is not very difficult to reduce or oxidise, but the latter, Pb_2SO_5, is the basic sulphate which is formed when the cells are in a bad condition, or are allowed to stand when discharged. It is very difficult, if not impossible, to reduce or oxidise this sulphate, and in charging cells in which this white basic sulphate is present, it will be noticed that it generally falls to the bottom of the cell in a fine powder.

The acid density of the electrolyte falls during the discharge as the sulphate is formed, and the specific gravity usually drops from 1·210 to about 1·160, though, of course, this depends entirely on the quantity of electrolyte in the cell. When the plates are charged the opposite action takes place: the electrolyte is decomposed, oxygen is taken up by the positive plate, and hydrogen by the negative plate. This goes on till all the active material is peroxidised and reduced in the respective plates.

When the greater part of the active material has been thus restored to its original condition, the oxygen and hydrogen not being absorbed by the plates so readily, pass off in bubbles, and it will be noticed that at this point the E.M.F. required to charge the cell rises very rapidly. This is due to the hydrogen bubbles on the negative plate, which causes a false or spurious back E.M.F. This, of course, lowers the efficiency of the cell, but can be overcome if the charging current is reduced when gas is given off from the plates. The active material will only absorb the oxygen and hydrogen at a given rate, and as the plates become charged the amount of active material to be acted upon is reduced, consequently the gas is given off in bubbles; but if the charging current is also reduced the quantity of gas formed by the decomposition of the electrolyte is less, and it is all absorbed by the plates. This is practically the theory of the lead secondary battery. There are differences of opinion as to the exact chemical action, but this will be sufficient for our purpose to-night.

As long ago as 1835 the highly negative or oxidising property of peroxide of lead was discovered by Munck, and in 1838 Shonbien described in the *Philosophical Magazine* the high E.M.F. of plates covered with peroxide of lead.

In 1843 Wheatstone experimented with platinum plates covered with peroxide of lead, and C. W. Siemens in 1852 made a battery using carbon plates impregnated and coated with peroxide of lead. In all these cases, however, the inventors used their plates as primary batteries only, and did not seem to know of the properties which they contained of being regenerated by charging. It was not till 1859 and 1860 that the principle of storage batteries was made known, when Gaston Planté published the result of his researches, and made the first reversible lead battery. His first cell was made of ordinary sheet lead. He took two sheets and rolled them up into cylinders, separating them by felt or strips of guttapercha, and then charged and discharged them in dilute sulphuric acid, reversing the direction of the current at each charge. He seems fully to have understood the importance of this discovery, and his experiments are fully described in a book he published at that time.

It is rather doubtful whether Planté used a coating of oxide mechanically applied to the lead plate, but Faure was the first to patent and introduce the pasted type of plate, and his are the fundamental patents for the batteries of this type. He pasted his lead plates with a paste of red lead mixed with sulphuric acid, using felt or parchment to keep the coating on. This plate was improved by Swan, Sellon, Volckmar, and others. Swan's patent for the perforated plates or grids is of the most important.

There have been many other batteries made, but I shall only mention to-night those which hold the most prominent positions. Messrs. Gladstone and Tribe, and also Fitzgerald, have been working in the direction of solid peroxide positives, and I shall say more about this type later on. An ideal secondary battery in my opinion is one which fulfils the following conditions. It must be cheap and durable, and able to take care of itself under ordinary working conditions; must charge and discharge rapidly, and give the greater part of its capacity with little or no fall of its E.M.F.; must be of very low internal resistance, and the internal resistance must be constant during the discharge, as if it increases at the same time the E.M.F. falls, the terminal E.M.F. of the cell is greatly reduced.

In a good cell the open circuit E.M.F. and terminal E.M.F. should fall in direct proportion. The cell must not require over-charging to keep it in good condition, but should be cut off from the charging source directly gas is given off when charging at a fair rate. Must be able to stand idle for a long time without local action taking place, and finally must make use of a fair percentage of the active material in the plates. When this state of perfection is attained it will be very easy to charge and discharge cells, automatically cutting them off by the rise and fall in E.M.F., and so working much more efficiently than at present. The modern tyes of secondary batteries are chiefly of two classes—one in which the active material is formed by the continued electrolytic action, and the other in which the active is mechanically applied to a supporting frame or conductor.

We will first consider the former class—viz., the Planté type of cell. The only batteries of this type at present in the market are, I believe, the Crompton-Howell and Elieson. The latter is not now being manufactured, but has done some fairly good work. (There is a plate here which shows the construction.) The Crompton-Howell battery has been designed, and is used chiefly, for central station work, where a very high rate of discharge is required for a short time. The plates are made from porous lead blocks sawn up into plates of the desired thickness, and formed by charging and discharging till the proper capacity has been obtained. They are very porous, so that the action penetrates right into the centre of the plates, and a large surface is exposed to the electrolyte. I have a positive and negative plate here; and you can see how porous they are, and yet mechanically strong.

I would just say a word here about the various electrolytes which can be used in secondary batteries. Undoubtedly sulphuric acid and water is the best for continual work, but for quickness of forming there are others which allow the oxidising action to penetrate more deeply into the surface of the lead. Sulphate of magnesia and sulphate of soda are very good, and with the former especially I have obtained excellent results. A very soft and porous peroxide is obtained with this electrolyte, but if the action is carried too far it disintegrates. A very good plan is to form for a time in sulphate of magnesia, and then change the electrolyte to sulphuric acid, which hardens the peroxide. The cathode does not fare so well with this electrolyte, as a thick film or scale forms (probably a silicate), which is a bad conductor, and increases the resistance of the cell. The Crompton-Howell battery gives very good results with rapid discharges. For example: T 25 type, containing 125lb. of lead, the external dimensions being 14in. × 12in. × 12in., can discharge at 100 amperes for four hours, and this can even be increased up to 500 amperes, provided the capacity is not drawn on for more than 100 ampere hours. This is very useful in certain cases, especially in central stations on the accumulator system, as practically the whole of the demand can be met for a short time from the batteries if anything happens to the engines or dynamos. The rate of charge for this cell may vary from 50 to 75 amperes. Beyond this there is a decided loss in efficiency; but the plates do not seem to hurt if there is plenty of electrolyte in the cells. In these cells each plate is separated from its neighbour by a perforated corrugated ebonite sheet, and in the latest type the plates are arranged in sections, so that any section may be removed for repairs or cleaning without interfering with the working. The second class of battery—viz., the one in which the active material is mechanically applied—is represented by the E.P.S., Drake and Gorham, Tatham, and Reckenzaun cells. The E.P.S. cells are too well known to need much description, but I will just mention some of the recent improvements that have been made. In the latest type the plates are put farther

* Paper read before the City and Guilds of London Old Students' Association at the Technical College, Finsbury, on Wednesday, May 8.

Digitized by Google

apart—viz., about ⅝in. This allows more room for the electrolyte, which is of very great importance.

It is very necessary that there should be sufficient electrolyte for the work which has to be done in the discharge. If there is not, only part of the active material in each little plug or pellet becomes useful, the centre part remaining, practically, idle and useless. This is not only wasteful but injurious to the plate, as the action occurs unequally in the plugs, and causes them to disintegrate. This occurs especially if a cell is discharged beyond its normal rate, as the edges of the plugs become softened, and there is nothing to keep them from falling out. By using more of the active material in each plug, not only is a greater capacity obtained, but also a higher rate of discharge.

In the 1888 type of cell the negative plates are joined by metallic conductors in three plates; this reduces and equalises the resistance of the plates, and causes the work to be distributed more evenly over the whole area. [31-L cell, traction cell, and unpasted grids shown.] The cells made for tramcar and launch work are capable of discharging at very high rates—viz., T 23 type, containing 23 plates and weighing 80lb. with box complete, discharges up to 50 amperes. This company have quite recently introduced a new form of grid which is very different from the old form, and is very interesting and ingenious. The two holes of the mould or chill in which the grids are cast have been moved corner-ways through a space just equal to half the size of a square, so that the corners of the squares in one half chill come exactly in the centre of the square on the other half of the chill. By this arrangement each plug or pellet of active material is part and parcel of the four surrounding ones, and, moreover, instead of the plug being in contact with the lead grid only round the four sides of the square, it is in contact with the back of the square in the other half of the chill.

It is by thoroughly investigating and studying these points that improvements are made, and I think a very much larger proportion of the active material in these batteries will eventually be really useful. Only about 15 or 20 per cent. of the theoretical energy contained in the peroxide is used in practical work, though this has been exceeded in laboratory experiments.

This tracing represents a cell of the same type, but of rather different construction. It is the latest pattern cell manufactured to the requirements of Messrs. Drake and Gorham, by Messrs. Elwell-Parker, of Wolverhampton. [Large cell and unpasted grids, with burred edges, shown.] The following figures, which are the results of some tests I took with some of these cells, may be of interest. The cells tested were two taken from a set of 31 L plate cells which had been in daily work for about 12 months, and were taken at random from the set, no trouble being taken to select them. The cells were fully charged to a gassing state, and were then discharged at the rate of 116 amperes for the two cells in parallel, or 58 amperes per cell. The internal resistance was ·00043 for the two cells. The discharge was continued without any stoppage for 16 hours, at the end of which time the E.M.F. had fallen 10 per cent., and the current to 109 amperes, or only 6 per cent. The internal resistance was ·00073. The capacity of the discharge was 1,860 ampere-hours, or 930 per cell. The cells were then recharged at an average rate of 90 amperes, and the efficiency in ampere-hours was 85 per cent. The capacity of these cells, as given by the makers, is 700 ampere-hours, so that there was an increase of about 30 per cent.

This, I think, speaks for itself, and shows that secondary batteries have reached a fair state of efficiency in practical work. A much higher efficiency would have been obtained if the cells had been discharged at a lower rate, but the test was made with the maximum rate of charge and discharge given by the manufacturers, and without a single stoppage in the discharge. The efficiency of a secondary battery increases as the rate of discharge is decreased, and when a cell is discharged at a very slow rate, nearly 100 per cent. efficiency in ampere-hours can be obtained, though, of course, this is useless for practical work.

Among the recent improvements in these cells, the following points may be noticed. The patent method of "burring" over the edges of the grid by which the plugs of active material are securely held in their places. This is done in a very ingenious way by means of a special tool, consisting of a number of discs fixed on a spindle. This spindle revolves very rapidly, and presses on the longitudinal bars of the grid, spreading the same out over the active material till the section of the grid is this shape. This rolling also tends to make the grids denser, thereby making them more durable.

Another important improvement is the patent method of supporting the anodes. When a plate buckles it always commences at the edges, so it was decided to hold the plates by the edge only and leave them entirely free in other ways. To do this, little lugs were cast on the edges, and these lugs fit into an ebonite frame, which is bolted to the negative plate and entirely supports the positive plates, the support being given where the buckling commences. By the arrangement of these lugs it is impossible for any oxide to lodge and form a short circuit between the plates. Only one separator is used with this method of holding the plates; this is a great advantage, as it allows the electrolyte to circulate freely. If the circulation of the electrolyte is bad in charging, the acid gets denser at the bottom of the cell. This is very bad, as a cell will very soon get into a bad condition if the density of the electrolyte varies in different parts of the cell. In the Tatham battery the objects aimed at are to utilise more of the active material to give a high rate of discharge, and to prevent the active material from disintegrating. This is done by mixing wood pulp with the oxide of lead to make it more porous, thus exposing more surface of active material to the electrolyte. I believe these cells have given very good results, although they are not in general use at the present time. [Plates shown.] There are other ways of doing this, one very good way being to mix the oxide into a paste with a solution of some salt, which evaporates when the plate is dry, or to mix a salt itself with the oxide, which will dissolve when the plate is put into the electrolyte. Care must be taken that too much porosity is not obtained, or the active material very soon disintegrates.

The Reckenzaun plate is constructed in a novel manner, the active material being moulded into little cylinders, and the lead frame is cast round them. (There is a sample plate on the table.) These plates are very strong, and can be bent into a cylinder without hurting them; the two here have been dropped on the floor, and are none the worse for it. There is a new cell being introduced in America, which is constructed on rather new lines, and which seems to be making a considerable stir there [cell shown]. The active material, instead of being pasted on is poured on to the lead-supporting frame in a molten state, and, it is said, is fused to it so well that the line of demarcation between frame and active material is hardly discernible. (Whether this is so or not time and work alone will show, as many secondary batteries work well for the first few months and then fail, no tests of secondary batteries are really conclusive unless carried on for 12 or 18 months at least.) The idea seems good, and if it can be carried out should produce a cell which will stand more than the ordinary amount of hard work and knocking about. The general arrangement of the cell is not so good as our English cells. For example: The negatives are connected to the metal box, while the positive plates are connected to the metal lid, a thin strip of wood keeping the lid from shutting closely on to the box. The cells are connected up in series by standing one box on the top of the other, so that the box of one cell is connected to the lid of the other. This, I believe, is considered to be a great improvement by the Americans; but I think when they have had as much experience in the maintenance of secondary batteries as we have, they will rather modify their opinion. There is another cell, about which a great stir was made in England about two years ago, which hardly belongs to either of the two classes. I refer to the Union, or lithanode cell. In this plate, as you see, the active material supports itself, and contact for charge and discharge is made through a platinum strip. [Plates shown.] This plate would undoubtedly be a great improvement on the other types of cells if its working capabilities were as good, and it is quite worthy of a little consideration, as it is certainly the nearest approach to a theoretically perfect cell that we have here to-night.

(To be continued.)

LONDON CHAMBER OF COMMERCE.

The following is the report of the Sub-Committee on Railway Rates:

To the Committee of the Electrical Trades Section of the London Chamber of Commerce.

GENTLEMEN,—We have carefully considered the provisions of the Railway and Canal Traffic Act, 1888, and have examined most of the proposed classifications of merchandise traffic, and schedules of maximum rates and charges submitted to the Board of Trade by the various railway companies in pursuance of the provisions of the above Act. We have also carefully compared these proposed classifications, in so far as they affect goods with which the electrical industry is concerned with the railway clearing house general classification of goods at present in force. The schedule to this report contains a comparative statement of the existing and proposed classifications of such goods.

The proposed revised classifications were submitted by the railway companies to the Board of Trade in February last, and the Board of Trade have extended the time for receiving notices of objections till 9th June next.

The category in which an article is placed determines the rate at which it is to be conveyed, and hitherto a revision of a rate was obtainable by a transfer of the article from one class to another. The classification to be made by the Board of Trade will, however, be permanent, and will be unalterable when once adopted by Parliament, except by a new Act.

With certain exceptions the revised schedules adopt the clearing house classifications. The signs have, however, been varied.

Digitized by Google

Class M (a) of clearing house corresponds to Class A of revised classification.

Class M (b) of clearing house corresponds to Class B of revised classification.

Class S of clearing house corresponds to Class C of revised classification (special class).

Class I of clearing house corresponds to Class I of revised classification.

Class 2 of clearing house corresponds to Class 2 of revised classification.

Class 3 of clearing house corresponds to Class 3 of revised classification.

Class 4 of clearing house corresponds to Class 4 of revised classification.

Class 5 of clearing house corresponds to Class 5 of revised classification.

Classes A and B are not of special interest to the electrical trades.

The classification in Class C applies only to quantities of two tons or upwards; if goods in Class C are sent in consignment of less than two tons, they are subject to the maximum and terminal charges in Class I.

The rates in Classes 1 to 5 apply to quantities exceeding 560lb., an increase of 60lb. on the minimum usually fixed in the existing Acts.

Insomuch as all the railway companies, whose proposed classifications we have examined, have adopted a common classification, we do not think it necessary in the annexed comparative statement of existing and proposed classification to do more than mention one company—the London and North-Western Railway Company.

Upon reference to the annexed schedule, it will be observed that the most serious variation in the proposed classification is the *entire omission* of the item "Dynamos and Electric Machinery," which, as the result of much effort, it will be remembered, was some time back transferred into Class 3, when not packed, and Class 2 when in cases. The effect of this omission might be that electric machinery might be classed either under "machines fitted up or partly fitted up not otherwise provided for," not packed, Class 4, packed Class 3, or under Class 5, the highest category, by being brought under the general definition of "all articles, matter, and things not hereinbefore classified."

Although this is the most important objection to the proposed classification, which in our opinion should be strongly raised in the interest of the whole industry, there are no doubt several other modifications which can be shown to be unjust and unreasonable.

The classifications call for the most careful consideration of the various branches of the industry, but care should be taken not to multiply needlessly the objections to be raised. For instance, although "storage batteries" have been removed from Class 2 to Class 3, they can still be conveyed at Class 2 rates by being declared as "electric accumulators."

Other objections, again, as that to the placing of empties in Class 5, will no doubt be made by the chamber on behalf of all trades.

There are a variety of other questions arising out of the provisions of the new Act, and of the proposed schedules of maximum rates and charges, and of the general conditions submitted by the railway companies, which merit the attention of manufacturers and traders in the country—*e.g.*, the general conditions which are proposed by the companies to govern the traffic, the question of terminal charges, the rates for small parcels, etc., but as these are not of special concern to the electrical industry, we recommend that the Electrical Trades Section should in these matters act in concert with the other sections of the chamber.

It would be well, however, for every member of the Electrical Trades Section to obtain the proposals of the railway company or railway companies of his district and examine and report on such questions as the selection of "large town" and "terminal stations," which have an important bearing upon the charges the companies will be entitled to make in respect of services before and after conveyance by rail.—Yours, etc.

Members of the section are requested to send in any additional facts, interesting to the trade, to the Secretary of the Chamber of Commerce, Botolph House, Eastcheap, E.C.

Schedule of Existing and Proposed Classifications in so far as they affect Goods appertaining to the Electrical Industry.

Description of Article.	Existing Classification.	Proposed Classification.
Acid, sulphuric	Under 2 tons in the carboys double 4.	—
Accumulators, electric...	2	2

COMPANIES' MEETINGS.

NEWCASTLE ELECTRIC LIGHTING COMPANY.

On Monday the first general meeting of the Newcastle and District Electric Lighting Company, Limited, was held in the County Hotel, Newcastle, to receive the report of the Directors as to the progress of the Company, and to transact the other ordinary business of the Company. On the motion of Sir Benjamin Browne, seconded by the Hon. C. Parsons, Mr. J. D. Milburn was voted to the chair.

The **Chairman** said that was a meeting which they were obliged to have under the Act, which enjoined that a general meeting of the Company should be held within four months of its registration, and it was customary on these occasions to give the shareholders a report of the progress of the work in such cases where no business of the Company had as yet been undertaken. As it was necessary to consult the local authority, and to get its permission to acquiesce in the establishment of the Company, they had very little trouble with them. They had then to make application to the Board of Trade, and to give notice for two months in order that anybody objecting to the establishment of the Company might give notice of opposition. The time for the notice would expire on the 26th inst., and, as far as the Directors knew, there was absolutely no opposition. They expected, therefore, by the end of the month, or the beginning of next, to have the sanction of the Board of Trade and its license to commence work. The Directors had been able to make several important contracts. The dynamos and engines had been partly contracted for, and he believed they could all be ready almost immediately. Then all the boilers required for the first section of the work of the Company had been contracted for, and would be delivered at the end of June or in July. The Company had, after careful consideration, chosen a site for the central station at Forth Banks, and as soon as the Board of Trade license had been received the seatings for the boilers would be commenced with, the erection of chimneys proceeded with, and the Company would begin to lay the cables in order to supply the current to customers. The system of lighting adopted by the Company, after mature and careful consideration, was that of the moderate tension of 1,000 volts alternating currents, and it was thought that this system, which was pretty well used, and which was pretty familiar to most electric lighting companies, would be such as to give the consumer an excellent, steady light. The Company not only pretended to light Newcastle, but it had powers to light the district, and might have to adopt a higher tension—something like 2,400 volts alternating current, or even more—and under these circumstances the Directors had held it wise and judicious to lay such cables and such transformers as would carry the higher voltage. Some of their electric lighting friends in London were adopting these higher tensions, and the Company would have the benefit of their experience in that direction. At present the Company was going upon what might be called safe lines, and was adopting what was considered to be a very safe voltage, and one well within control. The machines adopted were those of the turbine system, well known in this district. It had been applied to several works, and also to a great number of steamships, and had given very great satisfaction. These engines had been ordered from Messrs. Clarke, Chapman, and Parsons, and were being constructed with the very greatest care, and he had no doubt they would give every satisfaction to the Company. The boilers, which were three in number, and of the high pressure of 140lb. to the square inch, were being made by Messrs. R. and W. Hawthorn, Leslie, and Co. in their works adjoining the Company's station at Forth Banks, and it had been a very particular care of the Directors to have more boiler power even than was necessary for the first section. So much for the work which had been going on in the way of erections. With regard to the business operations of the Company, the business staff of the Company had not been idle. They had been canvassing, and at the present they had signed applications for lighting amounting to 35,000 c.p. incandescent light, or 3,500 lamps of 10 c.p., which was about half the trade required to keep the first section fully going. They were daily increasing their connection, and now that the tradesmen and others likely to make use of the light saw that the Company was in earnest, and setting about its work in a business-like way, they gave their proposals very careful consideration, and the Directors believed the result would be that in a very short time there would be more business than the first section of the work would be able to undertake. The Directors were determined upon two or three points. The first was they were resolved to give a good and steady light; the second was they were going to ask a fair and sufficient price for it. There had been several electric companies which had come to utter failure, and for that he believed there were three reasons. The first was the heavy initial expenses; the second was the injudicious selection of machinery, plant, etc., and the third was the working at a price totally inadequate to the work. There must be a great many unknown elements in such a new thing as the electric light. And some of those companies had an absurd and Quixotic idea of entering into a war to the death with gas. That Company did not entertain any such notion. What they proposed to do was to give a light of a higher order than gas, at a higher price. But it was a matter of calculation whether that price would really be higher or not. Gas was often used in a manner utterly wasteful, and that waste was avoided in the use of the electric light. The Company intended to provide a brilliant and better light than gas—an innocuous and exhilarating and artistic light, altogether out of the reach of gas. The electric light would be an advantage in concert-halls, ballrooms, picture galleries, and a source of safety in places where delicate fabrics were stored, and that by reason of its incandescence, and absence of heat, and more especially by reason of the utter absence of the innocuous element allowing the air to be entirely unvitiated. They hoped, with the system they had adopted, they would be able to give an unvaried and splendid light at all times. And in doing that they were much in sympathy with the consumers, who did not want to have the light for the sake of saying they had it, but who wanted a first-class light. One of the first towns to adopt the electric light on a large scale was Milan, in Italy, where, not only was it in general use in shops, hotels, and private houses, but it had become the sole illuminant of the streets. The light in Milan had been supplied publicly for upwards of six years, and had given the greatest satisfaction. Since Milan started operations, all the great European capitals and a large proportion of the provincial towns had now almost, as a matter of course, their central electric lighting stations. In Paris and Madrid laws had even been passed prohibiting the opening of any theatre not fitted throughout with the electric light. Eighteen towns in Spain had adopted the new illuminant, and as many, if not more, in Italy had followed the same course. In America the advance made in electric lighting had been very rapid, nearly all the great cities taking to the new illuminant in a wholesale way both for street and interior lighting. The Electric Company of Berlin were now running 36,000 lamps of 16 c.p. each, at a charge of 9½d. a unit of 1,000 watt-hours, the dividend being 7½ per cent. last year. In special districts 800 or 900 lamp-hours per annum were used, and in residences 400 to 500 lamp-hours per annum. In Milan the streets were lighted by 350 arc lamps. Each lamp would be equal in illuminating power to about 50 of the street lamps in this town. The lamps were hung over the centre of the streets on wires stretched from house to house. The illumination of the streets was perfect, and added greatly to the attractiveness of the town. In Rome about 13,000 10-c.p. lamps and 200 arc lamps were being run at present, some of the lights being three miles distant from the generating station. Plant for about 36,000 lamps was in course of erection. Electricity in the form of motive power, as applied to traction, had already established for itself a firm footing in America. Tramway companies were making a most extensive use of the electric current for driving their cars. Electric cranes, lifts, hoists and motors were now largely used in factories and warehouses where the electric light was installed. Small electric motors had been fitted to sewing-machines on a large scale in important manufacturing establishments in the States. Bleaching, welding of metals, and aluminium process, were other applications and examples of the wonderful adaptability of electricity to meet everyday wants. And now, looking at things at home, they found great electric generating stations springing up all over London, and the demand for the electric light is rapidly increasing. The price the company intended to charge was 5s. for 10,000 watt-hours, or 6d. per Board of Trade unit, with discount to consumers according to the quantity of light taken. They had now something like 29 or 30 applicants for the light, some of whom had already begun to have wires laid on to their premises. The Directors had every confidence in the successful working of the Company, and did not fear anything about capital. The difficulty hereafter would be to refuse capital. The nominal capital was £50,000 in 5,000 shares of £10, and it was only proposed to issue 2,000 at present.

An extraordinary meeting was subsequently held, at which **Mr. Findley** moved the adoption of the articles of association.

Sir Benjamin Browne seconded the motion.

Mr. Angus supported the motion, which was put to the meeting and carried.

A vote of thanks to the Chairman ended the meeting.

NEW COMPANIES REGISTERED.

Crompton-Howell Electrical Storage Company, Limited.—Registered by Mackrell, Maton, and Godlee, 21, Cannon-street, E.C., with a capital of £19,600 in six founders' shares of £100 and 19,000 ordinary shares of £1 each. Object: to carry on the manufacture and sale of secondary batteries, and to take over the business of the Crompton-Howell Electrical Storage Company. The first subscribers are:

J. Albright, and J. C. Howell. Qualification, £500 shares. Remuneration, £50 per annum each.

Keswick Electric Light Company, Limited.—Registered by Waterlow Bros. and Layton, Limited, 24 and 25, Birchin-lane, E.C., with a capital of £5,000, in £1 shares. Object: to carry on at Keswick the business of electric light manufacturers. Registered without articles of association, and, consequently, the regulations of table A in the first schedule to the Companies Act, 1862, apply.

Mexican Southern Railway, Limited.—Registered by Ashurst, Morris, Crisp, and Co., 6, Old Jery, E.C., with a capital of £1,000,000 in £10 shares. Object: to construct or acquire and equip, maintain and work railways, tramways, lines of telegraphs, telephones, or other means of communication or appliances of a similar nature in the Republic of Mexico; to acquire mining powers, rights or easements over any railway, tramway, or line of electric wire; to carry on the business of carriers of passengers and goods in all its branches by land and water, and that of transmitters of messages. The first subscribers are:

	Shares.
E. H. Clarke, Bartholomew House, E.C.	1
Lord Norreys, 3, Lowndes-street, S.W.	1
B. L. Rose, 1, Cromwell-road	1
T. H. Weguelin, 31, Sackville-street, W.	1
W. White, 10, Waughton-road, Anerley	1
W. Adams, 168, Friern-road, Dulwich	1
G. Lucas, 80, Bartholomew-road, N.W.	1

The number of Directors shall not be less than three nor more than nine; the first to be appointed by the subscribers to the memorandum of association. Qualification, £250 stock. Remuneration: Chairman, £1,000; other Directors, £400 per annum.

Medical Battery Company, Limited.—Registered by C. Doubble, 14, Serjeants'-inn, Temple, E.C., with a capital of £100,000 in £5 shares. Object: to acquire the business, goodwill, rights, privileges, contracts, copyrights, trade marks, patents, assets and property of whatever class now possessed by the Medical Battery Company, Limited, and to carry out an agreement made between C. B. Harness, the liquidator thereof, and H. C. R. Sharman, trustee for the new company. The first subscribers are:

	Shares.
Major C. G. Elers, Crewkerne	1
W. de Lorne, 34, Sidney-road, Stockwell	1
C. B. Harness, Potter's Bar	1
E. Crick, Montrose-road, Putney	1
A. Fleet, 39, Hatton-garden, E.C.	1
G. Wills, Crewkerne	1
R. Moffatt, Northumberland-park	1

The number of Directors shall not be less than three nor more than seven. The first are the present Directors of the Medical Battery Company, Limited; C. B. Harness is apppointed managing director. Remuneration, £1,000 per annum. The Directors, including the Managing Director, are to receive 5 per cent. on the net divided profits, to be divided as they determine.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended April 3 amounted to £2,844, and for the week ended April 10 to £3,086.

Submarine Cables Trust.—The report of the Submarine Cables Trust for the financial year to April 15 states that the revenue, including the balance brought forward, amounted to £20,567. The coupon due on April 15, 1888, was paid in two instalments—viz., £2. 10s. on October 15, and the balance of 10s. on November 15 last; £2. 12s. 6d. of the coupon due October 15, 1888, was paid on April 15 last. The balance of 7s. 6d. was paid on the 15th inst. The expenses amounted to £1,384, and the payments on account of the coupons to £19,018, leaving £165 to be carried forward.

Western and Brazilian Telegraph Company, Limited.—This Company, in their report for the half-year ended December 31, state that the total earnings amounted to £112,250, against £78,369, and the working expenses to £31,220, against £30,903. The Directors recommend a final dividend of 9s. per share, tax free, on the ordinary shares, making with the dividend paid in November, 5 per cent. for the year. The dividend for the year 1887 was at the rate of 4¼ per cent. per annum. In the case of shares which have been divided into preferred and deferred, 1s. 6d. per share of the dividend now recommended will be payable to the preferred shareholders, and 7s. 6d. per share to the deferred shareholders. The balance remaining is £29,561. The traffic receipts of the Company for the fortnight ended May 10, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £4,086.

PROVISIONAL PATENTS, 1889.

MAY 6.

7522. **An electric ignition for gas, petroleum, oil, or combustible vapour motor engines.** Herbert Sumner, 29, Dundonald-road, Kilmarnock.

7526. **An automatic compensating feed electric arc lamp.** Alfred Upton Alcock and Henri Galopin, 70, Market-street, Manchester. (Complete specification.)

7568. **Improvements relating to electric batteries.** George Horatio Jones, Southampton-buildings, Middlesex.

MAY 7.

7597. **Dry galvanic cells.** Carl Hermann Mehner, 15, Water-street, Liverpool. (Complete specification.)

7600. **Improvements in electric indicators.** Benjamin Charles Cross Cant, 73, Pembroke-road, Walthamstow, Essex.

7613. **A new boat, which shall be here called "The over-water boat, for steam, hot air, electric, or any other motive power or mode of propulsion."** Stephen Price, 33, Union-road, Newington-causeway, and Charles August Soderberg, 199, Southwark-bridge-road, London.

7619. **Improvements in and connected with electric batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

7645. **Improvements in underground conduits for electrical conductors.** George Washington Cook, 45, Southampton-buildings, London. (Complete specification.)

7647. **Improvements in electric motors and dynamo-electric machines.** Schuyler Skaats Wheeler, 46, Lincoln's-inn-fields, London. (Complete specification.)

MAY 8.

7673. **Improvements in electric wire insulators.** Arthur West Heaviside, 7, Grafton-road, Whitley, Newcastle-upon-Tyne. (Complete specification.)

7719. **Improvements in electric or galvanic elements or cells.** Paul Schoop, 46, Lincoln's-inn-fields, London.

MAY 9.

7773. **Improvements in means for actuating signals, switches, and gates on electric and other railways.** Robert Cooke Sayer, 11, Clyde-road, Redland, Bristol.

7774. **Improvements in means for supplying electric current to road vehicles, boats, and the like.** Robert Cooke Sayer, 11, Clyde-road, Redland, Bristol.

7780. **An electrical-firing apparatus for ordnance.** Richard Morris, 28, Southampton-buildings, Chancery-lane, London.

7796. **Improvements in supporting electric conductors.** Wm. Arthur Smith Benson, 24, Southampton-buildings, London.

MAY 10.

7808. **An electrical alarum and valve attachment to gauges (pressure, vacuum, speed or other gauges).** Arthur Julian, Church-street, Basingstoke.

7810. **Improvements in electrical instruments.** William Henry Douglas and Thomas Hugh Parker, 7, Cherry-street, Birmingham.

7856. **Improvements in electrical transformers.** William Claude Johnson and Samuel Edmund Phillips, 28, Southampton-buildings, Chancery-lane, London.

7860. **Improvements in holders for electric incandescent lamps.** Sydney Pitt, 24, Southampton-buildings, London. (Charles Lemon, New Zealand.)

MAY 11.

7868. **Improvements in electric meters.** Walter Emmott, Square-road, Halifax, and William Ackroyd, Royal Insurance Buildings, Halifax.

7870. **An improved electric generator.** Joseph Gozo, 41, George-street, Portman-square, London.

7883. **Improvements in electro motors and apparatus used therewith for dental and other purposes.** Thomas Cuttriss, 72, New Briggate.

7894. **Improvements in the method of distributing electricity by means of alternating currents.** Llewelyn B. Atkinson, Woodfield-road, Harrow-road.

7895. **Improvements in dynamos, motors, and motor-generators for use with alternating currents.** Llewelyn B. Atkinson, Woodfield-road, Harrow-road.

SPECIFICATIONS PUBLISHED

1888.

8809. **Electric switches.** Lake (Bergmann.) 8d.

8905. **Electric batteries.** Lahousse and Co. and Collé. 8d.

NOTES.

Westinghouse in London.—The Westinghouse Electric Company have taken offices in Gresham-buildings.

Lighting the Vestries.—St. Martin's Vestry Hall is now lighted by electricity, the result being an unqualified success.

Civil Engineers.—Sir William Thomson and Sir Henry Bessemer have been elected honorary members of the Institution of Civil Engineers.

The Institution.—The discussion of the paper by Mr. Mordey, "On Alternate Current Working," before the Institution of Electrical Engineers, will take place next Thursday, May 30th.

Telpher Lines.—The United Electrical Engineering Company are actively engaged upon a new telpher line at East Pool, near Truro, for the transportation of tin. The length of the line is about 1½ miles.

Electric Welding.—The Thomson Electric Welding Company are reported as being overcrowded with orders, and work is being pushed forward with great energy at their factory at Lynn, U.S. It is expected they will shortly have to increase their premises.

Overhead Wires.—It is curious to find that while New York is insisting upon all overhead wires being taken down, at Boston, U.S., authority has been granted for the introduction into the heart of the city of the overhead wire system for the Thomson-Houston electric cars.

Society of Arts.—A paper will be read before the Society of Arts next Tuesday at 8 p.m., on "The Westinghouse Alternating System of Central Station Electric Lighting in the United States of America," by James S. Humbird. The chair will be taken by W. H. Preece, F.R.S

Old Students' Conversazione.—The conversazione of the Old Students' Association with exhibition of instruments and apparatus at the Finsbury Technical College, which opened yesterday, will continue this (Friday) evening, for visitors wishing to inspect the college and exhibits.

Ship Lighting.—Amongst the ships recently fitted with the electric light by Messrs. Paterson and Cooper are the screw steamers "Islander," Curfew," "Ardle," "Dundee," "Cambria," "Pladda," "Dean," "Modjeska," and the steam yacht "Tighnamara." The firm has several ships in hand being fitted up.

Windsor.—At the Windsor Town Council an application was considered from the Windsor and Eton Electric Lighting Company for lighting powers within the borough, and was referred for consideration to a committee composed of members of the Authority who are not interested in the gas company or the proposed electric light company.

Electric Tramcars in Paris.—For some time an electric car has been running in Paris between the Place de la Madeleine and the Levallois gate. Faure-Sellon-Volckmar batteries are used with a Siemens motor. The power is communicated to the wheels by belting, and the motor is capable of exerting 12 h.p. The car is similar in appearance to the ordinary tramcars.

Hastings.—The Hastings Electric Light Company have declared a dividend of 3 per cent., free of income-tax. The company now supply about 1,000 lights, and the directors feel an enormous increase could be at once made if sufficient capital was available for laying down new mains, and they are not without hope that arrangements can be made by which public and private lighting from this station can be vastly extended.

St. Helen Tramways.—Mr. John Waugh, of Bradford, has purchased for the sum of £23,000 the whole of the plant and outfit of the St. Helen Tramways, which ten years ago cost £87,500. There are 10 miles of tramway, 75 horses, and 25 cars. Possibly Mr. Waugh appreciates the earning power of electricity, and is intending to substitute his 75 horses by accumulators. There is evidently a good chance at St. Helens to regain lost ground in tramway work.

Magneto Morse Sounder.—Mr. Campbell Swinton has recently constructed a magneto Morse sounder, on the principle of his well-known magneto bell. The play of the transmitting lever is made less, and the bell hammer is made to hit against two buffers, arranged to give different notes when struck. The absence of battery will make the magneto sounder exceedingly useful for field telegraphing, and the instrument has been sent to the War Department at Chatham to test.

Liverpool Music-Hall.—The extraordinary commercial success of the Empire and the Alhambra Music-halls in London, has led the proprietors of the Alexandra Theatre and Opera House, at Liverpool, to bring out a scheme for converting this place into a Liverpool Empire Theatre of Varieties. Structural alterations will be made to enable the premises to accommodate between 3,000 and 4,000 people, and the electric light plant and fittings will be correspondingly extended.

Leeds.—At the meeting of the Electric Lighting Committe of the Leeds Corporation last Friday, Mr. Howson, the borough engineer, reported that two estimates had been received for lighting the central district of the town. The borough engineer was directed to make further enquiries as to the outlay and likelihood of obtaining customers, and to report to a future meeting. The committee wish to act with the desire of thoroughly safeguarding the interests of the ratepayers.

Electric Street Railways in America.—Our esteemed New York namesake gives a list of the electric railways now in operation or in progress in America, from which we gather that there are now a total of 69 roads with a length of 346 miles, running 512 cars now in operation, while there are constructing or under contract 45 roads with a total length of 202 miles, with 360 motor cars. This is a splendid showing for the progress of electric traction in the States.

An Experimental Club.—A gentleman who has a comfortable electrical laboratory at Wood Green, with a considerable amount of apparatus, writes to us to say that he is desirous of forming a club for the purpose of conducting electrical experiments. He mentions that there are special facilities for conducting static experiments with reference to lightning-rods. Any of our readers who wish to obtain further particulars of the proposed club can leave a note to that effect at our office.

Edison's Iron Process.—A new Jersey company, in which Edison is supposed to be interested, has recently bought a tract of eight acres of iron ore lands. It is said to be the intention of the company to experiment with a

Digitized by Google

new electrical process of reducing ore. The proceedings of the company have been shrouded in mystery, and have so excited the curiosity of the residents, that someone broke into the premises and stole all the diagrams relating to the building, evidently hoping to obtain the key to one of Edison's most valuable discoveries.

An Electric Waggonette.—At the Kent County Council, an application was read last week from Mr. Link, of Kent House, Sydenham, asking for permission to run an electric waggonette on the roads in the district. Mr. Low said he ought to go to the London County Council, that being the proper authority for the district mentioned. A member suggested that Mr. Link might want to come into the district under the Kent County Council, and that he be allowed to take out a license for a locomotive, for that was what his "waggonette" really was.

Halifax and Bermuda Cable.—A correspondent writing to the *Financial News* remarks that the advice given in that paper to intending investors to read the agreement with the Government in order to ascertain the conditions under which the subsidy is granted, though, perhaps, not necessary for late investors in the Submarine Telegraph Company, whose property has recently been all but confiscated by the Government, nor to the directors of the new company and their friends, yet to widows and small investors the warning is prophetic. The kind of confiscation which has occurred is described in another note.

Train Lighting on the Midland.—The Midland Railway Company have been making experiments in the electric lighting of trains, and have adopted a system patented by Mr. Langdon, electrical engineer of the company. The dynamo is placed in the rear guard's van, which charges a series of accumulators placed in each carriage. The accumulator contains sufficient for 12 or 14 hours' light, so that the train may be taken to pieces and the light be still available. The light will be used first on the 5 p.m. train from London to Manchester, and other trains will probably also be fitted shortly.

Hull.—A meeting was held last week in Hull to consider the introduction of electric light into that town. The chairman of the meeting (Mr. R. Murray) said there seemed to be a strong feeling against the light due to the unsatisfactory experiments in 1886, when insufficient plant was employed. He put the cost of the necessary plant roughly at about £6,000, and estimated that the cost to consumers might be made less than that of gas. It was eventually decided that the promoters of the scheme should canvass the district it was intended to supply, in order to be in a position to approach the Corporation with a definite proposal.

Technical Education in India.—Lord Ripon's viceroyalty, and the jubilee of the Queen's reign, have together been celebrated in India by the institution of a Jubilee Technical Institute, which has just been opened in Bombay by Lord Reay. The subscriptions of these two funds were supplemented by grants from the Government and the Corporation of Bombay, and devoted to the founding of a technical institute, and Sir Dinshaw Petit presented a noble building. The formal opening, as mentioned, took place recently, although the institute has, in fact, been open for several months. It already numbers 240 students, and nearly half as many more are waiting nomination.

Another Electric Railway Proposed.—On the invitation of some of the leading gentlemen in Brechin, Mr. A. R. Bennett addressed a public meeting in that town on May 16th, on the subject of electric railways, and more especially in connection with a proposed line from Brechin to Edzell, a distance of six miles. There was a large attendance, and the meeting resulted in the appointment of a committee (consisting of Provost Mitchell; Mr. Shiel, factor to the Earl of Dalhousie; Mr. Lamb, manufacturer; Mr. Valentine; Mr. Anderson; and Mr. Philip, Bank of Scotland) to procure estimates and approach the proprietors whose land is required, with the view of avoiding, if possible, the necessity of an Act of Parliament.

The Telephone Amalgamation.—According to the *Financial News*, the arrangement by which the telephone companies will carry out their scheme of amalgamation without the necessity of obtaining the consent of the Post Office authorities is now complete. Instead of forming a new company—a plan which involved a transfer of licenses —the National Telephone Company will purchase the business of the United and the Cheshire Companies by the issue of its own shares to these companies in proportions which are equivalent to those originally proposed. All the licenses, as granted, extend to the whole of the United Kingdom, so that all the department has gained by taking advantage of a technicality has been the satisfaction of delaying the scheme for a few weeks. The amalgamation will take effect as from May 1, and, as merely formal meetings of shareholders are now required, may be said to be concluded.

New York Tenders.—In contemplation of the proposed public lighting of the City of London by arc lights, tenders for which will shortly come before the Commissioners of Sewers, it will doubtless be interesting to compare similar tenders recently received for the lighting of New York. These were as follows: The Brush Company, 441 at 35 cents each a night outside the subway district, and 65 cents where the subways are to be used; the East River Company, 421 lights at 35 cents, and 68 cents in the subway districts; the United States Company, 429 lights at 35 cents; the Harlem, 89 lights at from 35 to 60 cents; the North New York Company, 28 lights at 35 to 60 cents; and the Mount Morris Company, 878 lights at 28 to 55 cents. The latter company at present furnishes only 18 lights, at the rate of 32 cents, and its tender is in competition with the whole of the others with the exception of the North New York.

Recording Voltmeter.—A recording Cardew voltmeter is being made by Messrs. Drake and Gorham, in which the long fine wire inherent to this class of voltmeter is made to go over a series of small pulleys and then acts upon the end of a pointer. This makes the instrument much more compact than the ordinary form. A spring bar takes up the slack, and the readings can be adjusted as desirable. The variations of potential of a battery or circuit can be continuously recorded by passing a strip of lined paper slowly past the pointer. The moving power for feeding the paper will be obtained from an electric pendulum, the impulses from the electromagnet being given about once a minute by a small trailing piece, which catches in a little slot, and touches two contacts together when the swing gets below a certain amplitude. The instrument is likely to prove extremely useful for installations where a record of the electric pressure is required.

Folkestone.—At the last meeting of the Folkestone Town Council, the Electric Lighting Committee brought up a report, which recommended that as the gas company would not accede to the request of the committee to allow

Digitized by Google

certain lamps to remain unlighted with gas, the original agreement with Messrs. Crompton should remain the same, except as regarded the date, which should be altered from July 1, 1890, to August 10, 1889, and that they should apply for a license to supply private consumers with the electric light, in which application they should be supported by the Corporation. Also that notice be given to the gas company to discontinue the contract between them and the Corporation on July 1, 1890. After a great deal of discussion, especially as regards the private lighting, the motion was eventually put to the meeting and carried by eight to three. Mr. Thompson then moved that notice of termination of the contract with the gas company on July 1, 1890, be given, and this was also carried.

Liverpool.—The adoption of the electric light in Liverpool is rapidly extending in the business quarters, most of the banks, hotels, theatres, and many business houses being now lighted. Underground conductors have been laid in the principal streets, and the houses already lighted by overhead wires have been connected quietly to the underground mains, and many fresh houses are continually being connected. The overhead wires in most cases are taken down, and other streets, excluded from the first license, are being laid with mains under an extended license received from the Board of Trade, with the consent of the Corporation. The light will be available for the ensuing winter in all the leading business streets, and the three central stations of the Liverpool Electric Supply Company are being extended, and new machinery being put down. We understand that the number of lamps now connected with the company's mains is more than four times the number at this time last year.

Auxiliary Accumulator Cars.—In the case of a tramway proposing to run accumulator cars, but where there is one steep gradient on a long level run, it has been proposed to use an auxiliary electric engine to help the cars up the steep part, as is now the practice with horses. The disadvantages of having very large motors on each car, and of taking an excessive discharge from the batteries, would be obviated. Arrangements for altering the ratio of speed and power by gearing are likely to be far more useful in ordinary cases, but it is possible that circumstances might arise when the adoption of this suggestion would solve a difficulty, and prove more economical, both in maintenance and first cost, than by the adoption of more costly gearing for each car. The passenger cars could then be fitted with light batteries sufficient for ordinary running, and the auxiliary engine would be stationed at the steep part, and be kept working there during the whole day. The saving in outlay for batteries and for gearing might be far more than the cost of the auxiliary engine in a system requiring a large number of cars.

The "O.S.A." Journal.—We have received copies of the first number of the *Journal* of the City and Guilds Institute, Nos. 1, 2, and 3. In these appear some really valuable papers, originally read before the Old Students' Association, some of which we have been pleased enough to publish in this paper. The remaining space of the numbers is taken up with tales and amusing pieces on quasi-scientific subjects, with a number of third-rate jokes and quips which would be better omitted, and the space occupied with subjects more suited to the requirements of a journal catering for the interests of past and present students. The discussion and notes upon the Old Students' meetings, doings, wants, and aspirations, are a far more useful and interesting department, which it would be well to enlarge upon. The *Journal* has a most useful future before it for uniting the forces of the rising technical generation. We wish it all the success it deserves, and hope all old students will subscribe. The *Journal* of the Franklin Institute, now an acknowledged authority, took rise, it may be remembered, in a similar undertaking

Waterproof Moter.—Mr. Sprague some time ago promised a motor whose armature could be washed down with water without injury. Mr. S. D. Greene, of the Sprague Motor Company, New York, reports that they have now accomplished this fact. An armature, after being heated, was allowed to soak in a barrel of fresh water for 24 hours, and upon removal it was tested and found to be perfectly sound. It was then put into a barrel containing a strong saline solution, where it was allowed to remain for another 24 hours. At the expiration of this time it was taken out, and immediately put into a machine and run for two and a-half hours on a load averaging one-third greater than the proper load. The armature at the end of the run was as sound as when the experiment began. Under these circumstances, it must be evident that the armature is exceedingly well protected, and the "delicacy" of this part of the motor practically a thing of the past. The Sprague Company have made arrangements by which this method of waterproofing their motor-armatures can be carried out on a large scale, and in future all their street-car motors will be treated in this way.

Cable Subsidies.—The Chancellor of the Exchequer, in reply to Mr. Henniker Heaton, in the House of Commons on Friday, stated that he had found some difficulty in ascertaining exactly the amount expended on submarine telegrams from England by the various departments of the Government, as the messages do not necessarily pass through the Post Office. Roughly, the total cost of such telegrams in 1888-89 was something under £16,000. Last year's votes show that subsidies amounting to £49,000 net were paid by the Imperial Exchequer to submarine telegraph companies. With reference to the subsidy of the Australian Government to the cable companies, he understood that the Eastern Extension Telegraph Company has laid two cables to Australia. The one which was laid first is unsubsidised, but the Australian colonies pay an annual subsidy of £32,400 for the second. No contribution is made from Imperial finances. He could not say that he was prepared to consider the advisability of appointing a commission to consider and report on the whole question of telegraphic communication between England and the various parts of the empire.

Electric Train Lighting in the Argentine.—The recent terrible accident of the Buenos Ayres and Rosario Railway, where a kerosene lamp set fire to the cars and burnt some of the passengers to death, has caused the Argentine Government to enact that no oil lamps shall be used in passenger cars after May 23 of this year. Before news arrived of the accident, the Central Argentine Railway had already ordered that the electric light should be supplied to a couple of coaches, and had also arranged that the other coaches which were then in construction should be so built that the electric light could be added to them without having to alter the framework of the coach. The cost is about £45 to each Pullman coach. Since that accident occurred, the electric light has been ordered to be applied to half a-

Digitized by Google

dozen coaches which were going out to the Northern Railway. The experiment will also be tried of compressed gas as against electric light. The dynamos for generating electricity to light the station at Rosario having become insufficient in consequence of the very great extension of the works, and other dynamos of a much larger capacity have been ordered.

The Traffic of the Metropolis.—The state of the street and railway traffic in London is already causing wise men to consider further schemes for rapid transit to the immediate suburbs, and Mr. J. Stephens Jeans's paper on this subject before the Society of Arts was opportune. A number of interesting statistics were given as to the various services, and also as to the accidents that occur, the light butcher's cart being the worst offender in this respect. The electric railways already progressing or proposed were mentioned. Mr. Jeans suggested the organised establishment of further quick-running cars, buses, or even overhead railways, to certain terminal points in the suburbs, and suggested the society might offer prizes as to the best means of dealing with the evils of street traffic. In the discussion, Major Flood Page, alluding to the Southwark Subway, stated that he was in conversation with a member of the firm who were going to work the line by electricity, and learnt that they were well in advance of their work, and that they would deliver the machinery as soon as the subway itself was ready. Major Page pointed out that there was here to be a three-minute service, which would mean no less than 2,300 train-miles per day.

American Institute of Electrical Engineers.—At the annual meeting of the American Institute of Electrical Engineers, to be held at New York this month, some interesting papers on electrical subjects are promised. The following is given as the list of papers to be read by the authors: "Modern Views on the Nature of the Electric Current," with experiments, by Prof. H. A. Rowland, of Johns Hopkins University; "The Inherent Defects of Lead Storage Batteries," by Dr. Louis Duncan, of Johns Hopkins University; "Motor Regulation," by F. B. Crocker; "The Measurement of Telephonic Currents," by Prof. Chas. R. Cross, of the Massachusetts Institute of Technology; "The Relation Between the Initial and Average Efficiency of Incandescent Lamps," by W. H. Peirce; "Some Results with Storage Batteries in Train Lighting," by Alexander S. Brown, of the Pennsylvania Railroad; "Magnetism, and its Relation to Induced E.M.F. and Current," by Prof. Elihu Thomson; "The Efficiency of the Arc Lamp," by H. Nakano, with an introductory note by Prof. E. L. Nichols, of Cornell University; "The Personal Error in Photometry," by Prof. E. L. Nichols; and "The Spiral Coil Voltameter," by H. J. Ryan, of Cornell University.

Natural Electricity.—An extraordinary tale comes from Burmah. Mr. Ronald H. King, an electrician well known to the Burmese, while on a prospecting and shooting expedition in the island of Labuan, is said to have discovered a mineral from which electricity can be obtained without apparatus of any kind whatever. The mineral is described as being in the form of a black stone, of excessive hardness, and very great specific gravity, being nearly as heavy as platinum. A small block in the shape of an irregular cube, measuring 4·3in. one way by 5·2in. the other way, was brought away, and, on bringing it into the testing-room, a strong effect was noticed upon the galvanometer. At first it was thought that the mineral was an ordinary lodestone, but on tests being made, it was found that the force was more akin to that of an electromagnet, and that a strong current would flow when the mineral was connected in a circuit. Further tests revealed that a difference of potential of 47 volts could be detected at the extremities, the internal resistance of the mass being 20 ohms. The block appears to waste away very slightly, leaving a slight grey powder upon the surface when connected up for some time. The electrician now uses the block to light a couple of incandescent lamps in his laboratory! We should like to see it.

Cardew's Safety Device for Transformers.—One of the great dangers with alternating currents is that the primary current may by some accident get into the secondary circuits by defective insulation in the transformers. Captain Cardew has devised an ingenious instrument, which is being made by Messrs. Drake and Gorham, to obviate this defect, and cut out the whole circuits if such an accident were to happen. The first instrument of the kind, which we were shown the other day, is to be exhibited at the Old Students' conversazione at Finsbury. It consists essentially of a very thin piece of aluminium foil, in the shape of two discs joined by a strip, lying loosely between two metal plates insulated from each other. These plates are connected respectively to the secondary circuit and to earth. If such an accident as that mentioned took place, the thin disc is attracted by electrostatic action due to the high potential of the primary, and touches the top plate, immediately connecting it to earth through the bottom plate. The slight leak to earth of the primary causes a fine fuse to go, and this short-circuits for a moment the primary, which, of course, causes both fuses to go and cuts out the transformer and the whole installation at the main fuse. Mr. Ferranti has, we believe, tried them on the Grosvenor circuit, and has ordered two dozen for fitting to installations.

Land Cable Telegraphs in Germany.—In Germany the telegraph lines are to very large extent laid underground in a cable network, communicating by one way or another to all parts of the empire. The saving in repairs and loss from the spring and autumn storms has been so great that more than one cable line has already paid for itself. Apart from the loss by breakage, it was often days before communication could be obtained, and the receipts of the telegraph department were seriously affected. At present, even if a storm caused damage to the telegraph posts in different parts of Germany, telegraph messages can still be forwarded by the cable lines. There are still occasional interruptions, but no telegrams have now to be refused, and the saving is stated at many hundred thousand marks yearly, and the working is more regular than the overhead lines by reason of the freedom from accidental disturbances. The cable stations in Germany are at Strasburg, Metz, Cologne, Emden, Bremen, Hamburg, Kiel, Stettin, Dantzic, Königsberg, Thorn, Posen, and Ratibor. There are no cable lines in South Germany, owing to the mountainous nature of the country. The cables cross Germany in all directions, so that in difficult cases, in the most roundabout way, any place of importance in Germany may be reached. The importance of these land cable lines in time of war is exceptionally great. Communication in the late war was liable to interruption during storms; but now the army authorities are relieved from anxiety on that head.

Zinc Recovery.—Our old friend, "recovery of products," has turned up again, this time in the shape of The General Zinc Recovery and Lighting Company, Limited,

Digitized by Google

with offices in Deansgate, Manchester. We all know the phrases employed—new process, engine power prohibitive, no trouble and annoyance, primary battery, charged once a fortnight, etc. The new process consists in reconverting the exhausted solution by "a process only lately discovered," several thousand gallons to be treated at once, and the zinc recovered in a higher state of purity and used over and over again, or sold as chemically pure zinc. If it is a zinc-producing company, why not go to the zinc merchants and demonstrate the usefulness to them and try and get them to invest. But that is hardly the way to obtain money, and so electric light for nothing is the bait held out. We would not say it is impossible to recover the zinc, for of course it is possible; but the recovery requires power—probably engine-power with a dynamo, and if so, why not employ it for lighting, instead of all this paraphernalia of primary batteries, acid, accumulators, and carting backwards and forwards. Even without a mechanical process for recovery, the trouble with batteries for private consumers prohibits their use for the heavy currents required for lighting. To a technical mind the idea is absurd on the face of it, unless the promoters have something very different to say than we should expect they have. We presume they require money—from the public. They generally do. If so, we invite them to lay before us—as better able technically to judge in such matters than Manchester investors—any details which can possibly show there is any value whatsoever, as an investment, in a process for producing electric light and recovering the zinc.

The Weston Armature Patent.—American patents have a peculiar way of laying *perdu* for some years, and then coming out with a rush, and, like some savage beast, proceeding incontinently to devour all who may lay in their power. The Weston patent for sectional armatures s of this description, and although we hear little about it as affecting English dynamo manufacturers, it appears as if it were going to be a very formidable apparition to most American ones. It seems that both Edison and Edward Weston filed in 1882, the former a month the earlier, a patent claiming an armature made of iron plates separated by interposed insulating material, and mounted on an insulated shaft, Weston also claiming broadly the armature of iron plates with interposed insulating material, without reference to the shaft or to the type of armature. By some oversight, Edison's patent was allowed to issue prematurely in 1882, but an interference injunction was allowed, and priority of invention has finally been accorded to Weston. Meanwhile, the Weston patents have been secured by the Westinghouse Company through the recent arrangement with the United States Company, the original owners. The Weston patent has at last been issued, and is apparently broad enough to cover not only dynamo and motor armatures, but transformers as well. As it is the common custom of almost all manufacturers to construct their machines in this manner, it can be realised what an effect such a monopoly will involve. The Edison Company are "timely wise," and have already arranged for a royalty. To decide upon general issues, the Westinghouse Company have commenced a trial case in the courts, and have selected the Manhattan Electric Light Company, of New York, who use the Fort Wayne, or Slattery system, as defendants. The position of the general makers outside the pale of the wily Westinghouse, unless they can efficiently alter their methods of construction or can arrange to pay a royalty, is therefore inclined to become precarious. It will be interesting to learn what they have to say to prevent the threatened ravage into the domain of what has hitherto been regarded as public property.

Submarine Telegraphs.—In Committee of Supply, on a supplementary vote of £67,163 for the purchase of the Submarine Telegraph Company's lines, before the House of Commons on Wednesday, Mr. Raikes explained the terms arranged with the French Government for a through foreign traffic, and expressed his belief that the new system, long urged by the commercial community, would prove beneficial to this country alike from an international, postal, and financial point of view. It would largely increase facilities for commerce, and would, in all probability, give the country a profit of £15,000 or £20,000 a year. After some remarks from Sir G. Campbell, who unfavourably criticised the arrangement, Mr. Henniker Heaton contended that far too large a sum had been paid to the Submarine Company for their cables and other property, and he moved a reduction of the vote as a protest against what he regarded as an extravagant and unbusinesslike arrangement. Mr. Shaw-Lefevre also commented unfavourably on some of the items of the vote, and strongly urged that efforts should be made to reduce still further the cost of foreign telegrams; and Mr. Labouchere, contending that the Submarine Company had made an exceptionally good bargain, especially complained of the item for bonuses to be paid to employés of the company not taken over by the Post Office, which he insisted ought not to fall on the country. Sir J. Goldsmid, however, defended the arrangement as just, both to the country and to the company; and ultimately the reduction was negatived by 221 to 128, and the vote agreed to. The *Times* in commenting upon this arrangement says: "It seems to be the inveterate practice of the Post Office to spring matters of this kind upon the House of Commons and the country with as little notice as possible, and with as little explanation as is compatible with the not too lofty standard of Parliamentary candour. Mr. Henniker Heaton complained, not without reason, that notice of the vote had only been given yesterday morning, and the Postmaster-General's explanations, adroit, ingenious, and courageous as they were, certainly did not meet the objections of his critics, though they sufficed to secure a majority for the vote. The convention whereby the tariff for telegraphic messages between England and France is fixed for the next ten years at 20 centimes a word, has now been concluded, and the House of Commons has sanctioned it, probably feeling that in the circumstances it had no choice. It secures a certain advantage in comparison with the former tariff, but we cannot pretend to think that it has been framed with sufficient regard to the public convenience, or with adequate economy of the public funds. It is a bad bargain and an extravagant bargain. Not only have we paid a price fixed, as the Postmaster-General acknowledged, 'by competent and experienced valuers' to the Submarine Telegraph Company for their property, but we have added 10 per cent. to that price as a *solatium* for the extinction of a monopoly which, as the Postmaster-General also acknowledged, they were not compelled to sell to the Government, and could not have sold to anyone else. In addition to this, we have paid £5,500 nominally to clerks of the company deprived of their employment, but really to the shareholders of the company, who could not, any more than the Government, have allowed their clerks to be turned adrift without some provision for them."

ELECTROLYSIS OF NICKEL SALTS.

BY ALEXANDER WATT.

The behaviour of solutions of metallic salts, under the influence of the electric current, appears to vary somewhat with different manipulators, examples of which I have before had occasion to direct attention to in former papers. In carrying out a series of experiments in the electrolysis of nickel salts, I have frequently found that the results were widely different from those obtained by other observers, and the only way in which I can account for such divergences—which in some instances were of a remarkably opposite character—is that the density ot the current employed and the metallic strength of the electrolyte must have been greatly different in each case. As an illustration of the differences referred to, I may mention that the late Alfred Smee, in his "Elements of Electro-Metallurgy," states that a solution of acetate of nickel yields a "black, powdery deposit, and is a bad one for obtaining reguline metal." Now, in my own experiments, I find that this salt, under the conditions stated further on, yields a good reguline deposit of a fairly good colour, and much softer than is usual with electrolytic nickel. In endeavouring to account for this wide difference between the results obtained by the gifted author of the work referred to and those which I have lately obtained, I venture to suggest that in Smee's experiments a far more powerful current must have been employed than was necessary for the reduction of metallic nickel from its acetate solution. Again, Merrick, employing the current from two Grove cells for the electrolysis of an acetate of nickel solution, obtained a good deal of the deposit in the form of black oxide, with a layer of reguline metal beneath. Now, with the current from two small Daniells —a battery of far lower E.M.F. than the Grove—I readily obtained a good reguline deposit of nickel from a solution of the same salt, and no trace whatever of black oxide. In pursuing electrolytic experiments with metallic solutions, I invariably make it a rule to commence with a low current and to increase the density as occasion may require, bearing in mind Douglass Jerrold's axiom, "hit a crown, but aim low." The density of the solution is the next consideration, and this is always modified, by dilution with water, until the most favourable condition is obtained for depositing reguline metal—the only useful aim in experiments of this nature. By adopting this method of procedure I have frequently obtained satisfactory results, even with solutions bearing a very bad character so far as their electrolytic behaviour is concerned.

The experiments which I am about to describe were conducted with the current from one or more small Daniell cells, according to the conductivity of the electrolyte, the anode being a plate of rolled nickel, furnished by Messrs. H. Wiggin and Co., of Birmingham, to whose courtesy, also, I am indebted for some excellent commercial salts of nickel, with which many of my experiments were conducted. The cathodes employed consisted of a series of brass plates 1in. wide by 3in. long, to each of which was soldered a copper wire. The current density ranged from ·715 to 1·131 amperes, the latter being the current from three cells arranged in series. In each case the current from a single cell was first tried, with nearly equal electrode surface, and a second, or third, cell connected whenever the current was found to be insufficient for obtaining a prompt coating of nickel on the receiving plate. It should be mentioned that in nickel-plating generally it is always advisable to employ a current strong enough to ensure a coating of the cathode almost immediately after immersion, or, as the Americans term it, to *strike* the deposit at once. When nickel deposition takes place slowly, and the object does not become coated with the metal almost instantly after immersion, it is a sure sign, all other things being equal, that the current is too weak. In ordinary nickel-plating, it is customary to employ a much larger surface of anode than that of the cathode or articles to be coated, which, even when the current is obtained from a dynamo-electric machine, appears to be absolutely necessary with solutions of the double sulphates of nickel and ammonia. When voltaic batteries have been employed, a still larger anode surface has generally been found necessary; but in the experiments which I have lately followed up I have endeavoured, whenever practicable, so to accommodate the current to the solution, or *vice versâ*, that a nearly equal surface of the electrodes would enable me to obtain a prompt "striking" of the film within a few seconds after immersion of the cathode. These I consider to be the proper conditions of working, and if they can be carried out in practice will involve less cost for nickel anodes—an object of importance when heavy cast anodes are employed, as I have often known to be the case.

1. *Acetate of Nickel.*—A solution was prepared by digesting recently-precipitated and moist carbonate of nickel in commercial acetic acid containing 15 per cent. real acid until a neutral solution of a rich green colour was obtained, which contained about four troy ounces of the dried salt per quart of solution, or, say, 16 ounces to the gallon. The current from a single cell was first tried, but the cathode, a clean brass plate, received no deposit of metal; a second cell was then connected in series, when a film of nickel soon formed upon the plate, which, although of a rather dark colour, was perfectly uniform and of a good reguline character. After about an hour's immersion, the plate was removed, rinsed and dried, and a steel burnisher applied, which readily brightened the surface, showing that the deposited metal was softer than the metal obtained from the ordinary double sulphate solutions. In this experiment, the anode surface immersed in solution was about *one-third less* than that of the cathode, and the deposit took place on both sides of the latter, which is not always the case with nickel solutions. The current which effected the deposit from this solution was about 1·012 ampere, the total surface of the cathode being six square inches.

2. *Acetate of Nickel by Electrolysis.*—It was next determined to ascertain whether the nickel anode would freely dissolve by electrolytic action in a solution of acetic acid, for which purpose one volume of commercial acetic acid was added to two volumes of water, and this was electrolysed with the current from three small Daniells in series. Under these conditions, a brass plate, used as the negative electrode, received a coating of nickel in rather less than an hour, the solution having acquired a slightly green tinge. It was next resolved to see if a stronger solution of the acid would be more prompt in its action, and for this purpose the undiluted commercial acid was tried, with three cells as before, when in about a quarter of an hour a brass plate became coated with a bright but wavy deposit of nickel of a good white colour.

3. *Acetates of Nickel and Ammonia.*—A solution was next prepared by adding to a strong solution of nickel acetate one of acetate of ammonia, and the bath thus prepared was electrolysed, as before, with the current from two cells, when a deposit of a good white colour was obtained upon a brass plate. During the electrolysis of this solution there was a good deal of gas given off at the anode, but very little at the negative electrode, where, however, minute bubbles of hydrogen were noticed to form slowly and to rest on the plate with great tenacity. In about 15 minutes a dense white foam surrounded the anode, caused by the evolution of minute bubbles of gas at that electrode.

4. *Acetates of Nickel and Chloride of Sodium.*—To a strong solution of acetate of nickel was added one of chloride of sodium, and the mixture was electrolysed with the current from two cells, which, however, proved to be too weak, so a third cell was connected, when a film of nickel soon formed upon a clean brass plate, which was of a very good white colour. When the third cell was introduced the deposition took place somewhat too speedily, therefore a portion of the anode was withdrawn from the solution, leaving the immersed surface of this electrode somewhat less than that of the negative plate.

5. *Acetates of Nickel and Potassium.*—A bath was prepared by adding to a strong neutral solution of acetate of nickel a solution of acetate of potassa. With this bath, which appeared to be a somewhat better conductor than the preceding, the current from two cells only was found sufficient to obtain a deposit of nickel on a brass plate, which occurred soon after it was immersed in the liquid. In this case there was only a moderate evolution of gas at the positive electrode, while there was none at all at the negative.

Digitized by Google

The deposited metal from this electrolyte was very uniform and white, and the surfaces of the electrodes were about equal. A bath of this composition might be useful for coating metals with nickel.

6. *Citrate of Nickel.*—A solution was prepared by digesting recently-precipitated and moist carbonate of nickel in a strong and hot solution of citric acid, in which it became freely dissolved, forming a green solution. The bath thus formed was first tried with the current from one cell, but as no deposit of metal took place a second cell was connected, when a film of nickel somewhat slowly formed upon a brass plate—the electrodes being of about equal surface. The colour not being white enough, a larger surface of anode was immersed, when the colour improved. It was noticed, however, that the metal deposited but slightly on the back of the plate. A better result was afterwards obtained by taking the current from three cells in series and reducing the anode surface.

7. *Nickel Carbonate in Sulphate of Ammonia.*—A solution was formed by adding moist carbonate of nickel to a strong and hot solution of sulphate of ammonia, in which the carbonate freely dissolved, forming a bluish-coloured solution. With the current from one cell no deposit was obtained from this bath, but when a second cell was connected deposition took place promptly ; the film, however, was not of a very good colour. There was very slight evolution of hydrogen at the cathode, and the deposit took place on both sides of the plate.

8. *Nickel Carbonate in Bitartrate of Potassa.*—A hot solution of the bitartrate (cream of tartar) was first prepared, to which was added, a little at a time, moist carbonate of nickel, each portion being allowed to dissolve before the next was added, until the solution became nearly saturated. From one to three cells were tried consecutively, but little or no metal was deposited upon the cathode, which, however, became coated with a copious gelatinous layer of a brown colour, doubtless hydrated oxide of nickel. This deposit occurred on both sides of the plate.

9. *Nickel Carbonate in Chloride of Ammonium.*—A hot solution of salammoniac, was first prepared, to which was added, gradually, as before, moist carbonate of nickel and the resulting solution, which was of a green colour, was then allowed to cool. With the current from the cell, a tolerably prompt deposit of nickel was received upon a brass plate, the colour of which, however, was of a yellowish tint. A second cell was then introduced, when the colour of the film greatly improved, and soon became of a good white colour. No hydrogen was liberated at the negative electrode, and the deposit occurred on both sides of the plate.

10. *Nickel Carbonate in Sulphate of Alumina.*—A solution was prepared by digesting moist carbonate of nickel in a hot solution of sulphate of alumina, in which the nickel salt became freely dissolved, forming a green solution. The current from one and two cells respectively was first tried ; but since no metal became deposited, a third cell was put in series, when it was found that a black granular deposit formed on the cathode, while a deep black coating also appeared on the back of the plate. After a few minutes a copious green crystalline deposit formed on the cathode, and fell off its surface to the bottom of the vessel—probably a basic salt of nickel.

11. *Nickel Tartrate.*—A solution of this salt was prepared by digesting moist carbonate of nickel in a strong and hot solution of tartaric acid until a nearly neutral solution, which was of a pale green colour, was obtained. With this solution, which was a poor conductor, no deposit of nickel could be obtained until three cells had been arranged in series, when a film of nickel of an indifferent colour slowly formed on a brass plate. It was noticed that the cathode became more fully coated with metal on the back than on the front—a peculiarity which I have observed, and recorded in some former papers in this journal on the "Peculiarities of Electro-Deposition."

12. *Lactate of Nickel.*—A solution of this salt was prepared by digesting moist carbonate of nickel in lactic acid, in which the nickel salt became readily dissolved, forming a green solution, which was afterwards diluted with water. The diluted solution failed to yield a deposit with the current from a single cell, and only a slight film was obtained with two cells ; with three cells, however, a brass plate became coated with nickel of fairly good colour soon after immersion. Beyond the fact that this weak acid readily dissolved the nickel carbonate, there was nothing of interest in the electrolysis of the resulting liquid.

13. *Phosphate of Nickel in Bisulphate of Potassa.*—A quantity of phosphate of nickel was first prepared by adding a solution of common phosphate of soda to a solution of nickel sulphate, and the resulting pale green precipitate was afterwards well washed with water. A strong solution of bisulphate of potassa (*sal enixum*) was next made, to which a portion of the moist precipitate of nickel phosphate was gradually added until the liquid became saturated, when a nearly colourless solution resulted. This was electrolysed with the current from three cells, but only a slight film of nickel was obtained—chiefly on the back of the plate. There was a vigorous evolution of gas at both electrodes.

14. *Nickel Phosphate in Cyanide of Potassium.*—A solution was prepared by digesting recently precipitated phosphate of nickel in a moderately strong solution of cyanide of potassium, the resulting liquid having a slightly brown tinge. With the current from three cells, no metallic deposit was obtained, but a red salt formed at the cathode, which diffused itself through the liquid ; a deposit of a black colour appearing on the surfaces of the anode. There was a copious evolution of gas at both electrodes.

(To be continued.)

CORRESPONDENCE.

FIREDAMP DETECTORS.

To the Editor of The Electrical Engineer.

Sir,—I should like to point out that Mr. Niblett is in error in supposing that the wire gauze used in the Davy lamp renders it safe in an explosive mixture of gas under all circumstances. In fact, under the modern conditions of ventilation, where very powerful ventilating currents are used, it is doubtful if any of the oil lamps now in general use are absolutely safe, or even practically safe under certain conditions, such, for instance, as the sudden emission of a blower of gas. In fact, one of the principal reasons why mining engineers are so ready to take up electric safety lamps is because there is absolutely no contact between the surrounding atmosphere and the glowing filament. And the only doubt which has so far been thrown on its safety has been the apparent uncertainty whether heat will remain long enough in the filament, in case of breakage, to ignite gas, if any be present.

Immediately you bring the gas into contact with a glowing metal, of whatever form, no matter that gauze may be present, you destroy this absolute safety.

Another point that I should like to mention is the detector that is required to take the place of the Davy lamp should equal it in simplicity, and should be capable of being placed in the hands of every practical working collier, and it should denote quickly and unmistakeably the presence of gas—not necessarily its percentage. The collier requires a guide to tell him when he is in a gaseous atmosphere for two reasons :

First, for the safety of the mine.

Secondly, for the sake of his own health, so that he may not be breathing a dangerous atmosphere without knowing it.

For the officials of the colliery an instrument showing in a simple and reliable manner the percentage of gas present will be of great service, but to the working collier such an apparatus would be useless.—Yours, etc.,

Sydney F. Walker.

P.S.—I trust the above remarks will be taken in the spirit in which they are given—viz., to help Messrs. Pitkin and Niblett in the work they have in hand.

MEDICAL BATTERY COMPANY, LIMITED.

To the Editor of the Electrical Engineer.

Sir,—My attention has been drawn to last week's *Electrical Engineer* containing particulars regarding the regis-

Digitized by Google

tration of "The Medical Battery Company, Limited." To prevent any misunderstanding, therefore, I shall feel obliged if you will kindly inform your readers that, in order to make further important advancements in the practice of medical electricity, and to obtain power to carry out Mr. Harness's idea of establishing a Free Electropathic Hospital, it was found necessary to alter our memorandum and articles of association. To meet the requirements of the Joint Stock Companies Acts, the directors have had to conform to the legal formality of re-registering the company. Mr. C. B. Harness has been appointed president of the company, and the title, capital, directors, and shareholders remain exactly the same as before.

It is intended to still further extend the spacious premises of the company, so as to meet every possible requirement for the perfect treatment of disease by electricity.—Yours, etc., CHAS. R. SHARMAN, Secretary.

London, W., May 20, 1889.

ON LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS.*

BY DR. OLIVER LODGE, F.R.S., MEMBER.

(*Concluded from page 399.*)

Injury to Gas and Water Pipes by Lightning.†

The city gas company of Berlin, having expressed the fear that gaspipes may be injured by lightning passing down a rod that is connected with the pipes, Prof. Kirchhoff has published the following reply: "As the erection of lightning-rods is older than the system of gas and water pipes as they now exist in nearly all large cities, we find scarcely anything in early literature in regard to connecting the earth ends of lightning-rods with these metallic pipes, and in modern times most manufacturers of lightning-rods, when putting them up, pay no attention to pipes in or near the building that is to be protected." Kirchhoff is of the opinion, supported by the views of a series of professional authorities, that the frequent recent cases of injury from lightning to buildings that had been protected for years by their rods, are due to a neglect of these large masses of metal. The Nicolai Church in Griefswald has been frequently struck by lightning, but was protected from injury by its rods. In 1876, however, lightning struck the tower and set it on fire. A few weeks before, the church had had gaspipes put in it. No one seems to have thought that the new masses of metal which had been brought into the church could have any effect on the course of the lightning, otherwise the lightning-rods would have been connected with the gaspipes, or the earth connection been prolonged to proximity with the pipe. A similar circumstance occurred in the Nicolai Church in Stralsund. The lightning destroyed the rod in many places, although it received several strokes in 1856, and conducted them safely to the earth. Here, too, the cause of injury was in the neglect of the gaspipes, which were first laid in the neighbourhood of the church in 1856, shortly before the lightning struck it. The injury done to the schoolhouse in Elmshorn, in 1876, and to the St. Lawrence Church, at Itzehoe, in 1877, both buildings being provided with rods, could have been avoided if the rods had been connected with the adjacent gaspipes.

"If it were possible," says Kirchhoff, "to make the earth connection so large that the resistance which the electric current meets with when it leaves the metallic conducting surface of the rod to enter the moist earth, or earth water, would be zero, and it would be unnecessary to connect the rods with the gas and water pipes. We are not able, even at immense expense, to make the earth connections so large as to compete with the conducting power of metallic gas and water pipes, the total length of which is frequently many miles, and the surface in contact with the moist earth is thousands of square miles. Hence the electric current prefers for its discharge the extensive net of the system of pipes to that of the earth connection of the rods, and this alone is the cause of the lightning leaving its own conductor."

[This, like many another theoretical remark, is not to be supposed true.—O. J. L.]

Regarding the fear that gas and water pipes could be injured, he further says: "I know of no case where lightning has destroyed a gas or water pipe which was connected with the lightning-rod; but I do know cases already in which the pipes were destroyed by lightning because they were not connected with it. In May, 1809, lightning struck the rod on Count von Seefeld's castle, and sprang from it to a small water-pipe, which was about 80 metres from the end of the rod, and burst it. Another case happened in Basel, July 9, 1849. In a violent shower one stroke of lightning followed the rod on a house down into the earth, then jumped from it to a city water-pipe, a metre distant, made of cast iron. It destroyed several lengths of pipe, which were packed at the joints with pitch and hemp. A third case, which was related to me by Prof. Helmholtz, occurred last year in Gratz. Then, too, the lightning left the rod and sprang over to the city gaspipes, even a gas explosion is said to have resulted. In all three cases the rods were not connected with the pipes. If they had been connected, the mechanical effect of lightning on the metallic pipes would have been null in the first and third cases, and in the second the damage would have been slight. If the water-pipes in Basel had been joined with lead instead of pitch, no mechanical effect could have been produced. The mechanical effect of an electrical discharge is greatest where the electric fluid springs from one body to another. The wider this jump the more powerful is the mechanical effect. The electrical discharge of a thunder-cloud upon the point of a lightning-rod may melt or bend it, while the rod itself remains uninjured. If the conductor, however, is insufficient to receive and carry off the charge of electricity, it will leap from the conductor to another body. Where the lightning leaves the conductor, its mechanical effect is again exerted, so that the rod is torn, melted, or bent. So, too, is that spot of the body on which it leaps. In the examples above given, it was a lead pipe in the first place, a gaspipe in the last place, to which the lightning leaped when it left the rod, and which were destroyed. Such injuries to water and gas pipes near lightning-rods must certainly be quite frequent. It would be desirable to bring them to light, so as to obtain proof that it is more advantageous, both for the rods and the building which it protects, as well as for the gas and water pipes, to have both intimately connected. Finally, I would mention two cases of lightning striking rods closely united with the gas and water pipes. The first happened in Düsseldorf, July 23, 1878, on the new Art Academy; the other August 19, last year, at Steglitz. In both cases the lightning-rod, the buildings, and the pipes were uninjured."—*Deutchen Bauzeitung.*

48. That lightning sometimes does things which is, on the hitherto available views, inexplicable, is evidenced by the following record by one who, of all others, made lightning-conductors his hobby, who acquired an immense amount of experience concerning them, and to whom the carrying out of probably the most perfect system of protection in actual use is largely due—I mean the late M. Melsens:

Note on the Lightning Flash at Antwerp Railway Station, July 10th, 1865. By M. Melsens.

"I have described this lightning stroke, which was very harmless, since all the damage was confined to the breaking of a square of glass in the roof of the covered station of the railway at Antwerp; but, in connection with it, I found myself confronted by so extraordinary a phenomenon that I had to search through all the descriptions of lightning strokes which might offer a certain analogy to this with which I have to do. It was only on looking through my notes again, and returning several times to the place, that I have ventured to describe this very extraordinary stroke, and I have only published it after a long time, when it seemed to me that I could establish it upon careful observations and experiments which seemed of a nature to corroborate my conclusions."

Mention made of nineteen lightning flashes, which present some analogy to that which struck Antwerp Station: "A few words are sufficient to show the peculiarity of the phenomenon. The lightning crossed a square of glass and produced in it a hole similar to that which would be produced by a projectile thrown upwards from below at a slow rate, say, from 30 to 50 metres per second, and travelling from earth towards the sky. The edges of the hole were melted. I have given a description of the experiments I made, together with Ruhmkorff, to prove that in reality lightning does travel from the earth towards the sky. The proof which I give of it seems to me decisive.

"The extraordinary fact, as I have remarked, is to see the lightning pass, by means of a very bad conductor, through a square of glass 4 millimetres in thickness, forming a parallelogram of 0m. 35 × 0m. 38, having angles of 83deg. and 97deg.

"The opening produced was at a distance of some centimetres from iron and lead conductors, which were in perfect metallic communication with all the iron of the station. The weight of this latter exceeds 120 tons. But the anomaly does not stop there. To the right and left of the glass roof in which the broken pane was, the covered platform of the station has a roof of zinc No. 13, presenting to the lightning a surface of 3,000 square yards. The weight of this zinc is not less than 15 tons. The three tall rods of the lightning-conductor are in immediate metallic contact with this zinc and with the conductor, and the whole is connected to 28 hollow columns, serving to carry off rainwater. The collection of these metals would allow one to suppose that they were well adapted to carry off lightning or any such disturbance easily; but in this instance it despised them, and chose a path entirely unexpected. Let me add that there was a shed some 62 metres from the station

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

built on hollow columns and iron framework, and the greater part of it roofed with zinc; moreover, about 40 metres on the opposite side were more sheds roofed with zinc ; the metallic surface was not less than 2,000 square metres. Moreover, in my investigation, I might mention plenty of other metals in communication more or less perfect with the earth, grids, sconces, gaspipes, telegraph wires, rails, etc. Besides, the whole of the platform may be considered as one large lightning conductor in perfect communication with a very damp earth, and offering hardly any resistance to the passage of the current from the building."

49. Of all the buildings in the world not wholly made of metal, the Hôtel de Ville at Brussels was and is the most perfectly and elaborately protected. No electrician exists but would a year ago have asserted, had they gone over it, that it was absurdly and exaggeratedly safe from damage by lightning. Last July it was struck and set on fire.

The case has been investigated and published in the *Bulletin de la Société Belge d'Electriciens*, for September and October, 1888.

It seems to have been owing to secondary or induced electric surgings in a horizontal bar of metal totally disconnected from anything ; not pretending to lead toward earth, and being some little distance below a stretch of lightning-conductor not offering itself as an object to be struck. On all the old views it was utterly insignificant. However, as a matter of fact, although not struck, although it did not probably even receive a side flash, yet the induced surgings set up in it, induced by Maxwell and Heaviside's electromagnetic waves, were so violent as to ignite some gas and cause a small fire. Had it been connected to the conductor, the sparking from it would probably have been stronger.

This occurrence, and certain sparkings in the wall paper of the Royal Institution (*Nature*, March, 1889), the sparkings, too, in the gilding of the present hall, are plain and straightforward intimations that the old views on the subject of electric conduction are hopelessly, and absurdly, and dangerously inadequate. It is time that the prophets of that old superstition were slaughtered by the brook Kedron.

Practical Questions.

50. There remains to consider what is to be the practical outcome of all this. What improvements in the erection and testing of lightning-conductors are possible. This is a matter well worthy of discussion, and eminently suited to it. It is a matter on which I have not the slightest wish to be dogmatic ; and if I make a few apparently definite assertions, it is only by way of expressing such judgment as I have been able to form at present, and they are to be taken as intended more by way of suggestion and question than anything else.

With this proviso I should be disposed to make some such statements as the following :

51. All parts of a lightning-conductor, from points to roots, should be of one and the same metal, to avoid voltaic action.

52. Joints should be avoided when possible, and should be made substantially when necessary. Allowance for expansion and contraction must not be forgotten.

53. Sharp bends, and corners, and curves, and roundabout paths to earth should be avoided as far as possible.

54. The use of copper for lightning-conductors is a needless extravagance.

55. Iron has advantages over every other metal.

56. The shape of cross-section is but little matter. Flat ribbon has a slight advantage over round rod, but not enough to override questions of convenience.

57. Liability to be deflagrated by a powerful flash determines the minimum allowance for size of cross-section. No consideration of conductivity and greater ease of path has the least weight in this connection.

58. It is hopeless to pretend to be able to make the lightning-conductor so much the easiest path that all others are protected. All possible paths will share the discharge between them, and a lot of apparently impossible ones.

59. A good and deep earth should in general be provided, independent of water and gas mains.

60. If the conductor at any part of its course goes near water or gas mains it is best to connect it to them.

61. If the place to be protected has water or gas pipes inside it, the conductor should be connected to their mains underground.

62. At all places where water and gas pipes come near each other, and, in general, wherever one metal ramification approaches another, it is best to connect them metallically.

63. The neighbourhood of small-bore fusible gaspipes and indoor gaspipes in general should be avoided in erecting a lightning-conductor.

64. Into powder magazines and such like places no gas or water pipes should be permitted to enter, unless the whole building is made of metal, and they are elaborately connected to it at the point where they enter.

65. It is not wise to erect very tall pointed rods above the roof of a building.

66. A number of points all along the ridge of a roof is better than only a few.

67. Any part of a building is liable to be struck, and, to make quite secure, every prominent part of the outside should have a rod running along it.

68. Earth-connected as well as insulated bodies are liable to spit off sparks.

69. No complete security can be attained unless the whole building be metal-lined, floor and all.

70. In ordinary houses it may be well to try and insulate the lightning-conductor from the walls so as to lessen the chance of side flash to metal stoves and things inside.

71. In chimneys it may be well to use insulators to protect the bricks from concussion.

72. The cheapest way of protecting an ordinary house is to run common galvanised iron telegraph wire up all the corners along all the ridges and eaves, and over all the chimneys, taking them down to the earth in several places, and at each place burying a load of coke. Rain-water spouts and other outside metal, if all well connected together, may likewise be utilised.

73. Connecting a lead roof or other such expanse with a lightning-conductor is not an unmixed good, for it virtually increases the dangerous proximity of the lightning-conductor, and may inadvertently bring it near to many objects which else might have escaped.

74. One of the most difficult things is to know what to connect and what to avoid.

75. The orthodox rule, "Connect all pieces of metal to the lightning-conductor," requires modifications, thus : connect all pieces of metal to each other and to the earth, but not to the lightning-conductor.

76. It may be always reckoned safe to earth things independently. It is often not safe to connect them to the lightning-conductor : *e.g.*, an inside lining of a chimney should be well earthed, but should not be used as lightning-conductor, nor connected with it. The same with rain-water pipes and gutters. The same, also, probably, with lead roofs.

77. In connecting pieces of metal to each other, if they happen to form a nearly closed circuit, the circuit should be metallically completed.

78. Over the top of tall chimneys it is well to take a loop or arch of the lightning-conductor, made of any stout and durable metal.

79. Lightning-conductors should be always outside and easily visible.

80. A conductor detached from the building to be protected is safer than one in close contact with it.

81. For powder magazines and such like an outer cage surrounding the building, with sky points and earth roots, and an inner case on the building, with independent earth terminals only, is the safest plan.

82. If under these circumstances there be no gaspipes nor much ramifying metal work inside the building, and no metal at all going near either cage, the interior may be considered perfectly safe.

83. The inner cage may often be conveniently made of continuous sheet-iron. The outer cage need not then be at all small-meshed ; in fact, it need be little more than a dozen vertical conductors.

84. The resistance of an earth may be tested in the customary way to guard against actual breaches of contact by rust or workmen ; but no overweening confidence must be felt, even though the resistance turn out the thousandth of an ohm or less.

85. A Wimshurst machine and couple of Leyden jars afford a convenient mode of testing a conductor for flagrant defects. The testing should be done in the dusk or in moonlight, so that there may be light enough to work by, and yet sparks be visible.

86. Telephones are the handiest things to detect electric surgings in conductors inside the house while discharges are being made to the conductor. But vacuum tubes, gas leaks, Abel's fuses, etc., can also be employed.

87. Another mode of testing can be carried out on an insulated rod, with an induction coil and spark gap after the manner of a great Hertz oscillator. This is probably the most searching plan. Sparks will then be probably obtained from all the gas-brackets, water-taps, and picture-rails in the house.

88. Telegraph stations, and houses supplied with electricity from overhead wires, should have an efficient lightning-protector at the place where the wires enter the house.

89. When a number of houses are wired up together for lighting, even by undergroun wires, it may be well to disconnect them by means of intervening lightning-protectors on the principle of fireproof doors.

90. A central lighting station, having a tall chimney connected to its boilers and dynamos, should be, by a lightning-protector, disconnected from the leads which carry the current from it ; because a small fraction of a stroke getting into the leads might destroy a number of lamps, especially if they were already working at something like their full power.

91. Telephone arrangements, and any long length of close-packed insulated wires (even underground) should be protected by lightning-protectors, else the insulation is apt to be sparked through and spoiled.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence ; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

Although the Paris Exhibition is open, the major portion of the exhibits are in so backward a state that any systematic description is almost impossible at present, so we shall wait a short time till the chaos of packing cases becomes a neat arrangement of exhibits. It is needless to tell our readers that—so far as our description of the electrical exhibits is concerned—our attention will, in the first place, be directed to the interests of English and American exhibitors. A special edition of this paper, with the report of the exhibition in two languages—English and French—will be obtainable in the Exhibition.

MAJOR MARINDIN'S REPORT.

Major Marindin must be congratulated upon having so soon issued his report upon electric lighting in London. In another column will be found the conclusions he has come to, together with a letter from the Board of Trade to the Chairman of the London County Council. The report strikes us as an admirable common-sense affair, overcoming the difficulties of the situation by accepting them and making the best possible face upon the matter. Broadly speaking, the report suggests that things should be left pretty generally as they are, and that companies who have obtained sites and arranged areas should retain those areas. Criticism upon this report must be somewhat unsatisfactory till the model provisional order, based upon it, is ready. This model order is promised by the Board of Trade as early as possible. It will be the order that will regulate the practical details of metropolitan work, and will tend to make electric lighting a success or a failure.

It will be well, however, to point out the salient features of Major Marindin's conclusions, which we are glad to see partake very much of the nature and character of those we have from time to time promulgated. In the first place, he thinks the local authorities should be consulted, and their opinions deferred to as much as possible, leaving the loophole that if these opinions are clearly obstructive and founded upon no good reasons they may be ignored. Our readers well know our contention all along has been that the local authorities must know better than any central body what their special district requires, and it is hardly within the bounds of practical local government that annually elected representatives will prove wilful obstructionists. If electric lighting is to progress, it will not be by running counter to local ideas ; and we trust that the Board of Trade will have no occasion to be brought into antagonism with any local body, because the latter objects on "general grounds."

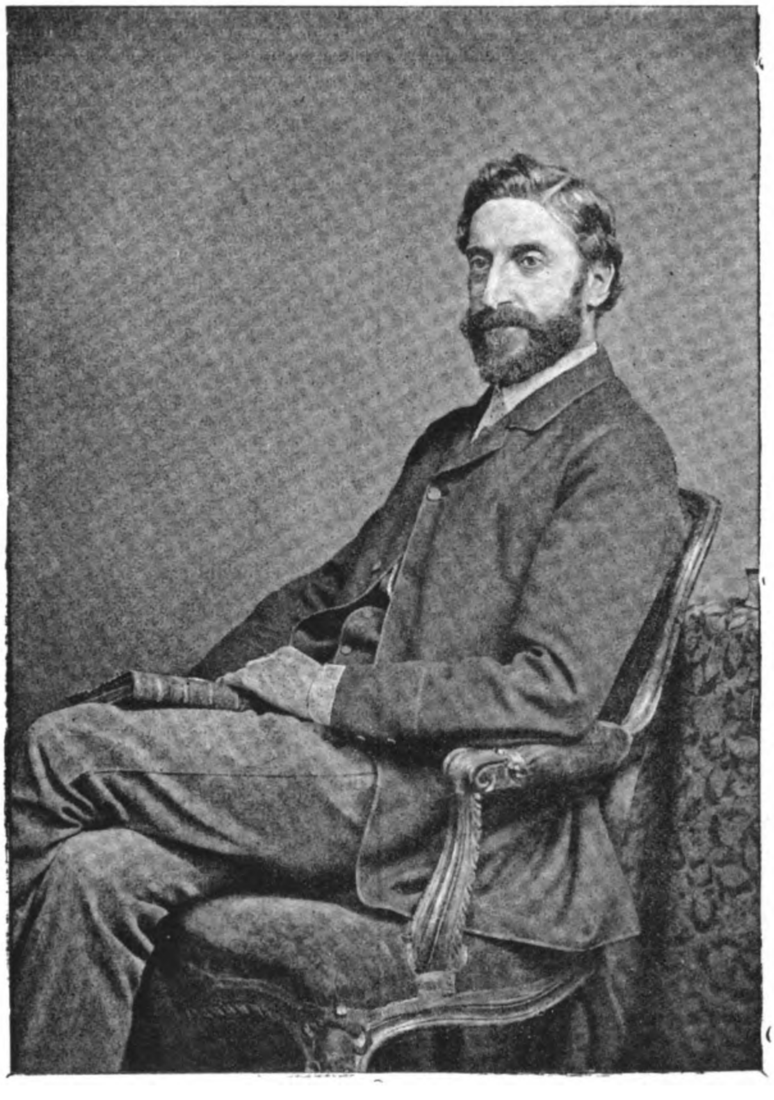
The fixing of a maximum price and the revision of this price periodically is not so important as many may deem at first sight. The electric lighting industry is not without a competitor. From a business point of view there seems no possibility of its ever being left in the position of a monopoly, and therefore those engaged in the financial branches of the industry will be unable to impress what price they please. The charges will naturally be such as will enable good work to be done, and a fair return made for the capital expended. The lighting must increase against competition with gas, and for years prices will be somewhat regulated by such competition till, even if the whole City is electrically lighted, prices will have no chance of being raised. It will be seen that our opinion differs somewhat from that expressed in the report which says, "The competi-

Digitized by Google

tion with gas, which at present at any rate, and probably for many years to come, will appeal to a totally different class of customer, will not be nearly so effective, while the potential competition from the power of calling in a new company in an area badly served is not likely to be called into play until the bad service has passed through many degrees, and has reached a very low ebb indeed."

When we first read the report we thought the phrase, "That in the abstract, competition is desirable," would be followed by one "That in the concrete it would be found impracticable," but, on the contrary, while the latter may be read between the lines it is not so definitely stated, and the weakest point in the report suggests that competition in the same area may be allowed when limited to two different systems. Would this conclusion have been different if Messrs. Ganz had been six weeks or six months earlier with their alternate current motor, for the reason given for this competition is that power cannot be distributed by alternate current systems. A previous paragraph militates against the weakness of this suggestion, in that where two companies possess powers over the same area "different streets should be scheduled for each." This seems to mean, while permitting competitors into the same area, nominally they are really to be kept in distinct sub-areas. The result, if permitted, will be costly, with no benefits accruing either to consumers or shareholders. We except the case as totally distinct where one company requires running powers only through the district of another company. At any rate, if the alternate current motor is commercially practicable, Major Marindin's reason falls to the ground, and likewise his conclusion, hence we may take it that the condition, one company, one area will prevail.

The period limiting the use of pioneer overhead wires is two years. This should meet the approval of the various companies interested. The remainder of the report deals with the distribution of areas among the existing companies. It is not within our province to discuss this distribution, the companies having fully presented their views, and no doubt each competitor has felt grateful on some points, and dissatisfied on others. This report, at any rate, will, for the time being, clear the air, and the various powers given will enable the companies to get to work. They have been waiting long enough. Once get to work without fear of legal tinkerings or alterations from the Board of Trade or any other authority, the real progress of electric lighting will depend upon the manner in which the work is carried out, and the arrangement of the details governed by the model order. The companies in the field, so far as we can gather, are determined to leave nothing undone to ensure success. May they obtain it, and London become, as it should be, the best lighted city in the world.



JOHN HOPKINSON, F.R.S., D.SC.

JOHN HOPKINSON, F.R.S.

Among the quartet of vice-presidents of the Institute of Electrical Engineers, not the least renowned is Dr. John Hopkinson. In the ordinary course of events we may expect Dr. Hopkinson to be our next president, if, as we assume, the election is by seniority. Few members of the Institute have contributed more scientifically accurate information to the world than Dr. Hopkinson. Like a few other men, he goes to the very root of the questions he takes up, and the results at which he arrives stand the test of the sharpest criticism. Dr. Hopkinson is a Lancashire

Digitized by Google

man, born at Manchester in 1849, the eldest son of Mr. Alderman Hopkinson. His mother is a daughter of the late Mr. John Dewhurst, of Skipton. The rudiments of his education were obtained under Mr. C. Willmore, at Linden Grove School, and subsequently at Queenwood College. In his sixteenth year he went to Owens College, where he remained for two and a half years, and then went to Trinity College, Cambridge. In 1871 he was senior wrangler and Smith's prizeman. It is often said that few senior wranglers make their mark in the world, but we believe this statement is the result of ignorance. It would be easy to give name after name of those who, having achieved this distinction, and having cast aside the scholastic for the practical work of the world, have obtained a position at the head of the profession adopted. Dr. John Hopkinson is a proof of this so far as the electrical engineering profession is concerned, and we might cite the names of Moulton among lawyers, and Sprague among actuaries, in support of our contention.

While at Cambridge he graduated at London University, where he took the D.Sc. degree. Following the axiom that "all work and no play, etc.," he paid a moderate attention to athletics, rowing in the college eight, and as a ped., travelling the mile sufficiently well to win a race just before the tripos examination. In 1872 he joined Messrs. Chance and Co., near Birmingham, as their engineer. This firm stands prominent as producers of optical apparatus for lighthouses. Dr. Hopkinson resided in Birmingham about six years, and then removed to London. He has introduced many improvements into lighthouse apparatus, notably the group flashing apparatus, and has been uniformly successful in all his designs, which now probably exceed, so far as special signs are concerned, in number those of any other engineer. Upon his removal to London, besides his special work, he commenced general practice as an engineer, and has since then devoted very careful attention to electrical engineering. His work in connection with dynamos has been very important. In his paper before the Mechanical Engineers in 1879 he first introduced the methods of graphically depicting certain phenomena by means of characteristic curves. The use of these curves has become as common and as useful in dynamo work as indicator curves are in engine work. Early in 1883 he made improvements on the Edison machine, and in conjunction with his brother, Dr. Edward Hopkinson, these improved machines have been constructed by Messrs. Mather and Platt. Some exceptionally valuable work has been brought forward in lectures or papers read before the Institution of Civil Engineers, and the Institute of Electrical Engineers. Dr. Hopkinson was elected a member of the Royal Society in 1878.

SECONDARY BATTERIES.*

BY J. APPLETON.

(*Concluded from page 400*).

Unfortunately, however, as in other things, what is theoretically perfect in secondary batteries is often practically bad. It is obvious that a plate of this type cannot discharge at such a rapid rate as a Crompton-Howell or E.P.S. plate, and this is a great disadvantage, especially in the work that the secondary battery will have to do in the future. The internal resistance is also comparatively high, owing to the very small surface of contact. It is possible to make a solid peroxide plate so dense, and therefore mechanically strong, that its life will be comparatively long, but then the capacity is sacrificed, and, on the other hand, a plate of wonderful capacity can be made, but unfortunately it is very fragile, and dies early. Here is a piece which has shared this fate. Another great difficulty to be overcome with this type of plate is the contact. Platinum is expensive, and must be used sparingly, and it is by no means an easy job with an unlimited quantity of platinum to make a good and lasting contact. It is possible to obtain a few discharges without any difficulty, but sooner or later the contact becomes coated with a film which increases the resistance. I mention this type of plate, as I think in this direction endeavours will be made to produce a battery which has no local action and will not require to be overcharged to keep it in good condition.

I have here samples of a new material for making battery-box linings, a little description of which may be of interest to you. [Several linings shown] It is perfectly acid-proof, and can be worked up into any desired shape. By slightly heating it can be bent or moulded, and retains the shape when cold. The joints are not merely stuck together, but the surfaces are dissolved with a solvent, and under pressure they unite to form practically one solid piece. It is a splendid non-conductor, and is admirably suited for this work.

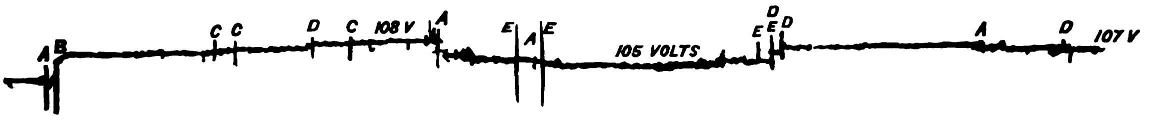
Another direction in which work has been done is to produce an accumulator with an alkaline solution and strong metal plates. This has been done, with great success apparently, by Messrs. Commelin and Desmazures, in France. They use a copper plate made of compressed copper opposed to a plate of iron-wire gauze in a solution of zincate of potassium. During the charge zinc is deposited on the iron gauze, and the oxygen absorbed by the copper plate. In the discharge the zinc is dissolved, combining with the oxygen from the copper plate. A very high discharge is obtained from these cells. A box containing three cells weighs 28lb., and gives a discharge of 150 ampere-hours at about 2·5 volts. The E.M.F. of these cells is low, under

* Paper read before the City and Guilds of London Old Students' Association at the Technical College, Finsbury, on Wednesday, May 8.

Digitized by Google

one volt, but there are advantages which more than compensate for this. One very peculiar feature in this battery is that the shaking, such as is met with in tramcar work, is advantageous rather than otherwise. There are many advantages in a cell of this type; for example, a thin metal box is all that is required, no glass or acid-proof linings being necessary. Again, for tramcar and portable work the absence of acid is a great boon, the alkaline solution being comparatively harmless to surrounding wood and metal work.

the negative plate, and reduces the efficiency of the cell. The diagrams shown are facsimiles of E.M.F. curves taken by a recording voltmeter. They are from a large set of 31 L cells, which are charged by a dynamo driven by a gas-engine. When the cells are in use this voltmeter is started, and it records the exact E.M.F. at the terminals of the cells during charge and discharge. You will see how sensitive and accurate the instrument is, and what a valuable record is kept. This instrument is designed by Messrs. Reginald Jones and J. E. Hall, and is



CHARGING SECONDARY BATTERY; CURVE OF E.M.F. BY RECORDING VOLTMETER.

Begins Charging at 107 volts. A, Cell put in; C, Miss fire of Gas-engine; D, Cell taken out; E, Battery circuit broken; B. Engine stops. After A, at left hand, lights from Cells only.

The maintenance of secondary batteries is not difficult when a slight knowledge of the behaviour of the cells is obtained, and if a sharp look out is kept for faults so that they may be remedied before getting too serious. The following remarks on the maintenance of batteries refer chiefly to cells of the E.P.S. type, as they are the only type with which the electrical engineer has to do at present. In charging a new set of cells for the first time it is very important that the charge should be commenced at a slow rate. Some of the cells will need more charging than others, and the charging should be continued till the electrolyte becomes quite white or milky with the gas that is given off. It will not hurt the cells that get to this state first to continue the charging till all the cells are alike, provided the charging current is not too great; if, however, one or two of the cells are much behind the others, it will be advisable to cut them out during the discharge, joining them up again for the next charge. One thing I have found in new cells that should be carefully watched. If any little drops of lead have fallen while burning the lead lugs, and have lodged on the plates, they should be removed; if this is not done they will cause trouble. The condition of a cell can be accurately ascertained by use of the hydrometer, and it is very useful to prepare a table showing the fall in specific gravity of the electrolyte for a given number of ampere-hours taken out of the cell. Care must be taken that the acid density is the same throughout the whole of the electrolyte, or the bulb of the hydrometer may be in a denser part of the electrolyte, and therefore give a higher reading than is correct. The tendency is for the acid to become denser at the bottom of the cell, and this should be prevented by occasionally blowing up the electrolyte with an indiarubber ball or piece of glass tube. If the cells are always charged to gassing, this will not be so necessary. Each cell in a set should be periodically tested with a voltmeter reading to about three volts; this should be done during the discharge, and it will show whether every cell is doing its share of the work. This is also the best way of finding out short circuits, and if the cells are tested when the discharge is nearly completed, it will show which are working up to their full capacity and which are not. A sharp look out should be kept for any appearance of white sulphate; it is easy to get rid of just a little here and there; but when the cell is badly sulphated it requires careful treatment. If a cell is charged at a fast rate when in this condition, gas will be given off from the lead grids instead of oxidising the active material, which is clogged up or coated with the sulphate, and some of the plugs may be forced out. By charging a cell slowly for a long time it is possible to get rid of this sulphate, and as much as possible should be scraped off during the charge with a piece of ebonite, so that the surface of the active material may be exposed to the electrolyte.

Mr. Barber-Starkey has tried with very great success the use of carbonate of soda in the electrolyte to prevent sulphating. He has a set of cells for lighting, which are never charged at the proper rate, and very seldom fully charged, owing to the insufficient engine-power, the current being about 10 amperes instead of 25 amperes. These cells got into a very bad condition in about three months after they were put down, so he put into each cell a handful of common washing soda. They soon got into good condition again, and ever since he has had no trouble whatever with them. They can be left for several months without charging, and are never charged beyond the gassing point. It is now about three years since this was tried, so there has been ample time to test the efficiency of this method. The peroxide plates are in a beautiful condition, and the cells altogether are in as good a condition as when new. This plan has been tried in several places since with great success. It removes two of the greatest objections to cells of this type—viz., the overcharging required, and the impossibility of letting the cells remain idle. If the cells can be cut off directly gas is given off, a great gain in efficiency is effected, as the E.M.F. required to charge them rises slowly as the capacity increases to about 2·1 volts, when gas is given off, and the E.M.F. rises rapidly to about 2·4 or 2·5 volts. This increase of ·4 volt per cell is entirely wasted in overcoming the E.M.F. due to gas on

somewhat on the same principle as the recorder used by Mr. Wright at the Brighton central station. It is manufactured by the Woodhouse and Rawson Electric Supply Company.

Of course, cells should never be discharged at too fast a rate. This will cause the plates to buckle, and the plug of active material to fall out. Buckling, in some cases, is due to the plates being badly constructed, and to their being supported or held in the wrong places. These are the chief points to be remembered in the maintenance of secondary batteries, and I hope you will pardon me if I have been saying things which are already well known to some of you. In secondary battery work especially it is impossible to learn much by reading books or studying chemical formulæ. Experience must be gained by carrying out the actual work, and watching the results of the actions which take place.

Although it may appear to be very easy and simple, yet in carrying out experiments, and trying new ideas, one meets with results which are very misleading and difficult to reconcile with theory. I have endeavoured to put before you some of the lessons which experience has taught me, and I hope they have been in some degree interesting.

ELECTRIC LIGHTING IN LONDON.

The following letter and extracts relate to the Board of Trade Enquiry into Electric Lighting in London. They speak for themselves:

Board of Trade (Railway Department),
London, S.W., May 18.

My Lord,—I am directed by the Board of Trade to transmit to you the enclosed copies of Major Marindin's report made after his enquiry, held by direction of the Board of Trade, into the various applications for provisional orders and licenses under the above-mentioned Acts in respect of the metropolis, as well as into the subject matter of a Bill introduced into the House of Commons by the Metropolitan Electric Supply Company, Limited.

In forwarding copies of this report for the consideration of the County Council, I am to inform you that, subject to any observations that they may wish to offer, the Board of Trade propose to adopt the recommendations of the report with regard to the allocation of the various districts to the several companies.

A description of these areas will be found in the report, from which it will be seen that in the following districts only powers over the same area are proposed to be granted to more than one company—viz.:

St. George's, Hanover-square.

A small portion of the parish of Lambeth to the north of Westminster-bridge-road.

A small portion of the parish of St. Martin's-in-the-Fields to the east of Northumberland-avenue and St. Martin's-lane.

The Board of Trade concur in the opinion expressed by Major Marindin, that looking to the fact that the supply of electricity on the alternating current and transference system cannot be made use of for motors, the competition of a system which can be made useful for motors is desirable, and that, consequently, where powers are granted within the same area to two companies both those companies should not be those using alternating currents. This principle has been adopted in allocating the various districts, except in so far as regards a small portion of the parish of Lambeth to the north of Westminster-bridge-road, which has been allotted to the London Corporation and the Metropolitan Company, both of which propose to use alternating currents and transformers.

The latter company was the only one which proposed to take the whole of the parish, and they are in possession of a site for a generating station in the northern corner of the parish. The whole of the parish was, therefore, allotted to this company, but it was found necessary also to grant powers to the London Company over a portion of the parish in order to give access to the districts allotted to it on the other side of the Thames.

A small portion of the parish of St. Martin's-in-the-Fields has been allotted to the same two companies; but in this instance the latter company possess a generating station in Whitehall-place, from which the supply is by a continuous current.

In two of the parishes allotted to the London Company—viz.,

Digitized by Google

Chelsea and St. James's, Westminster—powers to supply electricity have already been granted to other companies by provisional order and license granted in the years 1886 and 1888 respectively. Both of these companies, however, use continuous currents.

In the present orders it is proposed to substitute for the provisions as regards Schedule A and Schedule B, hitherto usually adopted, a provision that the undertakers should be bound at once to lay down mains in certain streets to be scheduled, and that they should be compelled to lay mains in any other streets in the area on requisition by owners or occupiers.

With regard to the question of capital, I am to point out that, while the capital of the various companies would doubtless be wholly inadequate if the entire areas allotted to them required to be lighted at once, they possess, in the opinion of the Board of Trade, sufficient capital to provide for all the work they are likely to be called upon at present to perform.

As regards the maximum price chargeable, the Board of Trade, in the absence of any evidence that such a price would be excessive, propose to adopt the maximum of 8d. per Board of Trade unit. They think, however, that a clause should be inserted providing for a revision of the terms of charge at the end of seven years from the date of the order, and they propose that this clause shall be so drawn as to make it possible to adopt, as regards electrical lighting, the principle of the sliding scale of charge, which has been applied with advantage under the Gas Acts. It is impossible at present to foresee the initial price which it will at the end of that period be reasonable to prescribe; but, following the analogy of gas, and considering that the electric companies only have a certain tenure of 42 years, the Board of Trade are of opinion that a price arranged on the basis of a 10 per cent. dividend would not be unreasonable.

With a view of saving time, the Board of Trade are now going through all the objections raised to the clauses of the orders, and are preparing a model order, which, with the necessary variations for the varying circumstances of different districts, would be adopted for the whole of the applications, and that, as soon as this model order is in a sufficiently advanced stage, a copy will be forwarded to the County Council.

In conclusion, I am to state that as time is of the utmost importance, the Board of Trade would be glad to be favoured with the observations of the London County Council at their earliest possible convenience.

I have the honour to be, my lord, your lordship's obedient servant,

HENRY G. CALCRAFT.

The Earl of Rosebery, London County Council, Spring-gardens.

MAJOR MARINDIN'S CONCLUSIONS AND SUGGESTIONS.

(1) That it must be admitted that the science of electric lighting has now reached the point at which a supply can be made which will be of very great benefit to the public, and that the power of obtaining this supply should be within the reach of all persons who may require it. For this reason it seems to me that although the wishes and opinions of the local authorities in the areas proposed to be supplied should be consulted and deferred to as far as possible, the mere objections by a local authority to the introduction of a company proposing to supply electric light upon general grounds should not be considered sufficient to exclude such company, unless the local authority should express its intention to undertake the supply, and give evidence that it proposes to apply for permission to do so, and this should apply with more force when it can be shown that the exclusion of a company from such an area would injuriously affect the service of other contiguous areas.

(2) That in dealing with this question it should be considered as one affecting the interests of the metropolis as a whole, and as an area which at no very distant time may be for purposes of lighting and management of roads and streets under the control of one central authority; and that therefore the whole of the provisional orders granted for the metropolitan area should, as far as possible, be identical in form, with identical provisions as to supply, compulsory powers, interference with streets, and, more than all, as to price.

In my opinion the scheme adopted in 1883 of dividing the area of supply into two areas, A and B, would not be likely to work so much to the advantage of the public as the proposal in most of the orders under consideration to make the supply compulsory under requisition over the whole area upon equal terms.

I consider, however, that in order to ensure that some work shall be at once undertaken in every parish or district within the area of supply under such order, there should be a list of streets scheduled for compulsory laying of mains, and a deposit made in every case where the local authority may wish to have it.

Where there are two companies in the same area, different streets should be scheduled for each.

With regard to the clauses affecting supply, interference with streets, testing, position of stations and distributing boxes, and other details, the whole of the suggestions made by the local authorities should be carefully weighed, and those which are considered necessary embodied in the model form of order.

With regard to price, I do not consider that any one district in the metropolis should be put in a better position than another.

Taking the area as a whole, it does not appear that it would be wise to fix a lower maximum than 8d. per unit.

It is true that the London Company is now supplying at 7½d., and the maximum in the St. James's and Pall Mall Company's license is 7d., but these companies are competing in an exceptionally good area.

There would, however, appear to be a necessity for a reduction of the high rate for minimum supply, that is, the sum which every customer taking a supply can be called upon to pay, irrespective of the amount which he has consumed, and which in the orders varies between £3. 6s, 8d. per quarter in the case of the Notting Hill Company, and £5. 10s. in the case of the Metropolitan Company's South London order.

The latter company has consented in the Mid London and West London orders to reduce the minimum to 13s. 4d. per quarter, and I consider that whatever minimum is fair should be adopted throughout.

The provision for revision of price after each seven years, in the agreements between the Metropolitan Company and the Strand and Marylebone local authorities, seems to me to be somewhat contrary to the policy of Parliament when dealing with the Electric Lighting Act. If any such provision be inserted it should be general; and it would appear to be more fair that the revision should take the form of a sliding scale upon the basis of a 10 per cent. dividend, the standard being fixed after the experience gained by the working of the first seven years.

It has been suggested that in the matter of price the consumer should, if he elects himself to pay the whole cost of connecting his house to the mains, have no minimum at all imposed upon him; but, although I can see no objection to this proposal, such a provision would hardly be necessary where the minimum is reduced as in the metropolitan orders.

(3) That in every case the supply of electricity, whether by a company or by a local authority, should be under statutory obligations as well as statutory powers, by means of a Bill, a provisional order, or a license.

(4) That there is no objection to the granting of a large area of supply to any company which shows that it has sufficient capital and is capable of coping with the demand. On the contrary, a large and rich company is likely to be the best and most economically managed concern, to be able by working over a large and scattered area to develop the demand for the light, and by rapidly increasing its business to be the sooner in a position to reduce the price of the article supplied.

(5) That in the abstract competition is desirable, as tending to keep down the price, and to cause the manufacture and supply of electricity to be carried on with all the attention and energy which it is possible to devote to it.

The competition with gas, which at present at any rate, and probably for many years to come, will appeal to a totally different class of customer, will not be nearly so effective, while the potential competition from the power of calling in a new company in an area badly served is not likely to be called into play until the bad service has passed through many degrees, and has reached a very low ebb indeed.

The question as to how many companies should be granted concurrent powers in one area requires more consideration.

In cases where the local authority objects to the entrance of any company, and it is decided to overrule the objection, I think that one company should only be granted powers.

In cases where two or more companies have obtained the assent of the local authority, the following facts must not be lost sight of:

1. That the laying of the mains of several companies up one street means so much dead capital, and, moreover, the provision of a certain amount of useless material, which the local authority would have to pay for if it should decide to purchase the undertakings after the lapse of 42 years.

2. That no matter what regulations or stipulations may be made as to the laying of mains, the interference with the streets, and the consequent inconvenience to the public, must be in a certain degree proportionate to the number of companies having powers over these streets.

For these reasons, I am of opinion that, for the present, powers should not be given to more than two companies over the same area, and, inasmuch as the companies supplying under the alternating current and transformer system cannot supply electric energy capable of use for motors, that both of these two companies should not be those using this system.

In order, therefore, to leave room for the entrance of a direct supply company into an area where two alternating current transformer companies have been assented to, it will be necessary to choose one only of these companies, and this will lead to a certain amount of districting.

(6) That wherever a company now supplying a district by means of overhead wires is granted an order for such area, it should be placed under the obligation to remove these overhead wires within a period of two years from the granting of the order; and, if such a thing be possible, that this company should be prevented from invading a district in which it has not got powers by means of overhead wires.

(7) That in order to reduce as much as possible the disturbance of streets, clauses should be drafted making it obligatory for companies to lay their mains in existing subways, and to transfer them into subways which may be made in the future upon being called upon to do so.

If possible, it would also be advisable to provide that wherever circumstances admit of it, and where there is no subway, the conduits put down to lay the mains should be made capable of accommodating the mains of both companies in the area, if there be two companies having powers therein.

To a certain extent, also, it would appear to be right that the local authorities should have the power of objecting to the sites for generating, as distinguished from distributing stations, subject to an appeal to the Board of Trade.

Applying these principles to the orders asked for by the several companies, I recommend the Board of Trade to adopt the following course in each case:

I. The London Electric Supply Corporation.—As this company and the Metropolitan Company are competing in many parishes and districts, and are both companies working with alternating currents, unable at the present time to provide for motive power, the areas applied for should be districted, and I propose, therefore, to allot to

Digitized by Google

the London companies and to include in the London order the following parishes and districts :

The portion of St. Martin-in-the-Fields lying to the south of the Strand and west of St. Martin's-lane ; the portion of St. Margaret and St. John, Westminster, lying to the north of Victoria-street, excepting that portion of St. Margaret's lying to the west of St. George, Hanover-square ; St. James, Westminster ; St. George, Hanover-square ; Chelsea ; the Greenwich district ; St. Mary, Rotherhithe ; St. Mary, Bermondsey ; the district of St. Olave ; the district of St. Saviour, Christchurch ; and that portion of St. Mary, Lambeth, lying to the north of Westminster-bridge-road.

The only dissenting local authorities in the above areas are the Vestries of St. James, Westminster, of St. Mary, Lambeth, and of St. Margaret and St. John, Westminster, and the District Board of St. Saviour's, but of these the first two would, judging from the statements of their representatives at the enquiry, consent, if their objections be, in the opinion of the Board of Trade, fairly met ; and it should be pointed out to them that, while St. James's would under the terms of the order gain by the compulsory removal of the overhead wires with which the London Company is at present largely supplying in the parish, it is in the case of St. Mary, Lambeth, essential to the continuity of the London Company's area that this company should have the means of passing through the northern end of the parish.

This last reason applies equally to the parishes of St. Margaret and St. John, and the opposition of the united vestry of these parishes was not so strong as to lead to the belief that it would object to the division of the parishes as I propose between two companies, especially as there appears to be a demand for electricity in the district.

The district of St. Saviour's, after assenting to the granting of the order, withdrew the assent, but did not appear at the enquiry to give any reasons for so doing, and as the district intervenes between other portions of the London area, the local authorities of which have assented and wish for the supply of electric light, I submit that the objection of St. Saviour should be overruled.

The case of St. James and St. John, Clerkenwell, is difficult to deal with. This parish is cut off from the district which I propose to allot to the London Company, and the Metropolitan Company has abandoned the North London order, in which it was included, while the Vestry has assented to the entrance of both companies.

If the City should consent to allot a district to the London Company, giving access to Clerkenwell, this parish should be added to the London area, otherwise it might be suggested to the Metropolitan Company to adhere to their North London order so far as this parish is concerned.

The general form of the clauses of the order should be similar to those in the other orders for the metropolitan area, and it will be better to deal with all the suggestions and requirements of the local authorities on this head generally, when the principles upon which the orders are to be granted have been considered and determined ; but there are two special clauses in the London order which have already been alluded to, and might be dealt with separately.

I do not see any objection to clause 55, authorising the supply to a local authority of electricity in bulk, provided, in the opinion of the legal authorities, it be possible to place the local authorities under the obligations of the order by any such clause.

As to clause 56, I think that, subject to the subdivision of the generating station at Deptford, as recommended on page 19 of this report, it would be a mistake to reduce the cubical dimensions of the building.

A compliance with the recommendations on the above-mentioned page should be a condition upon which the granting of the order should depend.

II. The Metropolitan Company.—To this company I would recommend that the following area should be allotted :

Under the Mid-London Order.—St. Giles-in-the-Fields ; St. George, Bloomsbury ; St. Andrew, Holborn-above-Bars ; St. George the Martyr ; St. Sepulchre ; Saffron-hill ; Hatton-garden ; Ely-rents and Ely-place ; the Liberty of Glasshouse-yard ; St. Ann's, Soho ; St. Paul, Covent-garden ; St. John the Baptist ; Savoy or precincts of Savoy ; St. Mary-le-Strand ; St. Clement Danes and the Liberty of the Rolls ; together with the extra-parochial places known as the Charterhouse, Gray's-inn, Lincoln's-inn, Staple-inn, and Furnival's-inn.

The whole of the local authorities in the above area assent to the order.

Under the West London Order.—St. Marylebone, the vestry of which assents to the order.

Under the South London Order.—St. Mary, Lambeth, St. Leonard, Streatham, and Clapham.

Neither of the local authorities affected—viz., the Vestry of St. Mary, Lambeth, and the Wandsworth District Board—has signified its assent, but both would probably do so if their objections be met in a manner considered fair by the Board of Trade.

Under the Bill.—That portion of St. Martin-in-the-Fields which lies to the east of Northumberland-avenue, Charing Cross, and St. Martin's-lane.

The Vestry of St. Martin-in-the-Fields assents to the Bill.

With powers in this area, the Metropolitan Company will have access from the main portion of the Strand district to the outlying portions, and will also have powers over some portion of the parish of St. Martin-in-the-Fields, contiguous to their existing station in Whitehall. In the latter portion, although the company will be competing with the London Company, there will not be two alternating current companies, as the supply from the Whitehall station is by continuous current.

The only area in which there will be two competing alternating-current companies is in North Lambeth, where it cannot well be avoided.

III. The House-to-House Company. IV. The Notting Hill Company.—I recommend that the areas as agreed to between these companies and the Vestry of Kensington be approved of and the orders granted in suitable terms.

V. The Kensington and Knightsbridge Company.—Similarly in the case of this company, I recommend that the area as agreed to between the company and the Vestry of Kensington be approved of and the order granted.

With regard to the part of the parish of St. Margaret, Westminster, applied for, I recommend that the order be approved of subject to the consent of the vestry. This body has decided to object to the powers which are being exercised under licenses granted by consent being extended to those given by provisional order ; but I trust that the matter may be so represented that this decision may on reconsideration be altered.

VI. The Chelsea Company. South Kensington Order.—This order is assented to by the Vestry of Kensington, and I recommend that it be granted for the area agreed to.

Belgravia Order.—In the case of this order I see no valid reason for dispensing with the consent of the vestry, which has been withheld. Consent has been given to the orders of three other companies.

VII. The Westminster Company.—Although the scheme of this company is in a somewhat incohate condition, the Vestry of St. George's, Hanover-square, has assented to the order. The Vestry of St. Margaret and St. John, Westminster, withholds consent ; but for reasons already given I consider that powers over part of the area asked for in this district should be given, the existing station of the company being in this area.

I recommend that the order be granted for the parish of St. George, Hanover-square, and the portions of St. Margaret and St. John, Westminster, lying to the south of Victoria-street. This company has abandoned the remainder of the area originally applied for.

VIII. The Electrical Power Storage Company. Paddington Order. In view of the objection of the vestry, and its expressed intention to undertake the lighting of the parish, and for other reasons given below, I cannot recommend that this order be granted.

St. Martin's and Strand Order.—The Vestry of St. Martin's assents, and the Strand District Board dissent to the order.

The company applying for these orders is a company manufacturing batteries and other electrical appliances, and it seems more than doubtful whether, under the articles of association, there is any power to undertake the manufacture and supply of electricity for house-to-house lighting purposes. However this may be, it is perfectly clear from the evidence of the manager of the company that the company does not intend to exercise the powers which would be granted by the order, but to transfer them to some other persons.

I have no doubt that these persons are perfectly willing and competent to carry out the powers and obligations of the order, but I submit that it would be quite contrary to practice to grant an order to any but a properly-constituted company, proved to be in a position to act under it, and as this has not been done, I cannot recommend that the order be granted.

It should be understood that in every case the recommendations to grant these orders is on the understanding that the whole of the works both at the generating and other stations, and along the mains, are to be planned and executed in a manner such as to satisfy the Board of Trade that the public are properly protected, both as regards safety, and, so far as may be possible, from any extinction of the light for an appreciable time, and that, should it be found impracticable to carry out the districting between the London and Metropolitan Companies in the manner which I have proposed, the whole question will be reconsidered so that the areas may be fairly readjusted.

The Metropolitan orders for the Strand and Marylebone should be in as nearly as possible the same form as those applying to other parts of the metropolis, as there does not appear to be any sufficient reason for treating these areas differently from any others.

The only districts applied for in which I have decided not to recommend the granting of orders, as amended, are the parishes of St. Pancras and Paddington, where the local authorities should, I think, be granted time to decide definitely whether or not to carry out the lighting of their parishes under the powers of a provisional order ; and the City, which, although not exempted from the operation of the Electric Lighting Acts, is in a somewhat different position from other parts of the metropolis.

The Commissioners of Sewers, acting for the Corporation, are endeavouring to obtain tenders for the lighting of the City, but I see no reason why the principle that all such lighting should be done under statutory powers and obligations should be departed from in their case.

If the Board of Trade should agree in this view, I would urge the Commissioners of Sewers to consider whether the orders, as remodelled, do not sufficiently provide for all their requirements, and in that case to consent to the division of the area of the City between the two competing companies—viz., the London and the Metropolitan Companies, the latter company being allotted the portion nearest to the Strand district, and the former the central and eastern portions of the City, so that access may be given to the parish of Clerkenwell, the vestry of which wishes for an order to be granted to this company.

In addition to the above-mentioned provisional orders, the two licenses applied for by the Chelsea Company and the House-to-House Company have to be considered. These licenses are both for areas included in the portions of the parish of Kensington allotted to the companies respectively by the vestry, and the consent of the vestry has been given.

Subject to any alterations in clauses which may be found necessary to make the provisions of these licenses similar to those of the provisional orders applied for, I can recommend that for the purpose of expediting the commencement of the works, they be granted.

I have the honour to be, Sir, your obedient servant,

F. A. Marindin, Major, R.E.

I concur with the above report. P. Cardew, Major, R.E.

SECONDARY BATTERIES.*

BY WILLIAM HENRY PREECE, F.R.S.

(*Concluded from page 373.*)

Central Stations.

The secondary battery lends itself admirably, under certain circumstances, to the economical distribution of electric currents from central stations. It is possible to lay down a long main circuit of small dimensions, conveying a direct current of high E.M.F., which at different points can charge a secondary battery of a small number of cells, so as to "transform" the dangerously high E.M.F. into one of a low and harmless character in the building to be illuminated. In fact, this is now being done in Chelsea by two different companies. The one company, the Chelsea Electricity Supply Company, is acting under the statutory powers of a provisional order, and it distributes its currents to the houses from sub-stations, where the batteries are kept and maintain a continuous supply of electric energy. Each sub-station, of which there are three, supplies current for 2,000 30-watt 10-c.p. lamps. There are 265 31-L cells, divided in two sets of groups of 53. Each set is charged separately and alternately in series from the central generating station. While one set is being charged the other is supplying currents to the consumer. The main charging current of 60 amperes has an E.M.F. of 500 volts per distributing station, or 1,500 volts for the present circuit; and the secondary discharging supply into the houses has a pressure of 100 volts. This system of distributing currents from batteries has many advantages. The currents, being direct, are available at once for motor purposes, as well as for lighting. The currents being so steady and uniform, add to the durability and life of the lamps. The supply being continuous day and night, it is always available, just as is the light from gas. The distributed currents being of low E.M.F., absolute safety to person is secured in such a system. The engines at the central station being always worked at full loads, can be worked under their most economical conditions; and as they can be worked continuously throughout the 24 hours, a minimum capital expenditure in engine plant is necessary. It has already been pointed out that the efficiency of the battery is not much affected by variations of its own load, and that whether one lamp or 100 lamps be used it is of not much consequence to the cells; in fact, the efficiency of the lighter load is the highest. On the other hand, it must be pointed out that there is a considerable capital outlay required in batteries. The depreciation of the cells is very considerable, and there is an appreciable loss of energy at each transforming point. The maximum efficiency of batteries in practice rarely reaches 70 per cent., while less than 15 per cent. for depreciation can scarcely be allowed with prudence. The batteries for 1,000 lamps cost £1,325, or 27s. per lamp. The reliability, constancy, and permanence of the light from batteries compensates for many another evil. The other company in Chelsea—the Cadogan Electric Supply Company—places the batteries in the houses, and charges 1,000 E.P.S. 31 L cells over a circuit of nine miles.

There is a central station in Detroit, in the U.S.A., also distributing by batteries, and giving great satisfaction.

The Kensington Court central station, established by Messrs. Crompton and Co., and that at Whitehall-court, also use secondary batteries, but the batteries are in the stations, and not in the houses. They are used more for regulation and for reserve force purposes than for distribution.

There is a large central station at Vienna, and one at Darmstadt of the same character.

An extremely ingenious mode of distribution has been proposed by Mr. Henry Edmunds. The battery is divided into four groups. Three groups are jointed in series, and supply energy to the house, while the fourth group is in the main being charged. These groups constantly and continuously changed places every three minutes by means of an automatic switch. A third of the battery is, therefore, always being charged, and this means that only one-third engine-power is needed at the central station, and only one-third of the E.M.F. on the changing main. Mr. Edmunds's automatic distributor is an extremely ingenious apparatus, but it has not yet received the test of practical trial, though the sooner it does so the better.

Traction.

A very important application of secondary batteries is that of traction. In the United States this system has received immense development, but in England it has scarcely as yet grown out of the experimental stage. In London the North Metropolitan Tramways are trying some important experiments, but in Birmingham an electric locomotive has been made by Elwell-Parker on the Julien principle, weighing 8½ tons, and worked by 100 cells, each weighing 81 pounds, which has drawn loads of 30 tons up stiff gradients, and has run 70 miles with only one charge. This system is destined to be most useful and economical, and it looks as though it would gradually replace horses for tram work.

Portable Lamps.

Two other useful purposes to which secondary cells are applied are (1) the construction of safety lamps for miners, and (2) reading lamps for railway travellers. Since one pound weight will give a capacity of four ampere-hours (and it is easy to obtain lamps which can be incandesced with only the third of an ampere), it follows that if we use three cells each weighing one pound, we can easily get a lamp which can be maintained alight for twelve hours giving a light of about two candles. This is ample for both purposes enumerated; in fact, I habitually travel with such a portable railway reading lamp, and find it of immense service. The battery that I am now showing to you was charged during the last Christmas holidays. I have not travelled since, and it has not lost much of its charge, as you plainly see. I have much pleasure in exhibiting several forms of safety miners' lamps, which have been lent me for the occasion by Mr. Pitkin, their manufacturer. Mr. Swan has done much in this direction, and his lamps are in considerable use, especially in South Wales, and are now exhibited in action.

Telegraphy.

All attempts to use dynamos direct for telegraphic purposes in England have failed, but their use indirectly, by means of secondary batteries, has been eminently successful. At the General Post Office, in London, there are 220 circuits thus worked from only 38 cells. The currents used for telegraphy are very minute compared to those used for electric lighting; ·05 ampere, or 50 milliamperes, is a large current for such a purpose. Thus the current that would light one 50-watt glow lamp will work 10 telegraphic circuits. The secondary cells are applied thus: 20 cells provide motive-power for Delany multiplex distributors, and 120 single needle circuits; 18 cells, or 2 parallels of 9 cells, provide currents for 100 direct inker Morse circuits.

This mode of working has now been in since the early part of 1884.

It is quite clear that the secondary battery has passed through the experimental stage, and that it has now reached its commercial career, where it will prove to be a most valuable and indispensable adjunct to the equipment of the electrical engineer.

* Paper read before the Society of Arts, May 1. This subject has been before the society on two occasions. In 1881 (vol. xxx., p. 30) Prof. Silvanus Thompson read a paper on the "Storage of Electricity"; and in 1883 (vol. xxxi., pp. 1,025, 1,038), Prof. Oliver Lodge, F.R.S., gave two lectures on "Secondary Batteries."

ALTERNATE CURRENT WORKING.*

BY W. M. MORDEY.

I wish to state at the commencement that this paper is not intended as a contribution to the comparison of the relative merits of alternate-current working, and of any system of direct-current supply. The discussion of this question has already taken place, and those who took the A.C. side have no reason to be dissatisfied with the result. It may, however, be pointed out that exclusive advocacy of any one particular method of working, as being the best for all purposes, is not a position that is likely to be taken by any electrical engineer who has any extensive acquaintance with the various requirements and conditions that are met with in practice.

Working Alternators Parallel, and Best Principles of Construction for Alternators.

This is a matter of very great scientific interest, and of still greater practical importance. It is not too much to say that the complete success of the transformer system of supply depends to a great extent upon whether alternators can be quite easily and successfully worked parallel. This has been strongly insisted upon, especially by the opponents of that system. The importance attached to it arises partly from the fact that the most economical method of supply is that of using always the smallest plant that will do the work, and increasing or decreasing the number of generating units in operation, according to the fluctuations of the demand. To do this most conveniently, the alternators should be worked parallel, and ought to be capable of being put in and out of circuit easily, and without causing even a momentary flicker or interruption of the light. The use of a large machine and engine for the small day supply is especially to be avoided. In almost all cases it is desirable to have a comparatively small set of plant for this work, even where large machines are used for the heavy evening work.

Another argument in favour of parallel working, as against the use of very large machines, is that it reduces the cost of the spare plant. Thus, if a station is provided with one or two machines and engines for the full load, the spare plant is equal in cost to the working plant, or, perhaps, to one half as much. If, however, smaller generating units are employed, one set in four may be considered a safe allowance.

The history of parallel working of alternators may be briefly sketched.

In 1868 Wilde described parallel working and synchronous action of generators, and so nearly obtained synchronous motor action that it is extraordinary he should have missed it.†

In 1882-3 Dr. Hopkinson,‡ not knowing of Wilde's work, arrived theoretically at the conclusion that it was possible to work alternators parallel, but not in series, and subsequently demonstrated the fact by trials made, in conjunction with Prof. Adams, on the De Meritens machines at the South Foreland Lighthouse, which were run parallel and as motors. This was all laid before this society at the time, and was very fully discussed.§

In the course of this discussion in 1884, Mr. Alexander Siemens described some experiments showing that the Siemens alternate-current machine ran as a motor.‖ This is interesting as being, so far as I know, the only recorded instance of an alternator without iron in the armature being run as a motor. It will be remembered that the Wilde and De Meritens machines had iron cores. These experiments of Mr. Siemens were not very successful, the motor frequently stopping suddenly, even when doing very little work; but they were of value for comparative purposes.

* Paper read before the Institution of Electrical Engineers.

† "On a Property of the Magneto-Electric Current to control and render Synchronous the Rotations of the Armature of a number of Electro-Magnetic Induction Machines." H. Wilde, *Phil. Mag.*, Jan., 1869, pp. 54-62.

Digitized by Google

Passing over the next few years, we find that the use of alternators had become of great importance on account of the growth and development of the transformer method of distribution, and that there was and is a certain amount of doubt and hesitation about working parallel. It is recognised that it has been and can be accomplished, but that the arrangement is not one to be thoroughly and completely depended upon in every case. And there is sufficient justification for this doubtfulness. The present opinion may be fairly stated as follows: Alternators may be successfully run in parallel if they have a good deal of self-induction, and to secure this it is better that they should have iron-cored armatures.

In his recent paper on "Alternate Current Machinery," before the Institute of Civil Engineers,* Mr. Kapp dealt at considerable length with this part of the subject, and his views, I need not say, may be accepted as quite correctly representing the current state of knowledge and opinion. Referring to alternators that have self-induction, negligible Mr. Kapp says: "Machines of this type can only be run in parallel if the strength of their field is adjusted with almost mathematical precision, and as this would require more skill and attention than is available with the ordinary staff of a central station, such machines are practically unfit for parallel working. To make them fit for this method of working, either the armature resistance or the self-induction must be increased. An increase of resistance in order to be effective, would have to be so considerable as to seriously prejudice the electrical efficiency of the machine, and this expedient may therefore be dismissed as impracticable. The other plan of increasing the self-induction is not open to the same objection. It has the effect of lowering the plant efficiency, but its influence upon the electrical efficiency is only indirect, and so small that it may be neglected. From the foregoing, it will be readily seen that the only and sufficient condition for successful parallel working is a sensible amount of self-induction in the armature circuit. If the armature itself does not possess the quality in a sufficient degree, a choking coil of suitable self-induction must be inserted into the circuit of each machine. The results here arrived at, by a mere theoretical investigation, are entirely borne out in practice. It is well known that alternators having no iron in their armatures cannot be run in parallel, except by the adoption of some such expedient as choking coils; also that parallel running is feasible with those alternators which have iron-cored armatures, and then with different degrees of security."

Now this is a very serious state of affairs, for it really means, if true, that the only machines suitable for central station supply are those that, on account of their high self-induction and resistance, are bad regulators that will not bear any considerable change of load without varying a good deal in E.M.F., and that are wasteful on open circuit.

For my part, I have seen enough of the use of iron in armatures to wish to do without it if I can, and I have repeatedly pointed out that, if iron is really necessary, the armature is the very worst place to put it. For the purpose of increasing the self-induction, it can be much better used outside of the machine, and put in some place where it is not subject to all the losses, restrictions, and disadvantages that necessarily accompany its employment in the core of an armature. If it is not in the armature, it can be entirely removed when not required for the purpose for which it is thought to be necessary—that is, when only one machine is in use. To put iron in an armature merely to increase self-induction, appears to show a want of common ingenuity and an absence of the sense of proportion.

But let us examine the evidence on this matter, in order to see what basis of fact there is for the present views.

In the first place, it will be found that the use of iron armatures is not in all cases to be relied on to give successful parallel working. In the discussion last year, Mr. Gordon, who has had very considerable experience, and who used iron largely in his machine, warned us in strong terms against working in parallel. He said:† "We know that experiments have been made by coupling a number of small alternate-current machines together, and at the South Foreland they were successful, but that was because they were working on arc lamps."

A little elucidation, perhaps, is necessary here—"Many of us have tried them, and they will, on trial, work together, no doubt, but they do not work together till they have run for three or four minutes. They will in that time jump, and that jumping will take months of life out of the 40,000 lamps. That alone is rather a serious difficulty in coupling machines together, and I think we may take it in practice—I am not speaking about the laboratory or experiments—that we do not couple machines."

The Zipernowski alternator will, however, work parallel, but apparently not very well. To get it to do so, the periodicity has had to be reduced to 42, as we now know.‡

Further, I have recently seen a communication from the highly-experienced makers of a well-known alternator in which iron is used, stating that, if it is desired to run parallel, the machines, engines, and arrangements must be in every way identical, the impression conveyed being that with this machine the greatest care is necessary to ensure a successful result.

Then, again, the large experience of the Westinghouse Company in the United States has shown that their iron-cored alternators will work in parallel under some conditions. We are told that, with these machines, "parallel coupling always succeeds when they are loaded to about half their maximum output or over, but that machines working under a less load cannot with certainty be so coupled."

But the other day Professor Forbes described§ successful parallel working with the iron-cored Lowrie-Parker alternators at West Brompton, even with very light loads.

* *Proc.* Inst.C.E., February, 1889.
† *Journal*, xvii., pp. 195-6, February, 1888.
‡ See under "Periodicity."
§ Board of Trade Enquiry. April, 1889.

Thus it will be seen that we have evidence ranging from complete failure to complete success with iron-cored machines.

It is proved, then, that the presence of iron is not alone sufficient to ensure success, for the use of iron is associated equally with failure and with success.

That the success attained is complete only as regards the fact of synchronism, is shown by the following extract from Prof. Forbes's remarks in the discussion on Mr. Kapp's paper, which I quote at some length, because Prof. Forbes has taken every opportunity of ascertaining by personal observation what is being done, and because he gives us what is alone of much service at the present stage—viz., the independent record of actual facts, and tells us clearly what the real difficulties are.

The passage is:* "The question of parallel working was one which had been very much discussed as to whether it was desirable or possible. . . . It was always possible, as Mr. Kapp said, with machines which had a very high self-induction—machines in which the armature had a great mass of iron in it. At the same time, the introduction of that self-induction into a machine reduced what Mr. Kapp called the plant-efficiency of the dynamo machine; and if they could work out, as he believed engineers would work out, some better means of making machines work in parallel, it would be very desirable.

Another reason why the heavy self-induction was injurious, was that it required such continued attention on the part of those in the station to see that the pressure was maintained constant. The electrical pressure varied so much, that the quantity of current being developed, as shown by the table of curves (Fig. 11) was seriously affected, and constant attention was required to keep such a machine regulated to the right pressure; whereas a machine which had no self-induction, or very little, gave off the same electric pressure, or nearly so, whatever the current might be, so long as the speed was maintained constant. As to the possibility of working conveniently in parallel with those machines, he might say that the experience of America had been completely against it. It was there found that it was possible to work in parallel, but that it enormously increased the amount of skilled attention required in a central station."

This is a very strong condemnation of the present system of obtaining synchronism, and at the end of his "Central Stations" paper† Prof. Forbes returns to the subject in these words: "I venture to think, however, that the plan now universally proposed for making machines work in parallel will not long be tolerated. This is to introduce into the machine a large amount of injurious self-induction, thus diminishing the plant efficiency, and rendering the equalising of pressure with various loads very difficult."

Turning now from alternators with to those without iron-cored armatures, we are brought face to face with the serious fact that, in spite of the many inconveniences connected with the use of very large machines, Mr. Ferranti is laying down the Deptford station to work with engines and alternators, each of several thousands of horse-power, and is depending upon the employment of spare engines and machines, of corresponding size, to prevent or to minimise the risk of wholesale extinction of the lights. It is understood that one of the principal reasons for doing this is that parallel working is not to be relied on.

The next question is, is it clear that, in order to be able to run them parallel, or as synchronising motors (for I need not say that the two qualities are inseparable, and are, in fact, identical), alternators should be bad regulators, should have large self-induction, or high resistance, or both? I think not. I have mentioned Mr. Gordon's machines, which certainly had the first of those qualities, but they would not run parallel. Other machines that I have referred to, and whose parallel working is not to be depended upon, are, at any rate, not remarkable for absence of self-induction.

Again, is the absence of iron from the armature cores alone sufficient to deprive a machine of self-induction, and to give it a straight characteristic? I think not; for I have tested machines that had no iron, but that had a good deal of resistance, very considerable self-induction, that had very crooked characteristics, and yet that would not run parallel under any circumstances whatever.

So we see that neither a bent characteristic, nor self-induction, nor resistance, nor the use of iron cores, nor even the simultaneous possession of the whole of these admirable features and qualities—that none of these things is the secret of successful parallel working.

Perhaps—and this is a dreadful reflection—it is the exact opposite of all these!

Now I am in the unenviable position of being out of accord with the theories, the practice, the principles, and the explanations of the very able men who have lately written, spoken, and worked on this subject. I have no doubt that all they have said is perfectly correct, so far as their difficulties are concerned—that they have experienced considerable trouble in working parallel, and have even in some cases met with actual failure. But this was partly because they have been unfortunate or unwise in the apparatus they have used, and partly because the principles that have been relied on to ensure success have not been in all respects suited to the case.

Although the conditions of the two problems are not in all points similar, I very respectfully submit that we are in danger of repeating the old mistake that was made regarding direct-current motors. We were taught that self-induction in the armatures was good, and that a special form and special proportions should be given to such motors; and I was very unorthodox when, in 1886,‡ I asserted that self-induction was not a virtue to be cultivated in motors any more than in dynamos, and, generally, that a good motor was a good dynamo—and *vice versâ*. However, it is some satisfaction to know that the

† *Journal* xviii., p. 195.
‡ *Phil. Mag.*, Jan., 1886, "The Dynamo as a Generator and as a Motor."

Digitized by Google

views I then expressed have received the sanction of general practice, although I am afraid that in the eyes of Profs. Ayrton and Perry those views remain as unorthodox as ever.

(*To be continued.*)

BOARD OF TRADE ENQUIRY.

Major Marindin, C.M.G., R.E., on behalf of the Board of Trade, resumed the enquiry at the Westminster Town Hall, for the purpose of hearing, on the part of a number of electric lighting corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

WEDNESDAY, APRIL 24.

Mr. J. B. Martin, one of the directors of the Westminster Electric Supply Corporation, Limited, called and examined by Mr. Wallace, said that the capital of the company was £100,000. All the portions of the city of Westminster had been abandoned during the enquiry with the exception of St. Margaret's, St. John the Evangelist, and St. George's, Hanover-square. The capital had been subscribed for the purpose of arranging for sites and the fitting up of some small plant near Victoria-mansions, which would cost about £8,000. The directors of the company were Lord Suffield, Sir John Heron Maxwell, Mr. Henry Kimber, M.P., Mr. H. Fisher, M.P., and himself. A great many of the gentlemen who had subscribed capital to the company were owners of property in the district of Westminster. They had engaged three sites for the supply of electricity, and were negotiating for two others for their battery stations. Two of them were wharves. They had entered into a contract for erecting plant with two large firms—Messrs. Crompton and Co. and Messrs Latimer Clarke, Muirhead, and Co. The parishes of St. Margaret's and St. John were to be lighted by Messrs. Crompton and Co., and the parish of St. George's, Hanover-square, by the other firm. Adjoining their property at Victoria-mansions a site had been purchased which was intended to be used as a battery site, and the plant there would be used as an auxiliary plant if required. The boilers had already been put down, and the other portions of the machinery would soon be delivered, which would supply about 5,000 lights.

Cross-examined by Mr. Pember, he said that they were registered as a company for the supply of electric light, which was to be their real business. They had no special patents to sell. He thought there were about 20 shareholders. It would not be difficult for him to give their names. He could supply them next morning. The value of their shares was £10 each. He held £50,000 himself. He might mention that that was not the maximum capital that they had power to raise. The present installation that they were fitting up would cost £8,000, and would supply 5,000 lights. The contracts they had entered into were for a much larger amount and a much larger district. They had arranged for 100,000 lights at so much per light. They had entered into contracts to supply certain areas at 35s. per light inclusive.

Mr. Latimer Clarke, examined by Mr. Wallace, said that his firm had had considerable experience in manufacturing electrical appliances, as well as in laying underground mains for telegraphic purposes. They had erected plant at St. James' station, which had commenced working, but not on a proper scale. There was a contract entered into with his firm for the supply of electric plant for 40,000 lights for St. George's, Hanover-square. That contract was based on so much per light. He thought that from the time of getting the order it would take six or seven months before the installation was completed. They would be able to supply 20,000 lights in about four months' time.

Cross-examined by Mr. Pember, he said that their estimates were about 30s. a light; but they had made a provisional contract, which was to be settled thereafter by arbitrators. There was nothing to prevent an arbitrator giving more than 35s. a light. They were to be paid in money. There was no provision for taking shares in the company.

By Mr. Moulton: Their system was the ordinary three-wire system, assisted by batteries at the outside stations.

Re-examined by Mr. Wallace, he said that his firm had so arranged matters that if there should be any exceptional work its cost was to be settled by arbitration.

In further reply to Mr. Pember, he added that they had told Mr. Martin that he could erect the whole of the lamps for 30s., and they were prepared to do their part of it at a price which would enable him to buy the sites and complete the work at that price.

Mr. K. Hedges, engineer to St. Stephen's Club, examined by Mr. Wallace, said that he had three clients anxious to take the light—the St. Stephen's Club and two other establishments belonging to the Aerated Bread Company. They would prefer to have it on the direct system with storage batteries. There would be a great demand for the electric light in the vicinity of Westminster on the direct system with storage batteries.

Cross-examined by Mr. Pember: It was a *sine qua non* at the present time that at St. Stephen's Club the light should be on that system. They had applied to the Metropolitan Company before that company was wired—some 10 months ago. The cause of the change that had come over their ideas in the matter of system was that the light at other clubs had failed. He had been told by the club officials that that was the reason. At a meeting of the committee he was asked whether, in his opinion, the system supplied by the Grosvenor Gallery Company would be sufficiently reliable, and he said he did not think so under existing conditions. He had mentioned in a little work of which he was the author that the alternating system was suitable for large areas. It was very much a matter of expense. There was no impossibility in point of principle or practice.

Mr. F. W. Anderson, electrician to Messrs. Latimer Clarke, Muirhead, and Co., examined by Mr. Wallace, deposed that his firm had erected the stations at St. James', which had worked satisfactorily. At present there were no batteries there. For St. George's, Hanover-square, it was proposed to have a battery supply.

Cross-examined by Mr. Graham, he said that the cells they proposed to use as a stand-by were the E.P.S. For an installation of 40,000 lights there would probably be four stations, each covering 10,000 lights.

Mr. Muirhead then opened his case on behalf of the St. James' and Pall Mall Electric Light Company, and said that he objected to the application of the London Electric Corporation, and also of the Metropolitan Company. His company was started in the St. James' district because there was great dissatisfaction in the parish at the unsatisfactory lighting on the part of the Grosvenor Gallery Company, and it was at the request of a great number of people in the district that a new company should be formed which should devote its attention to their requirements. The parish might be divided into two areas. First of all, there was the area to the south of Piccadilly, which contained all the clubs and a great many public buildings, which would require long hours of lighting. To the north of Piccadilly there was a poorer district, which was inhabited by working people, who required motive power, so that when the St. James's Company designed their system of supply they resolved to establish two stations—one in the south and one in the north. In the southern portion of their area the station was specially adapted for lighting purposes. In the northern the station was to be established for the purpose of supplying power, but in order that the northern station should be of use in the general system, the machinery was designed so that when the current was turned off in the northern portion of the parish it could be utilised in the southern to assist the machinery there at the time of the maximum supply. Soon after the incorporation of the company they applied for a license, and after prolonged negotiations with the parish the license was granted by the Board of Trade in December last. He might here say that the St. James's Company did not intend to go beyond the boundary of the parish, and they desired to meet the whole of the requirements of the parish. Having that object in view they had accepted all the amendments to their application proposed by the Vestry. The capital of the company was fixed at £100,000, but they had, of course, power to increase it. At the time the company was started a prospectus was sent out to the public setting forth the objects of the company, and while the subscription list was still open the Grosvenor Gallery Company—he had no doubt to protect their own interests and to try and prevent the successful floating of the St. James's Company, which was going to be a powerful competitor—issued a map to the public covered all over with red patches to show that the ground was practically occupied. That, however, did not affect the floating of the company. £28,000 was subscribed in the first instance, and the number of shareholders on the list was about 60. The company then purchased a site in Mason's-yard, the cost of which was £9,500. They spent on the construction of the building £8,500, and entered into a contract for the supply of machinery for 10,000 lights, at a cost of £18,500. That contract was divided into two sections. The first was for 5,500 lights for £11,000, and the second brought up the lights to 10,000 for £7,500. The first portion of the contract was now practically completed, and the company was about to lay down the first section of the mains. The system adopted by the company was the low tension and the machinery was subdivided in a manner similar to that of the Metropolitan Company at Whitehall. The system of distribution was known as the three wire, and the company proposed to establish a net work of mains through every street in the southern half of the parish. There would be a ring main running down St. James's-street, along Pall Mall, up Regent-street, and Piccadilly, connected by means of feeders with the station. He did not think it would be necessary for him to call any scientific witnesses as regarded the system of distribution and machinery, as they were well known, and beyond minor matters of regulation he did not think the machinery possessed any novelty.

Mr. Eustace Balfour, chairman of the board of directors of the St. James's Company, examined by Mr. Muirhead, said he was an architect by profession, and had paid personal attention to the erection of the machinery at Mason's-yard. His company proposed to confine its operations entirely to the parish of St. James's, and proposed to adapt themselves to the requirements of the public. They had acquired the freehold site at Mason's-yard, the capacity of which was for 35,000 lamps of 10 c.p. With accumulators he was told that they could supply any number up to 80,000 lights. They had commenced operations, and the light had given great satisfaction. They had met all the objections of the Vestry, and a license was granted to them in December last. Their system was the three wire, with a voltage of 110. Their district contained all the best clubs, and there were a great many rich people lived in it, and there were other public places, such as large banks and fine shops. They anticipated a large amount of lighting in the area. It was his opinion that for such a district special arrangements for lighting had to be made. They had no transformers, but eventually the company proposed to use storage batteries. Their boilers were specially constructed, the engines being of the Willans type, while the dynamos were supplied by Messrs. Latimer Clarke, Muirhead, and Co. He anticipated no nuisance from smoke or vibration. They would have no difficulty in finding what capital they required.

Cross-examined by Mr. Pember, he said that they could work without batteries, but it was intended to use them. They wished to have the batteries in hand in case of a breakdown. He was an enemy of competition in the sense that every company starting under the favourable auspices under which they started ought to have a chance in its

Digitized by Google

own district of satisfying the Board of Trade. Of their £100,000 nominal capital £28,000 had been subscribed. The directors were Mr. Hemmerde, Mr. Kirby, Colonel Francis, Mr. Royds, Mr. Latimer Clarke, and himself

Mr. James Hemmerde was next called and examined and cross-examined by counsel, principally with regard to the financial arrangements of the company, which concluded the cases of the applicants for provisional orders.

VESTRY OBJECTIONS.

The second stage of the enquiry were now entered upon—namely, the hearing of the objections raised by the various vestries to the granting of the provisional orders applied for—which lasted, practically, four days.

The first case was that of the Rotherhithe Vestry, represented by **Mr. Stokes**, who did not object to the preamble of the order, or to its general scope, but demanded protecting clauses in respect to the breaking up of the streets, the making of sewers, and the employment of overhead wires.

Mr. Nash, on behalf of the parish of Paddington, stated that the special objection there to the proposed orders was that the vestry were anxious to undertake the lighting of their own area themselves. Some months previously Prof. Forbes had reported on the subject, pointing out the cheapest and most effective way of lighting the district, and stated that there would be many advantages to the district if the vestry obtained the power itself.

Mr. H. L. Cripps, who represented the Strand Vestry, said that there were five companies applying for provisional orders to light their district, and the Strand Board, after considering which company, from its general position, was most likely to meet the requirements of the locality, decided on entering into the agreement with the Metropolitan Company already referred to. The points of that agreement were first, the definite appropriation of the different stations as the source of light in the district; second, the definite allocation for distributing mains over the entire area in positions agreeable to the local authority: third, the security that from such stations and mains an adequate supply of electricity would be produced for the district; fourth, an easy means of detecting the cause of any failure or deficiency in the supply of the district; fifth, an easy access to headquarters to lodge complaints and obtain a remedy; sixth, definite arrangements for preventing obstructions in the streets; seventh, the relief of the Board of Trade from the task of arbitrating between the local authority and the company with regard to works in the streets; eighth, freedom of the consumer from various onerous conditions with regard to obtaining a supply, and arbitrary powers contained in the provisional order; ninth, a system which pointed as far as possible to a harmonious working between the local authority and the company. The Strand Board thought that consent to the London Electric Supply Corporation's application ought to be withheld on the ground that jointed mains would involve a greater disturbance of the streets than the system of the Metropolitan Company.

Mr. R. W. Young, representing the Wandsworth District Board, said they wanted a clause to prevent the buying up of any company that might in future compete with the Metropolitan Company. They also recommended that the area of the generating stations should be circumscribed, and that some sliding scale should be incorporated in the order. They further suggested that, instead of 8d., the price inserted in the St. James's order—namely, 7d.—should be substituted.

Mr. Wilkins spoke on behalf of the St. James's Vestry, and said that their main consideration was whether they should adopt the principle of free trade or of districting. They had come to the conclusion, after mature consideration, that the principle of districting was as essential with regard to electric lighting as it ever had been in respect of gas, especially in view of the fact that there were now no less than 15 companies which had authority to lay mains in some of their streets. He thought that the whole of Mr. Ferranti's evidence pointed to the conclusion that the system proposed by the London Electric Supply Corporation was experimental. The dynamo to be used was larger than any yet constructed; the rigid concentric main was to be jointed at every twenty yards, which would be its weakest part; while the high tension of 10,000 volts had never been tried even on a small scale, and the corporation proposed to work with it over a distance of seven or eight miles. Consequently, after prolonged enquiry, the Vestry had adopted the St. James's Company, which used the continuous current at low tension, and the Metropolitan Company, which was already doing work in the parish at a moderately high tension on the alternating system. It was claimed for the Deptford scheme that there would be a net economy in the cost of production of 43 per cent., but at the same time he found that the London Electric Supply Corporation sought power to charge 8d. per unit, whereas the maximum price of the two companies assenting to the terms of the Vestry was only 7d.

Mr. Hitchins appeared for the parish of St. George's, Hanover-square, and examined **Mr. J. H. Smith**, the clerk to the Vestry, who stated that the London, the Metropolitan, the Westminster, and the Chelsea companies wrote asking for provisional orders to light the parish. Subject to certain amendments, the Vestry had no objection to the orders of the first three of these; but, in consequence of some correspondence that passed between them and the London Company, the Vestry had passed the following resolution: "That the Vestry do now approve of the application of the London Electric Supply Corporation, Limited, for a provisional order to enable the corporation to supply electricity in this parish, but upon the express condition that the corporation accept all the alterations and conditions which have been insisted upon by the committee acting on behalf of the Vestry, and that the order should be so amended as to clearly and distinctly embody the same."

Mr. Hewitt, who addressed the inspector on behalf of the Kensington Vestry, said that there were six companies competing for the district, two of which—the London and the Metropolitan—had withdrawn their applications. He desired to point out that it was most desirable that before generating stations were created in the district the sanction of the local authority should be obtained. The companies who proposed to light Kensington were not to be regarded in the light of benefactors, but merely as speculators engaged in a very lawful enterprise, and he ventured to think that the views of the local authority in matters of this kind should be fully considered.

Mr. H. L. Cripps said that the Vestry of Marylebone opposed the application of the London Company. The scheme which that company had adopted would entirely defeat, when the time came for its operations, those provisions of the Electric Lighting Act which ultimately enabled local authorities to acquire the undertaking. The Metropolitan Company had approached the local authority of Marylebone with suggestions for an arrangement which appeared to be satisfactory. If the Board of Trade sanctioned the order applied for by the London Company as regarded parts of the parish, it would operate in a way which seemed to him would be very unreasonable, inequitable, and inconvenient. If it were granted, the effect would be that the Metropolitan Company would be placed in competition in the best part of the district with the London Company.

The parishes of St. Margaret's and St. John's, Westminster, were also represented by **Mr. H. L. Cripps**, who stated that as regarded the London Company's order his board had had an opportunity of inspecting the works at Deptford, and had obtained all possible information, and were of opinion that it was desirable that electric light works should, as far as possible, be kept out of large centres of trade and business; and that public authorities should be placed upon more favourable terms in respect to public lighting than they now were.

Mr. Coates, representing St. Pancras Vestry, said that they had got powers under a provisional order granted in 1883 to light the whole of the parish of St. Pancras, and being entirely independent they considered that no company should be allowed to go into their district and compete with them because they were more likely to make the lighting pay than any company would be, because they would have no dividend to pay, and could raise money for the purpose at 3½ per cent.

Mr. Moulton stated that the telephone companies said that they required a clause inserted in all the orders ensuring electrical quietude in the metropolis.

Mr. Russell Griffiths, on behalf of the City authorities, opposed the granting of a provisional order to either the Metropolitan or the London Company, which concluded the cases of the local authorities.

COMPANIES' MEETINGS.

MAXIM-WESTON ELECTRIC COMPANY.

The statutory ordinary general meeting of the Maxim-Weston Electric Company, Limited, was held on Thursday in last week at Winchester House, Old Broad-street, E.C., under the presidency of Mr. John Marks.

The **Chairman** said there was no resolution to be submitted to the shareholders; but, as they had had to be called together, he would take the opportunity of making a few remarks. In the first place, they had, unfortunately, lost the services of two Directors Mr. Harvest had been taken away by death, and Mr. Hildyard had resigned because his business required the whole of his time and attention, and he therefore felt he could not do justice to the work of this Company. Of the 312,000 shares at their disposal on the reconstruction of the Company 262,000 were applied for, so that only 50,000 remained. These the liquidators had requested the Directors to offer to the shareholders, if they were disposed to take them. At the time the applications were made for the new shares a large number of shareholders applied for more than they were legally entitled to, and the Directors could not, therefore, allot them. If those shareholders were now desirous of tendering for them, or any portion of them, on the understanding that the tender would be for the extra 1s. per share not paid up, the Directors would be happy to consider their applications. If they did not apply, the Directors could place everyone of those shares within 24 hours. The applications must be made within seven days of the issue of the circular, which was being prepared. The dissentients in the old company numbered from 24,000 to 25,000 shares, but he was happy to say they had been able to arrange a settlement with those dissentients on terms fair to them and to the new Company, and there would be no litigation whatever in regard to them. The Directors had secured the services of Mr. Hamilton as general manager, and he believed at the end of the financial year they would be able to come before the shareholders and give a good account of their stewardship. They had concluded some contracts, and others were under negotiation. One they had concluded was for 1,000 lights, and it was likely to lead to greater results. The Directors considered the Company in a very satisfactory position. The end of the financial year, he added in reply to a shareholder, would be at the end of March next.

The proceedings then concluded.

WOODHOUSE AND RAWSON, LIMITED.

An extraordinary general meeting of the shareholders of this Company was held last Friday at the City Terminus Hotel.

Lieutenant-General Sir John Stokes, who presided, stated that the advance in electrical work which he mentioned at their meeting last December had continued, and during the past few months there

Digitized by Google

had been a great extension of electrical enterprise in all directions. Their business was steadily progressing, and their installation work was fully appreciated. When they considered the large amount of central station work that was being done in London with 21 central stations, and in other parts of England and the Continent, the outlook was very encouraging. Their general business had steadily increased outside of electrical work, and they had taken out and acquired several valuable patents, chiefly electrical, during the past year. Abroad, there had been a gratifying increase in their business. With regard to the Elmore patents, in which they were interested, the Elmore Patent Copper Depositing Company, which he mentioned at the last meeting, had been successfully brought out, and the statements made as to the value of the process had since been more than proved. The proposed amalgamation with, and the sale of their undertaking to the new company was on the lines approved at the last meeting—that they received now their dividends up to June 30 last, together with a bonus of 10 per cent. upon the amounts paid up on their shares from the new company. In addition certain assets were to be distributed among them. By the sale to the new company the founders' shares would be done away with, thus enabling the payment of larger dividends. The distribution now proposed would make 12 per cent. for the year. He concluded by moving the adoption of the accounts and the declaration of the dividend mentioned.

Mr. Lambert seconded the motion, which was carried; and a resolution was afterwards passed approving the agreement for the sale of the undertaking of the Company to a new company for shares and debentures of the latter.

NEW COMPANIES REGISTERED.

Bahia-Blanca and North-Western Railway Company, Limited.—Registered by Ashurst, Morris, Crisp, and Co., 6, Old Jewry, E.C., with a capital of £2,000,000 in 13,500 preferred and 6,500 ordinary shares of £100 each. Object: to acquire, construct, complete, and equip, maintain, prolong and work railways and their appurtenances, tramways, lines of telegraph, telephones, or other means of communications, or appliances of a similar nature in the Argentine Republic, and for such purposes to enter into and carry into effect any contracts, and apply for, accept and carry into effect such concessions or authorities as may be deemed necessary or desirable; to acquire mining powers, rights or easements over any railway, tramway, or line of electric wire, or other similar means of communication. T. Winter, 9, Bowness-road, Catford	1
E. Botwright, 23, Sutton-place, Hackney	1

The number of Directors shall not be less than three nor more than seven, the first to be appointed by the subscribers to the memorandum of association. Qualification: £500. Remuneration: £3,500 per annum, divisible as they determine.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for the week ended May 17 amounted to £4,932.

Western and Brazilian Submarine Telegraph Company.—The traffic receipts of this Company for the week were £3,544.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended May 15 were £3,141, against £2,852.

United Telephone Company, Limited.—The Directors recommend a dividend for the half-year ending April 30 at the rate of 12s. 6d. per fully paid share, less income-tax, making, with the interim dividend, a total distribution for the 12 months of 17½ per cent.

Consolidated Telephone Construction and Maintenance Company, Limited.—This Company, in their report for the year ending March 31, shows a profit balance of £13,286. The Directors propose a further dividend of 7 per cent. for the half-year, making, with the interim dividend, 6 per cent. for the year, writing off £520 for depreciation of plant, machinery, and furniture, and £2,000 from goodwill, patent rights, etc., leaving £1,558 to be carried forward.

PROVISIONAL PATENTS, 1889.

MAY 13.

7919. **Improvements in apparatus for making certain articles of pottery-ware, such as electric lamp roses, switches, fuse blocks, and the like.** Richard Thomas Grocott, Longport, Staffordshire.

7947. **Improved method of crossing the ends of drum armatures of dynamos.** John Farquharson, Pomona House, King's-road, Fulham, London.

7976. **Improvements in arc lamps.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

7948. **Improvements in bleaching paper pulp by electrolysis.** Emile Marie Hippolyte Andreoli, 62, Loughborough-park, Brixton. (Complete specification.)

MAY 14.

7992. **Improvement in combined telephony and telegraphy.** Herbert John Allison, 52, Chancery-lane, London. (James Hart Robertson, United States.) (Complete specification.)

7993. **Improvement in exchange or central office systems as applied to telegraphs, especially autographic telegraphs.** Herbert John Allison, 52, Chancery-lane, London. (James Hart Robertson, United States.) (Complete specification.)

8030. **Improved automatic switch for charging electric accumulators and like purposes.** Max Emil Unger, 89, Chancery-lane, London.

8046. **Improvements in electrical fire-alarms.** Henry Edward Newton, 6, Bream's-buildings, Chancery-lane. (William Birchall, Victoria.) (Complete specification.)

8053. **Improvements in electrical signalling apparatus.** Oliver Imray, 28, Southampton-buildings, Chancery-lane, London. (Alfred Walker Jones, Benjamin Franklin Jones, and Edward Lowe Martin, United States.) (Complete specification.)

MAY 15.

8070. **Improvements in telephonic switching apparatus.** Alfred Rosling Bennett, 62, St. Vincent-street, Glasgow.

8113. **Improvements in or applicable to electrical cells or batteries.** Henry Edward Joël and John Stephen Cassal, 226, High Holborn, London.

8115. **Improvements in the thermo-magnetic generation of electric currents and in apparatus therefor.** William Henry Snell, 70, Chancery-lane, London.

MAY 16.

8143. **Improvements in instruments for measuring electric currents.** Philip Jolin, 35, Narrow Wine-street, Bristol.

8157. **Improvements in switches for electric signalling apparatus.** Leopold Sellner, 45, Southampton-buildings, London.

8195. **Improved arrangement for paying out drums for laying submarine cables.** Richard Harnett, 65 and 66, Chancery-lane, London.

MAY 17.

8213. **Improvements relating to the method and means employed for coupling alternating current dynamo machines in synchronal relation, and to the control of motive power engines used for driving the same.** Wm. Lowrie and Charles James Hall, 433, Strand, London.

MAY 18.

8290. **Improvements in electric switch boxes, ceiling roses, and other articles, where it is desirable to have two glass, earthenware, or porcelain parts, such as a box and lid, screwed or attached together so as to permit of easy detachment.** George Crosland Taylor and James Taylor, 6, Lord-street, Liverpool.

8318. **Improvements relating to dynamo-meters.** August Ackermann, 4, South-street, Finsbury, London. (Date applied for under Patents Act, 1883, Sec. 103, 20th October, 1888, being date of application in France.)

SPECIFICATIONS PUBLISHED

1888.

5811. **Generating, &c., electric power.** Crompton and Swinburne. 8d.

7408. **Electrical fuses for firing blast holes, &c.** Boult (Manet and another.) 6d.

9672. **Dynamo-electric machines, &c.** Lowrey and others. 11d.

1889.

2071. **Electric systems.** Ferdinand. 8d.

2952. **Electric relay apparatus.** Lake (Dressler.) 11d.

4722. **Electric conductors.** Lake (Griggs.) 8d.

4800. **Electric conductors.** Lake (Brooks.) 6d.

5095. **Secondary batteries.** Haslam. 6d.

NOTES.

Buenos Ayres.—A central station is now in progress at Buenos Ayres for a total of 30,000 Edison lamps.

Peru.—A long-distance telephone line has just been opened by an English company from Callao to Lima, in Peru.

That's the Way.—A law has just been passed in the State of Michigan enabling gas companies to go into electric lighting.

Prague.—A central electric light station is to be erected for the Municipality of Prague by the firm of Waldek and Wagner, of that town.

Chelmsford.—The contract of the Town Council of Chelmsford with Messrs. Crompton and Co. for the public lighting of Chelmsford was sealed on Wednesday.

Smoking Concert.—The next smoking concert of the O.S.A., the final one of the season, is to be held on Saturday, June 15, at the Manchester Hotel, Aldersgate-street, at 7.30 p.m.

C & C Motors.—It is interesting to note that small electric motor work is not standing still. We understand that Messrs. Shippey Bros. have sold over 1,100 C & C motors in Great Britain and France during the last six months for driving ventilating fans, sewing machines, and other similar purposes.

Brighton.—We learn that Mr. Albert Gay, late of Taunton, who was recently appointed manager at the Eastbourne electric light station, has now been appointed manager to the Brighton and Hove Electric Light Co. A new central station will be erected shortly at Brighton, under the new manager's superintendence.

Liverpool Tramways.—One of the accumulator cars of the Electric Traction Company now at Barking-road will be sent shortly to Liverpool to test upon the tramways in that town. The gradients in Liverpool are rather steep, but there is probably little doubt that electric storage cars will eventually be adopted on these tramways.

Bank Lighting.—The Bank of Africa have determined to introduce the electric light, and have placed the order with Messrs. Drake and Gorham, who have had probably the largest experience of any contractors in this particular class of work. A 4 h.p. Otto gas-engine will be employed to drive a 5-unit Elwell-Parker dynamo for charging 33 of the firm's latest cells.

Havanna.—A central station has just been completed at Havanna by a Spanish-American company. The Westinghouse alternating system is employed for the incandescent lamps, with the Waterhouse system of arc lamps. The 1,500 incandescent lamps already installed are much appreciated. Westinghouse engines are used, of 130 h.p. for the incandescent lamps, and 75 h.p. for the arc lamps.

China.—The Chinese papers mention that electric lighting is becoming general in all their large cities, and is gaining ground in the smaller places. Pekin, Hong Kong, Shanghai, Canton, and other large cities have now a considerable number of lights. At Victoria, the capital of Hong Kong, we learn that a public company has been formed, and the machinery for a central station has just been ordered from Messrs. Johnson and Phillips.

Where was the Paper?—Where was the paper? and who was it by? are the questions that were asked at the Society of Arts on Tuesday. The paper on the Westinghouse System, said the notice, was to be by Mr. James S. Humbird: the *Journal* said it was by Mr. O. B. Shallenberger: the secretary announced it would be read by Mr. Belfield. But the paper didn't turn up, and nobody knows who it was by and what it was about to this day, as far as we can learn.

Holborn District.—The Works Committee of the Holborn District Board reported that they had received an application from the Gwynne-Pilsen Lighting Company for consent to supply electricty within the Holborn district. They recommended that the consideration of the subject be deferred until the report of Major Marindin has been made in reference to the electric lighting schemes referred to him to enquire into. The matter was referred back to the committee.

Old Students' Association.—The next meeting of the Old Students' Association is to be held at the Central Institution, South Kensington, when a paper will be read on "The Economical Use of a Primary Battery, based upon the Recovery of Zinc," by P. G. Nicholson, F.C.S., member. The paper will deal with the history of the Lalande battery; E.M.F., etc.; products of chemical reactions in cell; methods of recovering zinc as chemical compound; methods of recovering zinc as metal; and probable economy of the process.

Paris Congress.—The International Congress of Electricians, to be held at Paris, in August, during the time of the Exhibition, will not undertake, as has been thought possible, any redetermination of the standard ohm. This congress is not definitely under Government authority, and any action of this kind could only be taken authoritatively by the continuation of the previous congress of 1881, under the French Government. This will probably be held in 1891, when the question of the value of the real ohm, it is anticipated, may be definitely settled.

Train Lighting.—The Midland Railway Company began on Wednesday night to use the electric light on the system mentioned last week, the light being used for the first time on the London and Manchester and Liverpool express. The system of separate accumulators and couplings allowed the train to be broken up as desired, and the dynamo was found to be easily regulated. During the stoppage of the train to change engines the light was kept perfectly steady by the accumulators. The lamps are of 8 c.p., two in some compartments, and four in others. The appearance of the carriages was very brilliant, and the trial was a perfect success.

Temporary Lighting.—On Wednesday evening last Messrs. Woodhouse and Rawson, Limited, carried out a very successful example of temporary lighting at the Drapers' Hall. The permanent lighting of this hall is also under their maintenance, but on the above-mentioned occasion the light was required for the courtyard. This was covered over with a canvas roof, and in the centre, where the drapery was suspended from a centre ring, a large paper Japanese umbrella was hung, from the points of which were dropped 40 10-c.p. lamps, making a very effective electrolier. Below this was a large terra-cotta basin filled with beautiful exotics. The surrounding corridors were lit by suspended lamps in ornamental shades. The current was supplied from 53 E.P.S. cells of the 23 L type.

Acid Proof Material.—We are asked for further information with reference to the new acid proof material for lining accumulator cells referred to on p. 416 last week, in the paper on secondary batteries by Mr. Appleton. A correspondent remarks that if such a material is available at not too great cost it will be a great boon, adding that he has a large battery of Planté cells which has become quite useless from leakage, and has tried almost every means to prevent it. We believe we are not telling secrets when we state that this valuable material, which can be bent about and moulded like indiarubber and soldered almost like lead, is a special material manufactured for this purpose, which Messrs. Appleton, Burbey, and Williamson will shortly introduce under a license from the patentee.

Proposed Telephone Convention.—In a circular published last week by the *Electrician*, issued by Dr. Julius Maier, calling attention to a telephone convention to be held in London on July 11, 12, 13, it is stated that the proposed convention has been organised by the representatives of the telephone companies and the Post Office. This statement of the status of the convention should be contradicted at once. We understand that the Post Office have taken no part whatever in the convention, and it is in no way under their authority or initiative. We believe the mistake has arisen from the fact that Mr. W. H. Preece has consented to be present, but this is in a private and electrical capacity, and not as a representative of the Post Office, who consistently refuse to lend their authority to meetings or conventions.

Telegraph Signalling Station.—The movement to have a telegraph signalling station on Tory Island, off the north-west of Ireland, says the *Financial News*, is again being pressed. It is stated that a traffic of £38,000,000 annually passes, the vessels engaged employing a quarter of a million of men. The lighthouse, visible 30 miles off, is the first thing sighted by homeward-bound vessels taking the northern route; but the absence of a telegraph seriously reduces the value of the outpost. The "Bolivia," with broken main shaft, once lay off the island two days before a stray tug carried news of her need of assistance to Buncrana, the nearest telegraph office. Some merchants interested propose to give a guarantee of 2½ per cent. on the capital involved for three years, to encourage the Government to make the necessary outlay, about £4,000.

Electric Launches.—One of Immisch's electric launches was to be seen at Messum's, at Richmond-on-Thames, last week, and a very neat and handsome boat she is. This one is about 25ft. long, though others are made up to 75ft. A comfortably fitted cabin, furnished with velvet seats and paddings, takes about half the space at the back, and in front, in the open space, are seats on both sides of the boat. Under these the storage cells are placed, and the electric circuits lead to a strong and neatly finished switch with three levers for different speeds. The same arrangement is fitted inside the cabin, so that the vessel can be controlled from either inside or out. Power is obtained from two propellers fitted to Immisch motors, and the motion on the river is very quiet and unobtrusive—a great improvement to both those in the launch itself and those in other boats.

The Woodward Storage Battery. — Messrs. Shippey Bros., Limited, have been appointed sole agents for the Woodward Electrical Company of Detroit, for the sale of the Woodward storage battery. From accounts in the American Press the battery is coming into considerable use in the States. The company have recently extended their works, and have now facilities for turning out some 1,000 cells a week. The battery is really formed of a spongy lead plate, and it is claimed by the makers as being the only practical one of this kind, dispensing with the grid. In manufacture, molten lead is poured into a vessel containing salts, round which the lead solidifies. The salts are afterwards dissolved out, the solid block being sawed into plates. The Woodward battery, which is also known as the Detroit battery, is already in considerable use for traction work, and is said to stand a very heavy rate of discharge. A considerable number of these batteries are on their way to England, when users in this country will have an opportunity of testing their capabilities.

Edison and Swan Company.—The Edison and Swan Company inform us that the directors have resolved for the present to give up installation work, and confine themselves practically to the manufacture of lamps, fittings, and instruments. These branches of their business will be considerably extended, and the company hope to obtain as much credit for their electrical fittings and instruments as they have obtained for the Edison-Swan incandescent lamps. The company intend to manufacture fittings of the best workmanship even if obliged to charge a somewhat higher price than is charged for inferior articles. They have made arrangements with Messrs. Mather and Platt, of the Salford Iron Works, Manchester, to undertake the installation work which they have heretofore carried on. Messrs. Mather and Platt have been sole manufacturers for the company of the well-known Edison-Hopkinson dynamo, and will continue to make the same under license from the company, as well as their own Manchester dynamos. Mr. Blackburn, who has been the Edison-Swan Company's resident engineer for some years past, has, as we have already mentioned, now joined the staff of Messrs. Mather and Platt.

Telephone Amalgamation.—The amalgamation of the three large telephone companies, the United, the National, and the Lancashire and Cheshire will take place, it is stated, by the purchase of two of them by the third, the purchasing company giving its shares in payment. As the licenses held by the companies extend to the whole of the United Kingdom, any one is sufficient to cover the business of all three companies when amalgamated. The National Company is the one selected to absorb the others, as its shares stand nearest to par in market value; but, owing to legal considerations, the National Company's shares can only be taken at their par value, it is therefore necessary to nominally reduce the figures originally proposed as the basis of the amalgamation, which were the then market price of the shares, by one-sixth all round. The figures will then be as follows: The National Company's ordinary shares representing the purchase price are taken at par, £5; the United Telephone Company £12. 10s. for each share; and the United Telephone Company £1. 6s. 3d. for each share of the Lancashire and Cheshire Company. The new arrangement will take effect as from May 1 this year.

The Weymersch Primary Battery.—Some time ago we published a very favourable report of the Weymersch primary battery, and have since mentioned that the India Rubber Company, of Silvertown, were making

Digitized by Google

arrangements to manufacture it. They have now issued a price-list which contains an illustrated description of this battery, which, as most of our readers know, is one which is held to be suitable for supplying a fairly large current to small electric light installations for train lighting, or for driving motors where a dynamo is not available. The battery, as arranged, is made with six cells in an ebonite trough, with stoneware taps and flexible tubes, to allow two barrels of the charging solution to be placed near, and so dispense with the usual trouble of refilling, the battery being charged or emptied by merely turning the taps. The E.M.F. of the battery is 13 volts; the internal resistance of the six cells is 0·30 ohm, and the current available is 15 amperes. A thoroughly well-arranged primary battery, even if burning zinc, is very desirable under certain conditions, and the Silvertown Weymersch battery will, no doubt, prove exceedingly convenient.

Annual Dinner.—The annual dinner of Messrs. Crompton and Co., Limited, is fixed to take place to-day (Friday, May 31). Amongst others who have accepted invitations are the following: Messrs. Absalom, A. Court, Alabaster, J. S. Brown, C. H. W. Biggs, S. Bright, J. W. Board, A. Burton, A. G. Brown, Brunton, T. O. Callender, F. Chancellor, B. Drake, R. S. Erskine, Evans, Fyers, Fraser, Basil Gee, G. A. Grindle, Granville Ryder, Gorham, G. Gilkes, T. E. Gatehouse, C. O. Grimshaw, T. Godlee, Gibson, R. B. Hayward, R. F. Hayward, Hoyle, Hamilton, H. S. Holt, Hall, T. W. Hollick, Wilson Hartnell, Izard, A. B. W. Kennedy, G. Kapp, McFarlane Gray, F. Medcalf, Morgan, J. A. Fleming, Newington, Captain Holden, Preece, Paxman, A. H. Pott, Price, Pischon, F. R. Reeves, Rogers, Rawson, M. Robinson, Reckenzaun, J. H. Scrutton, P. E. Scrutton, J. Slater, Selby, H. Stevenson, Statter, Scott-Moncrieff, Sully, S. Stokes, C. E. Spagnoletti, J. Swinburne, Seckham, Shoolbred, I. A. Timmis, Thornton Unwin, S. Waters, F. Whitmore, T. Whiffen, Weston, H. U. Wollaston, M. J. M. Williams, N. G. Wells, Wakeford, and Woodruff. It is expected that altogether rather more than 100 guests will be present.

The Edison Combination in America.—The Edison combination, alluded to some time ago, has now been incorporated in America with a capital of 12,000,000 dollars. The name of the new company is the Edison General Electric Light Company, and it will acquire the stocks of the Edison Electric Light Company, and the three Edison manufacturing companies—viz., the Edison Machine Works, the Edison Lamp Company, and Bergmann and Co. Arrangements are also being made to acquire stock in the Sprague Electric Railway and Motor Company, should it be found desirable to do so. The new company pay partly in cash and partly in stock, the purchase price of the three manufacturing companies being calculated equal to a capital sum in which their net earnings, as shown in their books for the year ending November 1, 1888, will show a profit of 15 per cent. In order to add greater security to the project, dividends will only be paid on the old stock at first, dividends on the remainder being postponed until the directors are of opinion that at least 8 per cent. has been earned. Mr. J. B. Williams is president of the new corporation, and Mr. J. H. Herrick, who will take an active part in the management, is vice-president. No change will occur in the *personnel* of the companies, which will be carried on as departments of the consolidated concern.

Experiment with Mordey Alternators.—The value of Mr. Mordey's work in electrical engineering is greatly enhanced by the clear and able manner with which he gives his results and his conclusions to his colleagues in the electrical world. It was not sufficient for him to state what could be done in paper last week at the Institution, but the members were invited to see the actual experiments on a practical scale carried out at the Brush Company's works on Friday morning last. The visitors were met by Mr. Garcke, Mr. Mordey, Mr. Raworth, and other members of this company, and shown the Mordey Victoria alternators working as generators in parallel, and also as motors. The load put on the alternator whilst the visitors were present was about 25 to 30 h.p.; but we are informed that since then the alternator has been equally successfully run as a motor working at 50 h.p. As Mr. Mordey has fully explained his views in his paper, we shall refer our readers to the paper itself for a description of the experiment. With regard to the heavier load above mentioned, Mr. Garcke says: "We were not able to put so large a load on the machines on Friday, but took the first opportunity of doing so, and a continuous run has fully demonstrated the truth of the views set forth in Mr. Mordey's paper that a properly-controlled alternator would work equally well and equally efficiently, whether its output is mechanical or electrical—that is to say, whether it is a motor or a generator."

Board of Trade and Parliament.—In the House of Commons, on Thursday last week, Sir G. Campbell asked the President of the Board of Trade whether Mr. Calcraft's letter of May 18 regarding electric lighting in the metropolis correctly expressed the present intention of the Board of Trade to adopt Major Marindin's proposals to set aside the provisions of the Act of Parliament of 1888 requiring the previous consent of the local authority in many cases; whether the Board of Trade had approved the proposal of Major Marindin that the mere objection by a local authority should not be considered sufficient to exclude any company unless the local authority was itself ready at once to undertake the supply of electricity, and gave evidence of its intention to do so, and whether that alone would be a sufficient ground for a special report in each case stating grounds for dispensing with the consent of the local authority as required by the Act; and whether, in case he finally determined to give concessions to companies without the consent of the local authorities, he would take care that his special report on each case was laid before Parliament in sufficient time. Sir M. Hicks-Beach replied that Mr. Calcraft's letter correctly expressed the present intention of the Board of Trade. Major Marindin's report, however, did not go so far as is suggested in the second paragraph of the question. If in any case the consent of a local authority is dispensed with, the special report of the Board of Trade will be laid at the earliest possible moment before Parliament. It would not be consistent with the provisions of the Act of 1888 to insert in any provisional order any clause injuring or restricting the subsequent granting of a license or provisional order to the local authority or any other person within the same area.

The Conversazione of Electrical Engineers.—The annual conversazione of the Institution of Electrical Engineers was held last Friday by invitation of the president, Sir William Thomson, and Lady Thomson, at the rooms of the Royal Institution of Painters in Water-

Digitized by Google

Colours, Piccadilly, and proved to be one of the most successful of these social gatherings ever held amongst the profession. The guests numbered 735. Nearly all the leading members of the Institution were present, and among visitors who were non-members were the following: Sir Arthur Blackwood, K.C.B., Sir James Crichton Browne, L.L.D., F.R.S.S. (L. & E.), Sir Henry Doulton, Sir Thomas Sanderson, Sir John Coode, K.C.M.G., Sir Juland Danvers, K.C.S.I., General Eccles, Admiral Fitzroy, C.B., Captain Creak, R.N., Captain E. M. Shaw, C.B., Colonel Sir James Grant, C.B., F.R.S., Captain Fisher, R.N., Major Marindin, R.E., Captain Boyle, Dr. G. C. Wallich, Prof. Frankland, F.R.S., Dr. John Rae, D.C.L., F.R.S., Dr. Gordon Hardie, Prof. Hering, Prof. H. Robinson, Dr. William Pole, F.R.S.S. (L. & E.), Dr. J. H. Gilbert, F.R.S., Dr. W. N. Perkin, F.R.S., Prof. W. N. Hudson, M.A., Prof. H. E. Armstrong, F.R.S., Dr. W. J. Russell, F.R.S., Prof. James Grove, F.C.C., Dr. Hugo Müller, F.R.S., Prof. Hulme, F.R.S., Prof. Meldola, F.R.S., Prof. G. J. Romanes, L.L.D., F.R.S., Prof. Govier Seeley, F.R.S., Prof. John Milne, F.R.S., Prof. Hales, M.A., Prof. G. T. Bonny, F.R.S., Prof. W. Ramsay, F.R S., Dr. Bell, F.R.S., Mr. J. G. Symons, F.R.S., Sir Lowthian Bell, Bart., F.R.S., Lord Sudely, F.R.S., the Earl of Crawford and Balcarres, F.R.S., Mr. Charles Cochrane, M.I.M.E., Mr. William Anderson, M.I.C.E., Prof. W. N. Shaw, M.A., Mr. Ludwig Mond, F.C.S., Mr. R. Brudenell Carter, F.R.C.S., Mr. George Berkeley, M.I.C.E., Mr. T. H. Blakesley, M.A., Mr. Jacob Brett, Mr. H. J. Chaney, Mr. Charles Hawkesley, Prof. Huntingdon.

Severe Test to Underground Mains.—A curious accident happened last Sunday at West Brompton which might have caused considerable damage but for the excellent insulation of the House-to-House Company's mains. At about 3 a.m. the West Middlesex Water Works Company's main pipe, 5in. in diameter, in which the water is at a pressure of 125lbs., burst in Barkstone-gardens. The quantity of water that escaped was so great that it inundated the road and caused the ground to sink considerably. The water-pipe was laid 3ft. 6in. below the road level, and the House-to-House Company's electric light mains were about 2ft. 6in. above this pipe. One of their road boxes was exactly over the spot where the pipe burst, and as a large quantity of soil was washed away this box was lowered some 18in. The pipes followed the box, yielding only at the cork joints, and without a single breakage of the wires. The pipes filled with water, which travelled along and trickled into the basements of one of the houses the company are lighting; but, nevertheless, the cable continued to run the lights satisfactorily. This may be considered as a very severe test for any underground system of electric lighting to withstand. Indeed, the gas fared worse than electric light, for a lamp-post 10 yards distant fell down with a crash under the exceptional sinking of the road. Twelve cartloads of gravel had to be put on in order to bring the road to its proper level. The electric mains were raised to their proper position, without the slightest interruption to the working, within 24 hours of hearing of the accident that had occurred. The copper mains of the House-to-House Company's system are very highly insulated, and this fact stood them in good stead. Such an accident is exceptional, but had it occurred in a system employing bare copper wires underground, the result could hardly have failed to be a complete breakdown.

The Barking-road Tramway. — Major-General Hutchinson and Captain Cardew last Saturday visited the Barking-road line of the North Metropolitan Tramways to inspect the new accumulator cars of the Electric Traction Company, and to test their working. After an exhaustive trial these gentlemen expressed themselves thoroughly satisfied with the running and the manner in which the arrangements have been carried out, and a Board of Trade license will no doubt be shortly granted. There are now six new cars ready at the tramcar station for this line, besides the trial car, which we fully described some time ago (September 28, 1888). The six cars are every bit as well furnished as this one, and are furnished with sundry slight improvements upon the first car, one, for instance, being that they are fitted with garden seats on the roof instead of the longitudinal ones which were shown in our illustration. The car-house at the depot is simply filled with storage batteries on long benches. There are six trays of four double cells for both sides of each car, making 96 cells per car. There are six cars, and double sets of accumulators to each car, making over a thousand cells in all. The spray from charging all these cells together will, we fear, cause some trouble to the fittings of the cars unless careful attention is given to the ventilation. Two semi-portable engines capable of indicating up to 120 h.p. each are now erected; and one Immisch dynamo, giving about 115 amperes and 230 volts, is used for charging. A similar dynamo will probably be added shortly, as the whole of the plant will be in duplicate for safety in running. The cells are charged in series in six separate circuits, and resistances are arranged to secure the equal charging of all circuits. The trays of cells make their own connections by springs on being taken out of the cases and slipt upon the benches, fitted with metal pieces, which are arranged on each side of the car track in the depot. The whole of the cars have been carefully tested, and are ready to begin proper running at once. It is expected that one or two of the cars will be run among the horse cars at first, till the drivers get accustomed to the new method of working.

Finsbury Students' Conversazione.—Last Thursday and Friday a conversazione was held at the Finsbury Technical College by the Finsbury students (by the way, not the Old Students' Association, as inadvertently mentioned last week). It was a distinct and undoubted success. The rooms of the college were crowded from basement to chemical laboratory with visitors, students, and their friends, and we are sorry that none of the committee of the college thought well to turn up, as the sight of such activity would have gladdened their eyes. During the evening Prof. Thompson gave a spirited and interesting discourse upon the development of the arc lamp, historically and scientifically, entitled "Arcs and Sparks," which was much appreciated. Music went on in other rooms, and the whole of the college was decorated and fitted with interesting exhibits. The Acme Works were forward with a large exhibit of fittings, switches, fuses, glass, and cut-outs of all descriptions. Messrs. Nalder Bros. had a very fine exhibit of beautitully-finished electrical testing instruments, galvanometers, and voltmeters. The Edison-Swan Company sent some of their lamps and Fleming and Gimingham's ingenious testing instruments. They also showed one of their focus lamps for lanterns, in which the carbon is curled into a very small space for intense light. Messrs. Binswanger and Woodhouse and Rawson sent fittings. Mr. Pitkin

Digitized by Google

showed his lamp and Pitkin and Niblett's firedamp detector, Mr. Niblett attending in person. The Brush Company and Paterson and Cooper showed specimens of their apparatus and parts of dynamos. The Bernstein Company lighted the laboratory and showed their series incandescent system. Drake and Gorham had a most interesting set of exhibits of accumulators, fittings, ammeters, etc., and the transformer safety device we mentioned last week. Curious and interesting specimens of metal welding were shown by the Thomson Electric Welding Company. Messrs. Immisch, Statter and Co., and Appleton and Burbey also sent their specialities, and the Planet Engineering Company had an Alpha arc lamp. Besides these, some interesting historical instruments were on view—Hughes' balance and the original apparatus used by Foucault to measure the velocity of light, lent by Mr. Conrad Cooke. It can be seen that the event constituted a fine show, as well as being an interesting social réunion, and we congratulate the Finsbury students on their success.

An Electrically-Driven Gyrostat.—Mr. R. A. Fessenden, writing from Edison's laboratory, New Jersey, to the *Electrical World*, describes a gyrostat in which the motion is obtained from small electric motors fitted directly to the shaft of the revolving parts. One of the peculiar advantages of the electric motor is that it can supply power to a shaft which is itself in no fixed relation to a base, without adding unduly to its weight, or interfering with its motion, and this fact he takes advantage of in constructing a gyrostat which can be given practically continuous motion. The gyrostat has two heavy revolving discs, rotating in opposite directions. On the shaft of each disc is a small motor armature, and the pole-pieces are rigidly attached to the circular frame of the gyrostat. Current is received through the base by very flexible wires. This apparatus affords a means of obtaining very steady motion on board a vessel, or in any similar position. It may be used for taking lunar observations, where greater accuracy is required than with solar observations; also for the photography of eclipses, etc., at sea, and for artificial horizons. The gyrostat may also be used on torpedo boats or dynamite cruisers for sighting the guns. The gyrostat is placed in the conning tower, and the officer in charge sights the shaft, which may be hollow, at the object he wishes the shot to take effect on. Attached to each extremity of the shaft is a rod, so arranged that when the axis of the torpedo tube or gun is parallel to the shaft they complete a circuit, which explodes the charge. The rear rod may be lengthened or shortened to suit any range. The advantage of using the gyrostat is that the officer may take his time to sight the shaft, as the rotation of the gyrostat renders it independent of the motion of the vessel. The idea of using the gyrostat on board ship, says Mr. Fessenden, is not new. Piazzi Smythe observed the transit of Venus with one, but on account of the difficulty in giving it steady motion, it was very complicated and costly. The electrical form of the instrument might be made for less than £20. The *Electrical World*, in commenting upon this, suggests that this continuous gyrostat would solve the difficulty of the mariner's compass, maintaining, as it would, a true north position, independent of the motion of the vessel. If successful, it would possess a distinct advantage over the magnetic needle by not being subject to the variations to which the latter is subject, and in time might supersede the use of the magnetic needle entirely.

The Alexandra Palace Telpher Line.—The new telpher line at the Alexandra Palace promises to be one of the electrical triumphs of the year. Not only will the trains run at two-minute intervals, carrying some 1,000 passengers an hour (the contract stipulates a minimum of 750), but beyond this the gradient is an extraordinarily steep one, especially for a railway running without cogged rails, being not less than one in eleven, considerably steeper than Highgate-hill. The line, which runs from Wood Green Station to the Palace, is nearly half a mile in length—650 yards is the exact length—with a curved terminus at the end to allow the trains to return without detaching the locomotives. The line is a rigid one, consisting of two rails, the up and down lines, carried about 25ft. above the ground, on rows of stout double posts strongly bolted and braced together These posts carry transverse pieces at the top, furnished with iron plates, to which the rails are bolted. The rails are heavy ordinary rails with heads or rolling surface of circular section. The train is to consist of five carriages, and each of these to hold five persons, slung like a long garden seat, with its back to the posts, boxed in somewhat like a cab for five would be, and properly guarded at its ends and in front. The locomotive weighs, with the driver, about 21cwt. The driver sits on top as he would on a tramcar, and controls the switches and the automatic break; the passengers, of course, will hang down below the line, but still, at some distance above the ground, carried along amongst the tree-tops. The locomotive is capable of exerting 15 h.p., and draws the weight of five tons at six miles an hour. The difficulty chiefly to be encountered was that of obtaining sufficient frictional contact for the steep gradient. The ordinary rolling friction of locomotives can be taken as about 350lb. per ton. This, when the locomotive only weighs a little over one ton, would not be enough, and the system of wedge contact has been employed, as equally effective and not so expensive as the ratchet gearing often employed for steep railways. In this system, the circular head of the rail fits fairly tightly into the grooves of the driving wheel, which are tapered at an angle of 60deg. This is found to give a grip of 1,000lb. per ton weight of the locomotive. The Alexandra Palace is taking on a new lease of activity under the organising management of Mr. Lee Bapty, of Manchester and Glasgow exhibition fame, and the aerial telpher line, the first electric overhead passenger railway in England, will no doubt add greatly to its success, and secure to the telpher company a large share of public notice. The enterprise is being carried out for the Mines and General Telpher Company, of 15, Great George-street, the work is being done by the United Electrical Engineering Company, who are the contractors to the telpher company. It is hoped that the line will be ready to open on Whit Monday, in which case the whole work will be carried out within five weeks. This could only have been done by reason of the complete organisation of manufacture of the different parts by the United Co. and the companies working in conjunction with them. The building of the telpher locomotives, the dynamo, and the engines has been carried out by Statter and Co., at West Drayton, the switches, fittings, and small gear at the United Company's Jablochkoff works on the Albert Embankment, and the boiler being the only machinery having to be obtained outside. The present contract for the line is for three years, and the prices for passengers are to be 2d. for the up journey and 1d. for the down

WHAT IS THE CASH VALUE OF AN INVENTION?

BY SYDNEY F. WALKER.

Few problems are apparently more intricate than this. Every inventor naturally places a high value upon the child of his own brain; and there is a feeling generally prevalent that what an invention does or will fetch is dependent on something very like caprice. And so it is in a great many cases, because, too often, the purchaser of an invention does not intend to work it; he has merely taken it up as a speculation, hoping by its means to extract from others a handsome remuneration for the temporary use of his or someone else's capital.

In a great many cases, however, it should be possible to arrive at an estimate sufficiently accurate for business purposes.

Inventions may be broadly divided into two classes. Those which consist of improvements in apparatus already in use, and those which bring into being for the first time entirely new apparatus, supplying new requirements, sometimes even to be themselves created by the advent of the invention.

The vast majority of inventions belong to the former class. Only epoch-marking inventions, such as the telephone, the incandescent lamp, and the phonograph, belong to the latter.

The principles governing the calculation are the same in each case, but the method of procedure is necessarily different, since the data available in the latter case are not so full as in the former.

The value of any invention, either to seller or buyer, is clearly the difference between two sums—viz., what profit is obtained from the sale or hire of the apparatus directly due to the use of the invention, and what money has to be expended in producing the apparatus and inducing business.

To take a somewhat common instance in electrical engineering, an improved form of dynamo, or an improvement in the construction of dynamos, of what value is it to a dynamo-maker?

First, the manufacturer must ascertain what he is to gain by the use of the invention. To be of any value at all, it must bring profit in one of three ways, either by lessening the cost of construction, by increasing the price obtainable without increasing the cost, or in a greater degree by increasing the business done.

Supposing that a dynamo-maker sells £5,000 worth of machines in a year, and that the invention offered him would enable him, either in reduced cost, increased price, or increased sales, or all these combined, to clear an additional £1,000 per annum. The next point he has to consider is, for how many years may he expect this, and will later years bring a larger increase? In estimating both the yearly profit to be derived from the invention and that of the increased profit in later years, a manufacturer will have to distinguish carefully between the natural increase that would accrue to his business, and that actually due to the invention. This, perhaps, is not a very easy matter, but in many cases it can be estimated nearly enough for practical purposes.

Then as to the time. The protection of an invention by patent, if the fees are paid, and if it is not upset by litigation, extends now for 15 years. Will he estimate for the whole period? Certainly not.

First, he must allow a certain period for getting to work. This may be six months, a year, or even two. Patterns have to be made, old stock worked off or converted, the invention made known. During this time the manufacturer will reap little or no benefit from the invention, while he will be expending money on it. Next, he has to consider how soon the invention may be superseded. Something still better may come out which, if he has the opportunity, he will be obliged to take up, or be pushed out of the market. It is possible also that if the invention is successful, some rival maker will discover that something similar was done or patented 50 years before, and he may be obliged to surrender a portion of his profit to save the rest. Or the apparatus may be rendered obsolete merely through the advance of the knowledge of the science.

Probably, therefore, for inventions of the first class, three years of the estimated profits would be a fair average; or, say, £3,000 in the present case.

What has he to put against this? First, the patent fees to at least the seventh year, as he may be obliged to keep them up even after he has ceased to reap much benefit from the invention.

Next, he has the cost of careful tests of new patterns, new designs, new machinery where necessary, and advertisements of the apparatus if he thinks it necessary; also the cost of converting his stock-in-hand, or the amount he may sacrifice if he decides to let it go cheaper, to prepare the way for the new pattern. He must either do this, or the new pattern will be longer coming into profitable play. Further, if he is wise, he must also add something for possible legal expenses in connection with the patent. If he has not actually to defend his patent, he may be put to some expense by either would-be infringers, or other holders of patents who would wish to have the invention he holds declared an infringement of theirs. The balance between the two sides of this account will represent the gross value of the patent. From this sum the buyer has to substract the discount for the one, two, three, and four years of the proportion of the net sum paid. Thus, if from the £3,000, at which the invention is valued, £1,200 has to be taken as detailed above, £1,800 remains the gross value of the patent; but as the £1,800 would only accrue in sums of, say, £600 per annum, the buyer should deduct a discount for two years on £600, the first year's money, assuming that he allows one year for getting to work, three years' discount on a second £600, and four years' on a third £600. The rate of discount will be the interest that the money would produce invested in his business, in other ways, say, in machinery, a branch office, etc. Thus, if his capital returns him 10 per cent. all round, he will deduct £120 + £180 + £240 = £560, leaving £1,260. If he pays this sum, assuming the estimate to be fairly correct, he will stand, at the end of the four years, exactly where he would have stood if he had not taken up the invention. Therefore, he will probably strike off a further hundred or two or more, according to his ideas, to pay him for his trouble and risk; and this reduced sum will represent to him the cash value of the invention. Of course, if instead of doing £5,000 per annum, the manufacturer had been doing £100,000, the invention should be worth to him at least 20 times as much, though it must be borne in mind that the cost of patterns, alterations, advertising, and litigation will also be very largely increased.

THE EXETER ELECTRIC LIGHT COMPANY'S CENTRAL STATION.

The Exeter Electric Light Company, Limited, having purchased a site in the New North-road, most suitable for the purpose, near the centre of the city, is now fitting up a central station for supplying electricity to hotels, shops, public buildings, and dwelling-houses. At first only the main business portions of the city will be supplied, but later it is hoped to carry the lines into the suburbs.

Permission for overhead wires having been obtained from the City Council, the mains will be supported on ornamental iron posts, erected in a line with the kerbstone on either side of the street. The Thomson-Houston system of arc lighting and the Mordey transformer system of incandescent lighting will be used. Current will be supplied at a definite price per lamp per annum, a charge of 10s. being made for each 10-c.p. incandescent lamp, the consumer to pay for lamp renewals. Arc lamps will be supplied at various prices, according to the hours during which the lights are used, the lowest price being £9 and the highest £13 per 1,200-c.p. lamp per annum.

The whole of the plant at the central station will be in duplicate, and will consist of two 105 h.p. Babcock and Wilcox boilers, working at 140lb. pressure, supplying steam to two compound horizontal engines by Messrs. Fowler and Co., Leeds, the engines each giving 125 brake h.p. at 90 revolutions per minute. The low-pressure cylinders are 24in. diameter, high-pressure cylinder 13in. diameter and 24in. stroke, flywheel 12ft. diameter. Two triple expansion Westinghouse engines by Messrs. Alley and Maclellan,

Digitized by Google

Glasgow, each engine giving 20 brake h.p. at 400 revolutions per minute.

The dynamos are two 75-unit Mordey alternators, with Victoria exciters coupled on to shaft, each machine being driven direct from the flywheel of the Fowler engine by means of eight ropes; speed 200 revolutions per minute, pressure 2,000 volts. Two 30-light Thomson-Houston machines, each belted direct on to a Westinghouse engine; speed 900 revolutions per minute, current 6·8 amperes.

The switchboard will be so arranged that, in the event of a dynamo or engine breaking down, the whole load may be instantly thrown on to the spare dynamo and engine. It is expected that the station will be completed early in July, when the supply of current will commence. At first the hours of lighting will be from one hour before dusk until 12 p.m. each night.

Contracts have already been obtained for lighting some of the principal hotels, and many of the leading shops and business premises.

The new theatre which is now being built is to be lighted by electricity, and it is hoped that the local company will get the contract for carrying out the installation; tenders for doing the work have been sent in.

It is probable that several churches will shortly be provided with the electric light. Altogether, the Exeter Electric Light Company has every prospect of doing a large amount of work, and there being plenty of space in the central station, additional plant will be put down as the demand increases.

ON THE SECURITY AGAINST DISTURBANCE OF SHIPS' COMPASSES BY ELECTRIC LIGHTING APPLIANCES.*

BY SIR WILLIAM THOMSON, D.C.L., F.R.SS. (L. AND E.), PRESIDENT.

The danger to be avoided is sufficiently explained in the following short statement by Mr. William Bottomley, which appeared in the *Nautical Magazine* for December, 1885:

"The following example of a case which might occur in any large ship will show the amount of error which may be produced on the compass" [by the electric lighting apparatus] "unless precautions are taken to guard against it.

"Suppose a main lead from the engine-room to the fore part of the ship, to light up 100 lamps, is brought along the centre of the ship. It may be at a distance of 10 metres, or 33ft., from the standard compass, and will run almost underneath it. If we suppose that each lamp takes one ampere of current, there will be a current of 100 amperes altogether in this lead. Now, the effect" [of an infinitely long straight current] "on the compass" [above it] "at a distance D in centimetres is given by the formula

$$F = \frac{2 \times \frac{1}{10} C}{H D},$$

where C is the current in amperes and H is the horizontal magnetic force. In this case we have C = 100 amperes and D = 1,000 centimetres. Therefore,

$$F = \frac{20}{1{,}000\,H} = \frac{0{\cdot}02}{H}.$$

At Glasgow the horizontal force may be taken as 0·15 in C.G.S. units; therefore the effect on the compass will be $\frac{\cdot 02}{\cdot 15} = \frac{1}{7{\cdot}5}$. This will be expressed in degrees by multiplying by 57·3 the number of degrees in the radian, or angle subtended at the centre of a circle by an arc equal in length to the radius. Therefore, the amount of error produced by such a current on the compass will be $\frac{57{\cdot}3}{7{\cdot}5} = 7{\cdot}6$ degrees.

"The foregoing refers to a single wire and a continuous-current machine; but if an alternate-current machine is employed, no effect will be produced on the compass, even when the ship's side is used for the return. When a continuous-current machine is used, the danger of producing an error on the compass can be avoided by using two wires close to one another, but these wires should be well insulated from the ship's side. If in any way" [two points of] "one of the wires is brought in contact with the iron of the ship, there may be no change observable in the lighting, but the current may produce as much error on the compass as it would if there was only a single wire.

"The following points should therefore be attended to in all cases of lighting ships by electricity: First.—With continuous-current machines two wires, well insulated, should always be employed. Second.—The insulation of the wires should be tested periodically; if any connection with the iron of the ship is found, the fault should at once be made right. Third.—When an alternate-current machine is used, a single wire may be employed, and the iron of the ship used to complete the current without producing any effect on the compass.

"What makes this question of the greatest importance is that the error may be produced without ever being detected by the officers of the ship. On board ship the errors of the compass are usually determined during the day, in the morning and afternoon, but the electric light is only used at night. The captain may therefore carefully determine his errors every day, and set his course quite correctly; but at night, when the electric light is turned on, the ship may be going several degrees off her proper course, although she is being correctly steered by the compass.

"In connection with the lighting of ships with electricity, there is another point which should also be attended to—that is, the position of the dynamo. If it is placed near an iron bulkhead, the upper end of which is near the compass, the bulkhead may become magnetised by induction so powerfully that it will produce a considerable error on the compass."

The subject was also referred to in Mr. Bottomley's paper on "The Magnetism of Ships and the Mariner's Compass," read before the Society of Arts, January 28, 1886, and published in the *Journal* of the Society for February 5, 1886. In the discussion which followed, and in which Captain Creak, of the Admiralty Compass Department, Mr. Alexander Siemens, and Dr. Hopkinson took part, it appeared that in three ships lighted on the single-wire system with direct currents, small but not unimportant errors in the compass, due to the lighting currents, had been actually observed. Since that time several cases have been reported to me of large passenger ships, lighted with direct currents on the one-wire system, in which as much as 4deg. or 5deg. of error on the compass has been produced by the electric lighting. In the latest of these cases, a few weeks ago, an error of 4deg. on the north course was found when the light was put on. The light was put on and off several times with the ship's head north, and every time the same error was produced.

The precautions for security which I have to suggest are—

1. The use of the two-wire method exclusively (unless, which is now rarely the case, alternate currents are used).

2. A differential galvanometer on the two mains for the lighting current to show approximate enough equality of the outgoing and incoming current. A rough and cheap instrument (on the old telegraph "detector" plan) would, I believe, suffice, and would be valuable for the electric lighting system (independently of the compass question) to give timely warning of any faults or accidental contacts or failures of insulation sufficient to cause any considerable difference in the strength of the currents carried by the two mains.

3. Care that there is not magnetic "leakage" from the dynamo (as practical men, guided by Faraday's ideas, theory and language, have now taught the scientific world to call it) enough to produce any compass disturbance of practical moment. Capt. Creak, speaking at the end of 1885, in the Society of Arts discussion previously referred to, said that in one ship the direct compass-disturbance produced by the generating machine was "felt through a distance of 55ft.," and across iron bulkheads, and that it

* Paper read before the Institution of Electrical Engineers, May 23.

Digitized by Google

was perceptible also in other ships of the Royal Navy electrically lighted on the two-wire system. My impression is that the improved dynamos now made have much less of magnetic leakage than those made prior to 1886, but we still want information as to their disturbing magnetic effect at such distances as have to be considered in connection with the compass question.

4. To ascertain that there is no perceptible compass-disturbance, or if there is any to test its amount, the compass should be observed while the current through the dynamo is started and stopped, either by starting and stopping the dynamo itself, or by making and breaking the circuit of the field-magnets. This should always be done before the electric light installation is taken over from the contractors. It is best and most easily done when the ship is in dock, or lying steadily at anchor. On no account ought it to be delayed, in a new ship, till she goes out for compass adjustment. A determination of the amounts of the disturbance (if any) for all courses of the ship can be made by aid of my deflector without moving the ship. But a sufficient practical test may be made by first observing the effect of starting and stopping the current, on the compass as it stands; then adjusting a small magnet placed on, or supported a little above, the glass of the bowl, to deflect the compass about 45deg. first on one side and then on the other side of its undisturbed position, and in each case observing the effect of starting and stopping the electric current. This effect ought not to be as much as 2deg. in any of the three cases.

5. A small electric lamp may safely (and with very great advantage in most cases of electrically lighted ships*) be used to light the compass. The effect, if any perceptible, of its current on the compass ought to be tested in the manner described in No. 4.

Discussion.

In opening the discussion, **Capt. Creak** said he was glad Sir William recommended the two-wire system, for that in itself was a great safeguard against disturbance. So far as his own experience went, most trouble arose from magnetic leakage due to the employment of machines having considerable external field, and placing them in positions with respect to the iron of the ship that such field was directed towards the compass. In one case (H.M.S. "Northampton") where three such machines were used, an error of 11deg. was produced when all the machines were running, and three correction tables were necessary.

Mr. Alex. Siemens, as an advocate of the single-wire system, thought it quite unnecessary to use two wires, for in all his experience, extending over many ships fitted on the single-wire system, only one instance had occurred in which complaint was made, and in this case the wiring was done before the position of the compass had been decided upon, the spot eventually chosen being in close proximity to the leads. As a proof that the single wire system could be made satisfactory, he mentioned that his firm make enquiries on all vessels fitted by them every time they came into port, in order to ascertain whether any inconvenience arises from the electric lighting apparatus, but with the exception above quoted no complaint has been made. Referring to Mr. Bottomley's letter mentioned in the paper, Mr. Siemens said the screening effect of the decks had been entirely neglected in the calculations there given. A second case of disturbance had come under his notice by his being asked to inspect a ship fitted by another firm, and the maximum deflections produced were ½deg. and 1½deg. on the standard and steering compasses respectively. As regards the position of dynamos, he had found no appreciable effect at distances greater than 50ft.

Prof. G. Forbes, speaking of H.M.S. "Northampton," said that the dynamos referred to by Captain Creak were placed in an iron room, and still the disturbance produced was very serious. From an examination of machines of the type there employed, he found that the leakage mainly comes from the parts of the yokes near their junction with the cores; but he had reason to believe that in the more modern machines the leakage has been considerably reduced.

Prof. Jamieson mentioned the case of the ss. "Bombay," in which the steering compass was disturbed 9deg. The fault was traced to a wire about 4ft. from the compass, and remedied by running a return wire.

Mr. Raworth, in corroborating Mr. Siemens with regard to the great convenience of the single-wire system, gave additional details respecting the second case mentioned by Mr. Siemens. The compass was influenced by either of two conveying wires running along lower passages, according as the needle was parallel to one or to the other. On examining the decks, the iron was found cut away between the wires and the needle, and the defect was remedied by enclosing the former in 3in. iron pipes.

Major Cardew described his experience in lighting binnacles electrically as suggested by Sir W. Thomson in his note, and although he carefully twisted the leading wires together the filament seriously affected the compass and readings.

Sir W. Thomson, in reply, said that caution was necessary in arranging lamps for lighting compasses, and in answer to Prof. Forbes, expressed an opinion that alternate currents if used in such lamps would not demagnetise the needles. Referring to the screening effect of decks, he pointed out that Captain Creak's observations proved them to be of little use in neutralising the external field of dynamos, and to be efficient the iron required to be very thick. The decks may, however, considerably reduce the action of currents on the compasses, especially where the circuits are completed between two decks, but when the wires pass from one deck to another, the screening effect is much reduced. Although the conductors in the single-wire-system may be placed so as not to affect either one of the two compasses generally used, yet it is very difficult to arrange that neither are disturbed, and as any disagreement between the two (especially as the difference may vary with the portion of the ship being lighted) further complicates the navigation, Sir William felt sure it would be far the best plan to adopt the two-wire system in all cases.

The discussion on Mr. Mordey's paper on "Alternate Current Working" was deferred till the next meeting on May 30.

* Those who know the trouble of keeping the best of ordinary compass lamps alight, for the steering compass on the bridge of some of our cross-Channel steamers in a winter gate, will appreciate this advantage.

THE EFFICIENCY OF METHODS OF ARTIFICIAL ILLUMINATION.*

BY EDWARD L. NICHOLS, PROF. OF PHYSICS IN CORNELL UNIVERSITY.

(Continued from page 378.)

The spectrum of rays reflected from the face of the magnesium carbonate, however, contains in proper proportions the light from all portions of the source, and one of the chief sources of error to which spectro-photometric work is subject is thus eliminated.

The investigations made with this instrument, which have been described in a paper read before the American Association,† included the measurement of candle flames, and of various petroleum and gas lamps, also of the limelight, the incandescent lamp under a wide range of conditions, of the electric arc, and of daylight by clear and by clouded sky. The results obtained illustrate the precise character of those differences in composition to the bearing of which, upon the study of the efficiency of artificial illumination, I desire to call your attention.

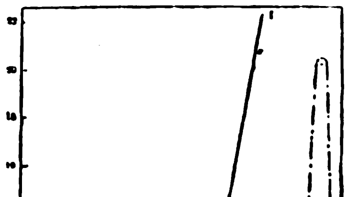

Fig. 8.

In the first place, it was found that the light of the candle, and of oil and gas flames, although subject to considerable fluctuations from variations of the condition under which combustion occurs, but differ slightly in quality from each other and from that of incandescent lamps maintained at normal candle-power. The incandescence material in all is carbon, and it is a significant fact that the average temperature of incandescence is nearly the same in all luminous flames, and that the

* Paper read before the American Institute of Electrical Engineers, March 12, 1889.

† Edward L. Nichols and W. S. Franklin. "A Spectro-Photometric Comparison of Artificial Sources of Illumination." Paper read before Section B., A. A. A. S., at the Cleveland meeting, August, 1888.

Digitized by Google

highest temperature, until very recently at any rate, at which it has been found practicable to maintain the carbon filament of the glow lamp, is very nearly that at which the same material exists under the most favourable conditions in oil and gas flames. Hence it is that the radiant energy per candle-power, as has been shown by Julius Thomsen, is nearly the same for all these flames.

Passing to other sources of illumination, such as the lime light and the electric arc, we find the entire portion of the spectrum lying beyond the yellow increasing more rapidly, regions of longer wave-length than the yellow increasing less rapidly than the candle-power, the rate of increase growing steadily as the wave-length diminishes from the red to the violet end of the spectrum. Fig. 8 shows the results of comparisons of the spectra of the lime light, electric arc, and of daylight, by clear and by unclouded sky, with that of an incandescent lamp maintained at its normal candle-power. This lamp, which was chosen as a standard of comparison, was an Edison 16-candle, 100-volt lamp. Its light was precisely similar to that of a "Board of Trade" argand gas-burner, showing the same relative brilliancy throughout the whole of the visible spectrum. The measurements were made with the spectro-photometer just described (see Fig. 10), the light in every case falling upon the block of magnesium carbonate, and entering the slit of the spectroscope after reflection from the face of the latter. For purpose of comparison, the brightness of the standard incandescent lamp has been taken as unity throughout the spectrum. If we make a diagram in which abcissæ are wave-lengths and ordinates, intensities, referred

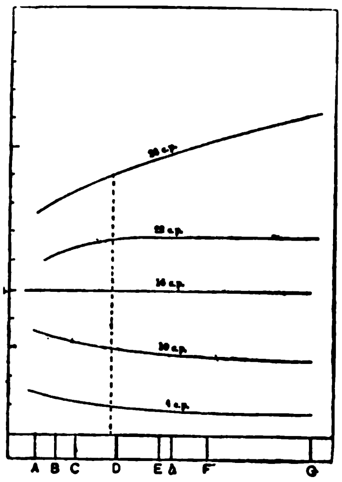

Fig. 9.

to that of the standard as unity, the curve for this lamp will be a straight horizontal line, with ordinate = 1.

All other spectra are reduced to the same brightness in the region of the D line of Fraunhofer, and their brightness in other regions, referred to that of the corresponding wave-length in the spectrum of the standard, is shown by means of curves.

Observations were made in 10 regions of the spectrum, equi-distant as to wave-length, and embracing the whole of the visible spectrum. It will be seen by reference to the figure that the lime light is relatively much stronger in the violet, and much weaker in the red than the standard. In the arc light this increase of intensity toward the violet is even more marked, but its variation in quality from the lime light is by no means so great, as its exceedingly brilliant, bluish-white appearance to the eye would lead us to expect. The source of that appearance and of the very high actinic value of the arc is found, however, in the presence of an exceedingly bright band in the extreme violet. Here the relative intensity of the arc light spectrum rises abruptly about three to 20 times that of the incandescent lamp.

Measurements were made upon a long arc lamp with ½in. carbons, with 10 amperes and 50 volts, and a short arc lamp with a 20-ampere current. The character of the light was found to be almost identical excepting in this light band in the neighbourhood of the G line, which is much more prominent in the long arc lamp. The character of the light was found to be much the same at all angles below the horizontal plane.

The only other spectro-photometric measurements of the electric arc with which I am acquainted, have been made upon the Foucault regulator, a lamp with carbons of small diameter. Fairly concordant determinations of the distribution of intensities in the spectrum of this lamp by W. H. Pickering*, H. C. Vogel†, and Crova‡ show that the light of this lamp is decidedly bluer than that of the lamps with large carbons in vogue at the present day, the spectrum of the former being about five times as rich in the violet as that of gas or oil flames. Mr. Nakano's results, of which mention has already been made, indicate marked increase in the efficiency of the arc lamp as the diameter of the carbons is decreased; and since increase of efficiency arises from a higher average degree of incandescence, we should expect just such an increment in the shorter wave-lengths as shows itself in the case of the Foucault regulator.

Finally, in the case of daylight, we find the intensity of the shorter wave-lengths exceedingly great as compared with that of any artificial source of illumination. If the spectrum of daylight be brought into comparison with that of an incandescent lamp, and the two be reduced to the same intensity in the yellow, the extreme red of the daylight spectrum will be so dim in comparison with that of the lamp, as to render measurements difficult. In the violet the discrepancy will be just as marked, the sun's spectrum being relatively of enormous brilliancy. Curve I., Fig. 8, shows the result of such a measurement of the daylight spectrum, taken just after noon upon a cloudless summer day.

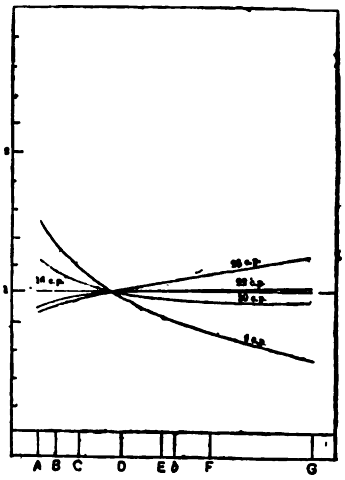

Fig. 10.

Vogel has given data of a determination in which the preponderance in the violet was even more marked, the relative intensity of daylight for the region corresponding to wave-length 4,260 (just beyond the G line), being 100:1 for spectra, which were equally bright in the neighbourhood of the D line.

Ordinarily, there is considerable absorption of the blue and violet by moisture in the atmosphere, and a measurement of daylight under a densely-clouded sky gave curve II. Even under these conditions, with the violet reduced to about one-tenth of the value which it possesses in clear weather, daylight is very much bluer than any artificial light. The light emitted by burning magnesium approaches more nearly to it than any other, being, according to Pickering, considerably stronger throughout the blue and violet than the light from the Foucault arc lamp. Its colour, however, is not reinforced by a violet band like that in the spectrum of the electric arc, a region which by its extraordinary brightness has marked influence upon the colour of the light.

These variations depend upon temperature primarily, and they may be studied to the best advantage in the spectrum of the incandescent lamp. The radiating surface of such a lamp is at a nearly constant temperature through out, and it may be given a very considerable range in the matter of incandescence, involving variations in colour and total intensity, which are under complete control.

(To be continued.)

Other Places	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

Although the Paris Exhibition is open, the major portion of the exhibits are in so backward a state that any systematic description is almost impossible at present, so we shall wait a short time till the chaos of packing cases becomes a neat arrangement of exhibits. It is needless to tell our readers that—so far as our description of the electrical exhibits is concerned—our attention will, in the first place, be directed to the interests of English and American exhibitors. A special edition of this paper, with the report of the exhibition in two languages—English and French—will be obtainable in the Exhibition.

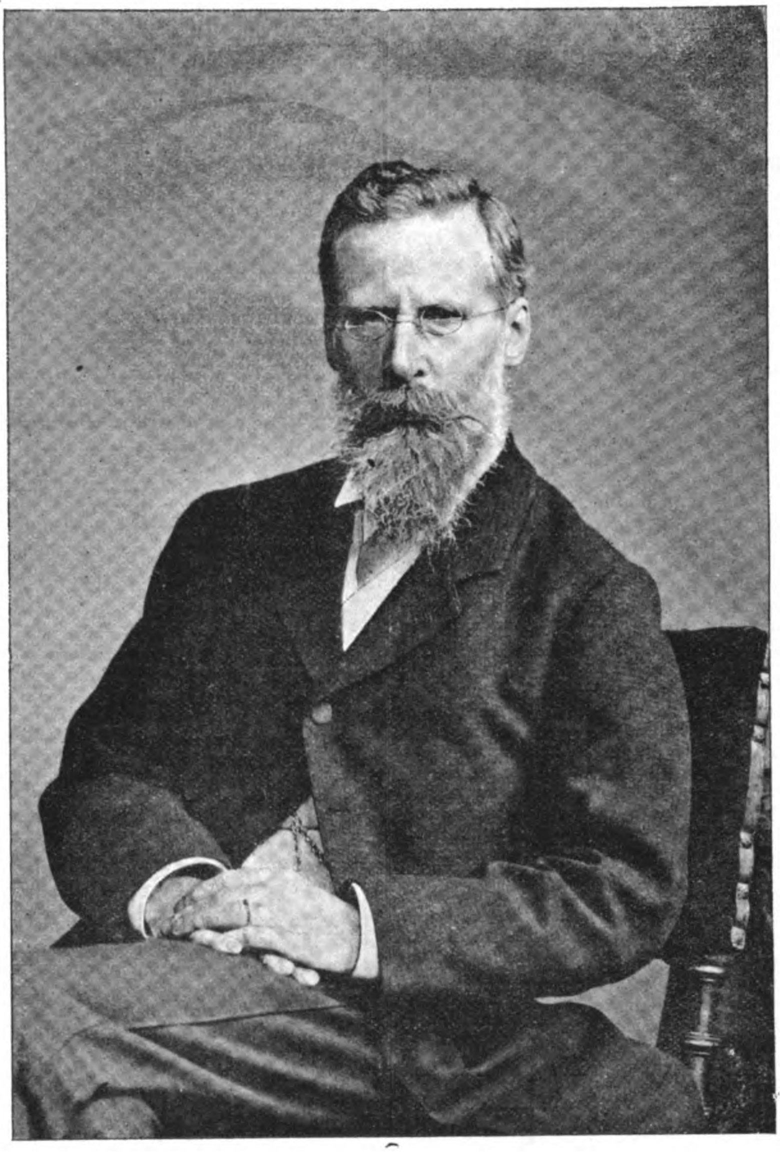
SHIP LIGHTING.

The paper or note of Sir Wm. Thomson read and discussed at the Institution of Electrical Engineers last week brought forward one of the most important practical questions that the electric light engineer has to deal with. The result of the discussion was somewhat unsatisfactory, inasmuch as the differences of opinion were not absolutely settled. The problem is a simple one and can be presented without verboseness. It is admitted on all hands—that is, by the opponents as well as the advocates of general electric lighting—that this kind of lighting is admirably adapted for use on board ship. So far as we know, assuming no danger of breakdown in the apparatus used, the only real objection ever urged against the use of electric light on board ship has been the possibility of unrecognised action upon the compasses leading to disaster. If all possible errors of the compass are known, it is not difficult to make the necessary corrections and to steer correctly. A pure landsman never can recognise, and, in fact never does recognise, the absolute necessity of knowing all about his compass to a sailor. He begins to recognise the real value of this knowledge when on board ship, off a dangerous coast in a thick fog. The lives of all on board and the safety of the ship then depends solely on the correct knowledge of the compass errors. The introduction of any magnetic action, or action from electric currents, as is the case in the use of electric lighting apparatus, brings influences into play which affect the compasses, the action upon which, therefore, should be fully known. It is usual to consider two sources from which the compasses may be affected—the currents traversing the wires of the circuits or lamps, and the straying lines of magnetic force which, like individuals of a romantic turn of mind, often go where they ought not to go. With regard to the latter, as our knowledge of the proper construction of dynamos increases, and if the mechanical construction is carried out in accordance with this knowledge, the wandering lines decrease, and, at any rate, the difficulties arising from this source are easier compensated than the other. The greatest attention, therefore, has been paid to the action of the currents in the wires, and two schools of practicians have arisen, the one advocating a double-wire system, the other a single-wire system. The former may be dubbed the theoretical practicians, who are more theoretic than practical, while the latter are almost wholly of the practical. The advocates of the single-wire system contend that experience shows perfect safety when the work is properly done, and the perfect practicability of screening the compasses from evil effects of the current. The theorists say the screens will not act. The practical men laugh at theory and point out the actual fact that the iron tube does screen, hinting that theory

Digitized by Google

may be wrong, while the facts remain facts. To the outside world the discussion of the question remains in the state we have mentioned, two sides, two systems, not in accord; but as to the future we may safely predict the two-wire system a thing of the past, that most of the work now done is on the one-wire system, and this kind of work will increase till its rival has no place in ship lighting. This conclusion is directly opposite to the first suggestion of Sir William Thomson, that where continuous currents are used "two wires well insulated should always be employed."

We are glad that Sir William Thomson has again called attention to the possibility of errors being overlooked because the errors of the compass are usually determined during the day, when the electrical apparatus is not in use. To ascertain the compass disturbance is a simple matter. Sir William says, "a sufficient practical test may be made by first observing the effect of starting and stopping the current on the compass as it stands, then adjusting a small magnet placed on, or supported a little above, the glass of the bowl, to deflect the compass about 45deg. first on one side and then on the other side of its undisturbed position, and in each case observing the effect of starting and stopping the electric current. This effect ought not to be as much as 2deg. in any of the three cases."



WILLIAM CROOKES, F.R.S.

THE ELECTRIC COMBINATION.

Rumours have come to our ears for some time back with reference to the immense electric combination, negotiations about which have been quietly proceeding, but nothing very definite could be said. Now, however, that the affair will probably be out and put before the public within a very short period, some more exact idea of what is pending may perhaps be given. The undoubted success of Sprague in America, and of the proved satisfactory nature of accumulator traction for tramways at Birmingham, has aroused the tramway companies and the manufacturers who supply them to a keen sense of the probable direction of future work in suburban traffic in England; and to safeguard these interests, as well as to unite in a common aim some of the leading men in electrical engineering, both to avoid competition and from a financial point of view, is, we may take it, the idea of the combination. The firms who will probably join in the combination are the Electrical Power Storage Company, Elwell-Parker, Limited, the Sprague Company, the Julien Company, Hammond and Co. (the House-to-House Co.), the Falcon Engine and Car Works, and some of the large tramway companies are also mentioned. The title of this gigantic company, as far as has been settled up to the present, will be the Electric Works Construction and Maintenance Company. This title has already been registered as the Construction Department of the House-to-House Company, and will be taken over together with that part of the business of the House-to-House Company. The main work of the company is intended to be the construction of electric plant and machinery, and the carrying on of electric traction work, both for tramways and also for heavier electric railways. It is also intended to establish central stations in the provinces for distribution of light and power. The financial part of the undertaking is, as can be imagined, the most serious part of the negotiations, and a very large capital will

Digitized by Google

be required. It is understood that the shares in the E. P. S. Company will be bought up at par value, and the shareholders at their discretion can have the whole value of their money returned. The tendency to these gigantic combinations is evidently taking deep root in English soil, and the result of the movement, whichever way it proceed, will undoubtedly have a very large effect upon the electrical engineering profession.

W. CROOKES, F.R.S.

William Crookes is another of our vice-presidents whose presence confers honour upon the Institution of Electrical Engineers. He has long made his mark, and attained the blue ribbon of science (the Fellowship of the Royal Society) from his chemical and physical researches. Of late years he has paid great attention and given deep study to the subject of molecular physics. His *confrères* in the chemical world have paid him the honour of electing him President of the Chemical Society, a society that ranks almost, if not quite, on an equality with the Royal in the estimation of its members.

Mr. Crookes is a Londoner, born in 1832, entering the Royal College of Chemistry in 1848 as a pupil of Dr. Hofman, whose little book on chemistry should be carefully read by every electro-chemist and electro-metallurgist. In 1849 Mr. Crookes gained the Ashburton scholarship, and next year became junior assistant to Prof. Hofman, subsequently becoming senior assistant, which position he retained till 1854, when he obtained the appointment of superintendent of the meteorological department of the Radcliffe College, Oxford. The list of papers on scientific subjects that Mr. Crookes has contributed to the various societies or to periodical literature is a lengthy one, and the investigations described therein are mostly of a practical character. Mr. Crookes is the author or translator of several works on chemical and metallurgical subjects. It will be seen that he must of necessity be fully cognisant of the chemical literature and progress of the last quarter of a century when it is stated that in 1859 he founded *The Chemical News*, and that he is still the editor and proprietor of that paper. The introduction of incandescent lamps, perhaps, brought Mr. Crookes's name prominently before electricians, because the value of these lamps depends largely upon the perfection of the vacuum, and his investigations upon "Molecular Physics in High Vacua," published in the Royal Society's *Transactions*, came just at the time when men's minds were exercised on the question. Another interesting paper at this period was in the form of a lecture delivered before the British Association, when, under the title of "Radiant Matter," he gave a *résumé* of his investigations on electric discharge in high vacua. In 1880, the French *Académie des Sciences* bestowed on Mr. Crookes an extraordinary prize of 3,000f. and a gold medal, in recognition of these discoveries in molecular physics and radiant matter. Two years since, Mr. Crookes was president of the Chemical Section of the British Association, and in his address he struck another note, contending from reason and experiment that the so-called chemical elements are really compound bodies, and his presidental address to the Chemical Society was a continuation of this subject.

GASTON PLANTE.

We regret to chronicle the death, at Paris, of M. Gaston Planté, whose name has been familiar to electricians for many years past. To M. Planté, in a great measure, is due the development of accumulators. His experiments with lead, and the results obtained therewith, led others, notably in the first instance M. Faure, to attempt something giving greater perfection with less loss of time. M. Planté was at one time chemist to the firm of Christofle et Cie., the well-known electro-metallurgists, and his work there led him to study the phenomenon of polarisation, and to the construction of his well-known type of secondary battery. It has always seemed to us that M. Planté approaches somewhat to the type of the ideal man of science. He was more at home in his laboratory than amid the whirl of the busy world, and for the most part was content to live a very retired life. Many of our readers have, however, from time to time met M. Planté either during the bustle of exhibitions or in the quieter social life, where at all times they would find him ready to listen and ready to give from the large fields of his experience. Of late years his health has been exceedingly precarious, and his kindly face will be missed by many who hoped to have had a friendly greeting from him during this exhibition year. He was the author of several books and many pamphlets on his favourite subject, some of which have been translated into English.

Electric Water Indicator. — Mr. G. Jennings, Lambeth, has recently obtained contracts for fitting electrical apparatus for indicating the level of the water in the reservoirs of the water works companies at Weston-super-Mare and at Bristol.

CORRESPONDENCE.

FIREDAMP DETECTORS AND ELECTRIC MINERS' LAMPS.

To the Editor of The Electrical Engineer.

Sir,—By the tenor of Mr. Sydney F. Walker's letter, I take it that he imagines that the active materials we employ in our detectors are liable, under certain conditions, to become at least red hot. I may say that so far we have not, under any circumstances, attained a higher temperature than 250deg. F.

I am well aware that explosions may be and have been caused by air containing an explosive percentage of gas being caused to pass rapidly through the wire mesh of a so-called safety oil lamp. I imagine that under these circumstances the oil flame partakes of the nature of a blowpipe flame, which, when impinged with violence upon one portion of the protecting gauze, supplies heat to that part with greater rapidity than it can be carried off by conduction and radiation, and it thereby causes the gauze to become sufficiently heated to induce violent combustion in the surrounding air.

As firedamp and air even in their most explosive proportions require a higher temperature than a red heat to cause rapid ignition, I doubt very much whether an accidental breakage of the glass bulb of a good electric glow lamp would induce an explosion even in a very dangerous atmosphere. I now allude to a well-made and thoroughly exhausted glow lamp, such as those now used in the best forms of electric miners' lamps. Those conversant with the manufacture of incandescent electric glow lamps are well aware that a short and thin carbon filament, which, if heated by the current in air will only emit a dull red heat, will give out, with the consumption of the same amount of electrical energy, a brilliant white light when enclosed in a good vacuum. The difference of light is still more marked if hydrogen or some of its compounds are used instead of air. The explanation is, that air and many other gases are good absorbents and conductors of heat, while a vacuum is a very bad conductor. For these reasons I apprehend no danger from the breakage of these small glow lamps in mines. The mass of air, or mixed air and gas, would instantaneously carry off the small amount of heat contained in a carbon filament not more than a quarter of an inch long, and of about the sectional area of a human hair.

I quite agree with Mr. Walker when he states that a gas detector should be placed in the hands of every working collier, not only for the safety of the mine, but from a hygienic point of view. The indicator should give an aural or visual indication, it should be certain in its action, and to be certain it must be simple. To be of real service it ought to be automatic, and, if possible, it should be attached to the lamp. It is with this end in view that we are now working.

There can be but little doubt but that in the not very far and distant future all working in our coal mines will be carried on by aid of the electric light—probably a combination of fixed and portable lamps. In attempting to meet the requirements of miners, many difficulties will have to be overcome. We are asked to supply lamps which shall be:

1. Absolutely safe in an explosive atmosphere.
2. They should give a far better light than any of the oil lamps now in use.
3. The duration of light with one charge must be from eight to ten hours.
4. They should be easily and quickly charged, and should require no skilled labour or attention.
5. They ought not to be too heavy, or clumsy in shape.
6. They should be so constructed that they would safely stand on the roughest ground, and should be capable of being suspended on a hook.
7. They must be made to burn in any position, and should be unspillable.
8. There must be no loose or exposed contacts, and everything should be quite water and dust tight. The light must not be liable to be extinguished by a jerk or any concussion in the air. Again, the materials used in the construction of the lamp should be sufficiently strong to withstand such little freaks of the colliers as using it as a mallet to drive a peg or hook into the coal or wooden support whereon the lamp may ultimately be suspended, or to be used a stool for the miner during his meals. The last-named purposes scarcely enter into the general calculations of the lampmakers, but as I have seen them being used for these purposes, I should think it wise to make the lamp-cases sufficiently strong to withstand such usage.

The position in which the lantern should be placed seems a very vexed question. Many miners insist upon its being placed on one of four sides—say, of a square lamp—so that the light is cast well forward; others say that it would be better to fix it on one corner, thus throwing the light both in front and sideways as well. Again, some suggest placing it on the top so that it would well illuminate the roof, which they look upon as the most fruitful source of danger. Others maintain that the light should be placed at the base of the battery so as to bring it as near as possible in the same position as the oil lamp, because the men have been used to the light in that position.

Lastly, but not least, the lamp should be durable, and cheap, and the cost of supplying the daily requisite amount of electrical energy must be small.

I am aware that Mr. Walker has had some considerable experience in the electric lighting of mines. I should therefore like to get his opinion as to the best position for the lantern on a combined portable battery and lamp.—

Yours, etc., J. T. Niblett.

May 29.

ALTERNATE CURRENT WORKING.*

BY W. M. MORDEY.

(*Continued from page 422.*)

Now, I am prepared to take a precisely similar stand with regard to alternators, and to submit for your criticism the view that a perfect alternator for any and every purpose should have no resistance and no self-induction.

I prefer to regard the question of alternate-current parallel working as a question very largely depending upon what are the best principles of construction for synchronising alternate-current motors. It is very much better and simpler to look at it from this point of view than from any other, and I venture to assert, in spite of all that has been said to the contrary, that if alternators are made, amongst other things, with the least possible self-induction and the lowest practicable resistance, they will not only be the best alternators, but they will best run parallel, and will do so because they will then be the best synchronising motors.

I think that even the advocates of large self-induction will admit that that quality does not improve an alternator *per se*, they only introduce and tolerate it on account of its supposed bearing on parallel working (I could quote a number of such admissions), but it appears to me that, properly regarded, self-induction is not even a necessary evil—it is an unmitigated evil. It is an evil even for this narrow and restricted purpose.

What does it do? When machines are getting out of phase, it steps in and prevents that ready transfer of current which is required in order to check the leading machine, and to accelerate the lagging machine. It prevents the latter from immediately and unhesitatingly developing those motor properties which lie at the root of successful synchronism. The foundation of parallel working should be that the prime motors are under the control of the generators. The question turns, therefore, partly on the qualities of the prime motor, but much more largely on the motor qualities of the alternators.

I am prepared to admit that if the tendency of the prime motor to lead or to lag is so great that under no circumstances can it be controlled—and this may arise either from excessive power on the part of a prime motor, or from defect of motor power in an alternator—then large self-induction or resistance may be of use in order to prevent one or more of the machines being burnt up, not, however, as useful and not as effective as a safety-fuse; but self-induction under such circumstances is not an assistance to parallel working. Quite the contrary. If it were absent, probably the machines would run parallel all right. They would be much less likely to be burnt up without self-induction than with it. Self-induction is useful because it prevents the machine which ought not to have it from being burnt up because it has it.

Now, I will briefly describe some experiments with two of my alternators, each made for 2,000 volts, and each capable of working continuously at 35,000 to 40,000 watts, or, say, 50 e.h.p. output.

Arrangement.—Each machine was driven by 75 i.h.p. Fowler engine. These engines were similar, their normal speed of working being 120 revolutions per minute. Each of the engines, which were

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

not coupled or connected in any way, was provided with a heavy fly-wheel, and drove, besides an alternator, a heavy and wasteful double (and in one case treble) set of countershafts provided with a large number of belts, fitted to an arrangement of fast and loose pulleys for convenience of testing all sorts and conditions of dynamos. I mention this as showing that the momentum in each case was very considerable.

In order to make the test as onerous as possible, the pulleys used were such that one engine had to run at 130 revolutions, while the other ran at 90 revolutions, when the alternators were at their normal speed of 650 revolutions per minute.

(1) The alternators were run up to full speed, and each excited to give 2,000 volts. When in phase they were switched parallel without any external load, and without any impedance coils or resistance between them. They run parallel perfectly.

(2) A considerable inductionless load was then put on, varied, and taken off. They ran equally well under all circumstances.

(3) They were uncoupled, and then, the load being connected to the mains, they were suddenly and simultaneously switched parallel and on to the mains with perfect success.

(4) One alternator was excited to give 1,000 volts, the other giving 2,000 volts. They were then switched parallel, and went into step perfectly, giving a terminal P.D. of about 1,500 volts. No impedance or resistance was used in this or in any other case. A load was then put on without affecting their behaviour.

(5) With one machine at 1,000 volts, and the other at 2,000 volts, they were switched parallel *when out of phase*, and instantly went into step. A large current appeared to pass between them for a fraction of a second, but not nearly long enough to enable it to be measured, or to do any harm.

(6) They were then left running parallel while one was disconnected from the engine, by its belt being shifted from the fast to the loose pulley. It continued to run as a motor synchronously. A load of lamps was at the same time on the circuit.

(7) The two machines were then uncoupled and excited up to 2,000 volts. They were then switched parallel when out of phase and without any external load, and went into step instantly.

(8) Whilst running as in (7) steam was suddenly and entirely shut off one engine. The alternators kept in step perfectly, one acting as a motor and driving the large engine and all the heavy counter-shafting and belts. It was impossible to tell, except by the top of the belt becoming tight instead of the bottom, which machine was the motor.

To find the power exerted by the alternator acting as a motor (in 8), a direct-current motor was put in its place, and the power required to drive the engine and shafting was found to be 20 h.p.

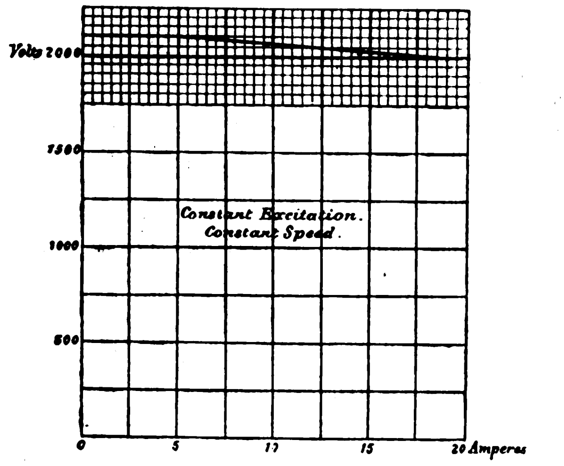

Fig. 1.—Characteristic.

It may be pointed out that these tests were made under the most exacting and onerous conditions that could possibly be imposed, and particularly I would point out that on account of the very great momentum of the revolving masses, nothing but the strongest and most instantaneous motor action could have kept the machines in phase. There never was a single case when they got out of step, even momentarily, or when subjected to sudden and violent variations of load. When it is considered that, in order to secure this result, it was imperative that the control of all that mass should be exerted in a fraction of $\frac{1}{100}$ of a second (the periodicity being 100), it will be recognised that there was no time to be lost, and that the use of any self-induction or resistance, or of anything else that could in any way choke, retard, check, or interfere with the strength and instantaneity of the action was above all things to be avoided.

I should mention that the machines apparently synchronised equally well at speeds varying very considerably.

As to the self-induction of the machine itself, that is quite negligible. Its characteristic, Fig. 1, is nearly straight, about half the drop in the curve being due to resistance, and half to self-induction.

Here was a machine generally allowed to be good when working singly, but possessing all the qualities that have been stated as unfitting it for parallel work, tested under all the conditions that are recognised as most trying, even for those types of alternators which are universally, and I believe erroneously, regarded as best suited for parallel work, and behaving throughout in a manner that simply left nothing to be desired, and carrying, unimpaired, into parallel work those features which it possesses when run singly.

I trust that I have now said enough to justify the views I have expressed.

A few particulars of this machine may be of interest. It now takes 500 watts to excite it at full load, and rather less than 400 watts on open circuit with full E.M.F. The efficiency when working with a light load is very high. The power required to run at full speed, with full E.M.F., but no external load, is 3 h.p., of which 1·5 h.p. is ordinary mechanical loss in the bearings, etc., and 1·5 h.p. is electrical waste in the armature conductors and supports. This is from a most careful test, and shows that, so far as economy is concerned, with light loads the machine does not leave much to be desired. This is really of very great importance, for the expense connected with central station working during the long hours of daylight may be a serious item.

Alternate-Current Motors.

The bearing of the foregoing on the great and vital question of the construction of alternate-current motors is obvious. Much work has been done of late on this subject, and no doubt considerable success has been met with, but the use of alternators as simple synchronising motors has not appeared to attract much attention, probably because it is not known what excellent results may be obtained in this direction, and partly because of their inability to start from rest.

The experiments just described, and others that I have carried out, showed what perfect self-governors such motors are. Not only do they maintain synchronism, but they possess an inherent economy which is most valuable. Just enough current passes through them to keep them in step, and to do the work imposed on them. They become generators, and do work on the circuit, if from any cause there is a tendency for them to run faster than the generator.

I have devised a very simple means of starting such motors, which at a small expense removes the only drawback to their employment. The exciter, which is geared directly in some way with the alternator, is used in conjunction with a small accumulator, as a direct-current motor to start the alternator. When synchronism is attained, the latter is simply switched into circuit. It will be obvious that a small battery capable of a heavy discharge for a minute or two is all that is required. This is recharged by the exciter. I need not go into the details of the arrangements. This is perfectly practical. I should have no hesitation in running these alternators in regular work as motors, and should expect to find their "commercial efficiency" very nearly or quite 90 per cent.—about the same efficiency, whatever it is, that they possess as generators. For instance, the machines alluded to will work as motors at a useful output of 50 h.p. with this efficiency.

And here is another advantage in getting alternators economical when on open circuit. By doing so it becomes possible to use the very small exciter as a direct-current motor to get them up to the synchronising speed.

In many situations a synchronising A. C. motor will fulfil all requirements, and will do so with fewer drawbacks than any other kind of electric motor whatever. It will be a better regulator, more economical, less troublesome to look after, much safer to handle, and —what is of very great importance in connection with the transmission of large powers to a distance—the difficulty of dealing with high pressures, which is so serious with direct-current motors, is very easily overcome, for not only will alternators stand a higher tension in themselves, but, if necessary, transformers may be used to reduce the pressure between mains and motor.

Periodicity.

Some confusion is caused by the various ways in which rates of alternation are expressed, it being often quite uncertain whether periods or half-periods are referred to when "alternations" or "reversals" are spoken of. This confusion should be avoided by using the term "period," which has, I think, always been taken as expressing the complete cycle, or the changes undergone by a simple rectangle or elementary armature rotated from zero through a complete revolution in a simple magnetic field. To save confusion I would suggest a sign be used, unless a better one be forthcoming, and that we agree to speak of periods, instead of alternations or reversals, and of periodicity, instead of frequency or rates of alternation or of reversal.* Prof. Silvanus Thompson informs me that formerly a somewhat similar difficulty arose in regard to sound, and that confusion was avoided in the science of acoustics by giving the word "vibration" the definite meaning of the double motion which it now possesses, the French tuning-forks being stamped with the letters "V.D." (*vibration double*) after the number.

The subject of periodicity is becoming a very important one, for both commercial and scientific reasons. It urgently demands settlement in the interests of the whole industry. The very wide differences found in scientific opinion on this matter, and in the practice of the various manufacturers, must lead, and are indeed now leading, to much confusion and inconvenience. As things stand at present, great uncertainty exists not only as to what rate is the best, but whether transformers, arc lamps, or other apparatus made by one maker, for a given E.M.F. or purpose, can be used on a circuit, fed from an alternator constructed by another maker. It might be suggested that some joint action should be taken by manufacturers and others concerned, in the direction of securing uniformity; but there are arguments against such a course, the principal one being that probably each maker believes he has good reasons for his own practice.

I venture to think there is no right or wrong periodicity. What may be best for one set of conditions, or with one type of apparatus may not be best for another. Or, perhaps, it would be more correct

* This sign may be written something like, but rather larger than the algebraic sign for "difference."

Digitized by Google

to say that there is a right periodicity, and that there are right and wrong apparatus; but this is rather a delicate subject.

The relative advantages of high or low periodicity must be considered as bearing on the five main divisions of apparatus used. Taking these in their natural order they are:

1. Prime Motors.
2. Alternators.
3. Conductors.
4. Transformers.
5. Lamps, etc.

Each of these divisions contains matter in relation to periodicity which in the near future will probably form the subject of many papers as the various subjects become better understood. I am not able to do more than touch briefly on each, in the hope that my remarks may lead to the expression of the views of others, and to some approach to uniformity.

1. *Prime Motors.*—At present questions affecting prime moters do not usually bear directly on the subject of periodicity. The only exception is the Parsons steam turbine, with which there seems to be no great difficulty in using a simple two-pole machine, thus making the number of revolutions and of periods the same. There may be found some want of flexibility as regards changes of size or output with such turbines, as, from the nature of the case, speed can only be varied by very large amounts. Thus, for instance, if 100 periods are required, there is no choice except between a two-pole machine at 6,000 revolutions per minute and a four-pole machine at 3,000 revolutions. This is, of course, on the assumption that the alternator is driven direct. If indirect driving is resorted to, the difficulty is much reduced. It is unlikely, however, that the bearings of a steam turbine would work satisfactorily except with direct driving.

2. *Alternators.*—It is not allowable to doubt that the divergencies in periodicity found in practice are to a great extent the result of development and survival of what has been found to give the best results in each case; but from an examination of the machines in use it is very difficult to trace any common line on which action may be supposed to have taken place. It is true that the general tendency has been towards a reduction of the periodicity, but the causes which are responsible for that tendency are very obscure. I have seen large and small machines, made at the same time by one maker, in which the number of coils was the same, although one had to run at about 2,000 revolutions a minute, and the other at less than half that rate of speed. At least one of these was wrong. For the purpose for which these machines were made the very high periodicity was almost unobjectionable in the small machine, but in the large ones it led to disaster.

It is a common mistake to suppose that high speed of driving, or high peripheral velocity, are necessarily connected with high periodicity and with large output. Of course any given machine, if run at a higher rate of speed than its normal one, must have a proportionately higher periodicity, but will not necessarily be capable of a greater output. It is quite possible to design a high-speed machine to give a low periodicity, and *vice versâ*. Perhaps the impression has arisen because with most alternators it is not possible or desirable to place the successive poles very close together on account of the magnetic leakage.

For machines with iron in the armatures, it might be expected that the magnetic and electric losses, as well as the very considerable self-induction and consequent variations in the effective potential differences with changes of load, would lead to the reduction of the periodicity; but experience does not seem to have always led to this result. The lowest periodicity (42 with the Zipernowski machine) and the highest (132 with the Westinghouse machine) are both found in alternators having iron cores. What is the reason of this great diversity? The machines have many points of resemblance, and yet one is run at more than three times the periodicity of the other. Not having seen the American machine, I can offer no opinion based on personal observation; but of the Austrian alternator I can say that, in my opinion, it would not be advisable to increase the rate.

In a communication from Messrs. Ganz and Co., published a few days ago,* Mr. Zipernowski says that the low periodicity used was chosen on principle to enable them to couple their dynamos parallel. He very cogently adds, in justification of this: "At present no practical electrician will hesitate to acknowledge the coupling of dynamos in parallel circuit to be a vital question of any parallel system of central station distribution."

This bears out very completely my contention that the periodicity is governed in most cases by some special feature of the type of apparatus. Zipernowski has had to go down to 42 periods to get his iron-cored alternators to synchronise, and for no other reason; for his statement is that synchronous action was "not a secondary result, but just the end we were aiming at," and he acknowledges that there are disadvantages connected with this low rate in other parts of the system.

But Westinghouse with 133 periods, and Lowrie-Parker with 80—both having iron cores—can run parallel: the former with not less than half-load; the latter, as we now know, with any load; and I think I could run parallel without iron and at any load and periodicity, so that Mr. Zipernowski's only reason fails to justify his action, except as regards his own particular apparatus.

Prof. Forbes recently stated that the exhaustive tests made in America with the Westinghouse apparatus had shown that there was no reason for reducing the rate of alternation, which is the highest now in use. This is very important, and it is to be hoped that some account will be given of the nature of the trials and of the results obtained. Mr. Ferranti, who at one time used very high rates, has for some time been using 80 periods at the Grosvenor Gallery, and has fixed 68 periods for the Deptford machines. I shall not be surprised to see him increase this before long.

In my own machine the periodicity is 100, which, I believe, is on the whole the best rate; but if it be required to do so for any special purpose, there would not be much difficulty in changing it. The pole faces can be altered in number and in size by merely altering the pattern. The field-winding, being in a single coil, would be equally simple and equally efficient for any periodicity. Even with a large number of poles placed close together, as would be required for a high rate, magnetic leakage would not increase. The size of the machine would not be sensibly affected. The armature would certainly be rather more costly for a high rate, as a greater number of coils would be required; but the efficiency, output, and regulating qualities would remain practically the same. Regarding this machine, I think I may say that periodicity is not a question of the first importance. As far as I am concerned, it is other divisions of the distributing apparatus that determine the rate at which it is desirable to work.

The bearing of the form and arrangement of any alternator on the best periodicity for that alternator is a very close one. The question cannot be settled on general principles.

I have referred elsewhere more fully to the conditions as they affect regulation under varying loads, parallel working, and other points in connection with alternators; and, as an appendix (see p. 20), I have quoted some observations made recently at the Institution of Civil Engineers during the discussion on Mr. Kapp's paper on "Alternate-Current Machinery," and not yet published.

I now pass on to the next division of the subject.

3. *Conductors.*—The choice of a suitable periodicity depends also to some extent upon the conditions as they affect the conductors.

The effect of rapid alternations in virtually increasing the resistance of conductors has been brought before us in Sir William Thomson's presidential address, and it becomes necessary to recognise clearly what practical limitations are imposed by this effect.

My attention was drawn to this matter two or three years ago, when I was called upon to examine and report upon an installation of about 1,000 100-volt lamps supplied directly by an alternator working at about 150 periods. It was found that there was a very serious drop of potential in the conductors, and, in consequence of this, the lamps could not be maintained at full power. On examining the circuit I found the cables were of ample size, and that the loss could not be explained in the usual way. As a result, I came to the conclusion that it was to be accounted for only by some kind of inductional action, due to the alternating current, and I advised that a direct-current dynamo should be put down in place of the alternator. This was done, and with a perfectly satisfactory result. The lamps were for the first time run at their proper power, and no further trouble was experienced.

At that time I was, like most other electricians, a disbeliever in alternating currents, which I vaguely regarded as essentially unsatisfactory. I think there was a more substantial basis for this opinion than is now generally admitted. Alternating currents as then most often used were not satisfactory; and if great care is not taken at the present time, some of the old difficulties will be encountered, with the result of unnecessarily discrediting the transformer system of distribution.

(*To be continued*).

ON LIGHTNING, LIGHTNING-CONDUCTORS, AND LIGHTNING-PROTECTORS.

The following is an abstract of the discussion which took place upon the reading of Dr. Lodge's paper on the above subject at the Institution of Electrical Engineers.

In opening the discussion, **Mr. Preece** said he did not wish to appear as antagonist of Dr. Lodge, but as a defender of the Lightning Rod Conference and the "older electricians," and as an advocate of "experience" as distinguished from "theory." Those of the older school were guided by and had a great veneration for facts, whereas the deductions of theory were based on assumptions guided by mathematics, and were not always true. Referring to case *a* (steady strain), he contended that no difference of opinion existed, and that this was the case taken up by the conference. With regard to the relative merits of iron and copper for conductors, the conference considered the question judicially and recommended copper, chiefly because of its greater durability. He himself always advocated iron, and considered a No. 4 galvanised wire amply sufficient for ordinary conductors. As a proof that self-induction was not ignored by the conference, a passage from the report was quoted which states that the suddenness of lightning discharges affects the conductivity. Coming to case *b* (impulsive rush), great difference of opinion exists. Though he had no doubt about the reality of the phenomena shown in Dr. Lodge's experiments by the aid of Wimshurst's machine, yet he contended that the deductions drawn from them were not necessarily true, that Leyden jar discharges were not comparable with lightning flashes, and that the tin plates used to represent clouds differed greatly in conductivity from clouds, which, on the authority of Dr. Lodge, are very imperfect conductors. He considered that the conditions of the experiments more nearly imitated a broken conductor, and mentioned that many similar experiments were made fifty years ago by Mr. Andrew Cross. As regards the oscillatory character of discharges, all agreed that Dr. Lodge had shown that Leyden jar discharges could be made oscillatory by introducing self-induction, but he (Mr. Preece) thought there was no conclusive evidence that lightning flashes were so. On the contrary, telegraphic records of flashes made by Bain's chemical system, Thomson's

* The *Electrician*, May 10, 1889, p. 16.

Digitized by Google

recorder, and Wheatstone's receiver, show no signs of oscillation. A recent case was described in which a Wheatstone receiver was kept running during a thunderstorm in Anglesea on Sunday, the 5th inst., and the resulting tape was exhibited. Further evidence of the unidirectional character of the current was said to be afforded by the signs of electrolysis exhibited by some conductors, which had been broken by flashes. He had also examined wires fused by lightning in which the fusion appeared to have started in the interior, whereas, according to Dr. Lodge, the current is confined to the outer layers. This, the speaker submitted, tended to disprove the theoretical deductions, and thought that the fact of telegraphic instruments always being fused inside the coils pointed in the same direction. Referring to lightning-protectors in general use, experience proved that instead of such things being of the "most utterly imperfect kind," they were of immense service, for in the Navy no accident had been recorded since 1872, and in the Post Office telegraphs not a single pole out of half a million had been damaged. In 1872, before the instruments were fitted with protectors, 19 per cent. of the instruments in use were damaged; but now the percentage is reduced to 1·3, and this he believes due to the non-protected instruments still in use. Several conclusions of the Lightning-Rod Conference had been severely criticised by Dr. Lodge in section 39 of his paper, particularly those relating to the protection afforded by well-earthed conductors, and in reply to this criticism Mr. Preece said he was quite prepared to clasp a good conductor during a storm, or even to sit on a barrel of gunpowder through which the conductor passed.

Mr. C. W. Vincent, speaking of oscillations, said that he assisted Faraday in making experiments on the discharge of a large Leyden battery through various materials, but no signs of oscillation were noticed, although cases of intermittent discharge were frequently detected.

Mr. Farquharson described a singular case of damage to H.M.S. "Coquette," in which part of the conductor passing from the mast to the copper sheathing of the vessel was torn away from the beam to which it had been attached. The only defect found in the conductor was a bad joint near the top, and he could never understand how this defect could cause the observed effect.

Mr. J. Wimshurst considered that there was nothing very new in the impulsive rush, for he had been acquainted with it for some years. As regards the protection afforded by points against an impulsive rush, this depended greatly on whether the cloud was positively or negatively electrified. To show this, a dome and point were placed on the lower of two insulated metal plates, and Leyden jars discharged into the upper. When the top plate was + the point was struck equally with the dome when both were at the same height, but when the electrification was reserved the point afforded great protection. This difference is of consequence in Dr. Lodge's "bye-pass" experiments, and he (Mr. Wimshurst) had found that putting on the bye-pass reversed the direction of the spark across the air space.

Prof. W. G. Adams said that, as chairman of the Lightning-Rod Conference, he thought the work done by that body had been misrepresented and unfairly criticised, for its objects were to examine and report on what was then known on the subject, and to condense existing knowledge so as to form a scientific basis for future practice, and these objects he considered were well carried out. He acknowledged that Leyden jar discharges produced remarkable effects then unthought of, but considered the statement that lightning flashes were strictly analogous unproved. As illustrating the truth of the older views, the case of Brussels Town Hall was cited. This building, although elaborately protected on M. Melsen's system, has been recently struck, thus proving that the adverse opinion expressed by the conference on the system adopted to be well founded. Another case in which the views of the conference received confirmation, occurred at the South Foreland Lighthouse, in 1885. The flash struck the lantern, leaped to the electric lamp, passed through a long cable to the magneto machines, and thence, by way of the engine-room conductor, to a well 280ft. deep, into which the conductor was earthed. The lighthouse conductor, where seen, was in perfect order, but the earth plate was found buried about 18in. below a gravel path, resting on dry chalk. A man standing within a foot of the spark as it passed to the electric lamp felt no shock.

Prof. Fitzgerald, on rising, said he had said nearly all he had to say at Bath, but he wished to point out that the data now brought forward by Mr. Preece did not prove the non-existence of oscillations, for in all discharges, whether oscillatory or not, there is a definite flow in one direction, which would produce the telegraphic records. Referring to Dr. Lodge's paper he said the weak point was the assumption that clouds behaved like good conductors, for it was well known that in horizontal directions they were very bad conductors. Of course it was possible that a shower might make them good conductors vertically, but this was a point on which no reliable data existed. Before Dr. Lodge's experiments, the speaker said it would have been very difficult to account for the setting fire to the Hôtel de Ville at Brussels by sparks from an isolated bar of metal, and although the Lightning-Rod Conference had done much good work, there were still many obscure points requiring experimental examination.

At this stage of the discussion, **Dr. Lodge** (who was unable to attend the next meeting) briefly replied to some of the questions raised. With regard to experience *v.* theory, he considered that theory, guided by experiment, more likely to make progress than unguided experience. Owing to lack of theory, Edin called into existence "etheric force" to explain phenomena of a character similar to those produced by electric surgings, and Mr. Mascart had observed similar phenomena, but had not described them because he could not understand them. Mr. Preece had said that no difference existed between them as regards case *a*, but this Dr. Lodge thought was not correct, for he maintained that surgings occur in case *a* as well as in case *b*; and he could not admit that when there was no oscillation, there was no self-induction, for self-induction existed in every circuit. Judging from Preece and Sivewright's telegraphy, he concluded that lightning-protectors frequently failed, and to be really efficient, no single failure should occur. Referring to Mr. Wimshurst's experiment, he said that he had not noticed any difference between the different protective effect of points with charges of opposite sign, for he never troubled himself about the matter of sign. In conclusion, Dr. Lodge expressed his opinion that the Lightning-Rod Conference did much good work, and regretted that he should have seemed antagonistic towards it.

The discussion was then adjourned to May 16, when Mr. Wimshurst proposed to show his direction "analyser" in action as well as other experiments bearing on the subject under discussion.

Mr. Wimshurst, on resuming the discussion on 16th inst., reperformed his experiments on the difference in the protective power of points when the clouds are positive or negative, and said that in the latter case the point might be 2¼ to 2½ times as far away from the cloud as a dome, and still protect. The reversal of the direction ot the "*b* spark" by putting on a "bye-pass" was also shown, together with experiments indicating that imperfect earth greatly increases the tendency to side flash, and that this tendency is further increased by augmenting the size of the body receiving the flash, and by connecting it to earth. In view of these facts, the experimenter considered that the conclusions of Dr. Lodge respecting the small importance of good earth, and the propriety of connecting all pieces of metal together, and to the earth, needed reconsideration. Side flashes were also taken by Leyden jars, and in some cases they were found uncharged when tested, whilst in others the charge remained. An experiment analogous to the sparking seen on the gilding of the walls during Dr. Lodge's experiments was next shown, in which sparks passed between separate pieces of foil, forming a spangled outer coating of a Leyden jar, when an insulated body within the jar was connected to an influence machine at work.

Prof. Hughes said he did not agree with Dr. Lodge's statement that the "older electricians" never contemplated case *b*, for Sir W. Snow Harris had recognised the difference, and from experiments made by Prof. Guillemin, M. Bertsch, and himself, in an investigation on lightning-protectors (see "Annales Telegraphique," 1865, and *Electrician*, July 13, 1888), it was concluded that Leyden jar discharges differed from ordinary lightning, for it was well known that protectors did protect instruments, whereas in their experiments with large jars nothing protected them. He also considered it unfair of Dr. Lodge to take all the credit of having recognised the distinction between cases *a* and *b*, and the influence of self-induction, to himself, altogether ignoring his predecessors in the field, for Prof. Guillemin showed that a sheet of tinfoil might protect an iron wire, whereas the same foil rolled up like a wire failed to protect. As regards iron *v.* copper, his (Prof. Hughes') experiments prove that for rapidly varying voltaic currents copper is decidedly superior, and the preference now given to copper for telegraphic and telephonic work points to the same conclusion. It had also been shown that iron wire was circularly magnetised by discharging a Leyden jar through it, and the production of this effect would, he considered, retard the discharge.

Mr. G. J. Symons thought Dr. Lodge did not realise the alarming nature of his own remarks in reference to the rules of the Lightning-Rod Conference. As a member of that body, he was anxious to improve the rules wherever possible, but considered it injudicious to discard well tried and safe rules until something better had been devised and tested by experience. As regards points *v.* knobs, the subject had been thrashed out 120 years ago. The Lightning-Rod Conference had recognised the importance of hot-air currents, for they recommended that house conductors should be fixed to the kitchen chimneys. The dimensions of conductors was next referred to, and from the fact of large ones having been fused, the speaker thought Mr. Preece should not recommend small wire. He also stated that although the existence of a "protected area" around a conductor was disputed, yet much evidence pointed in that direction.

Colonel Armstrong, R.E., speaking of the protection of magazines, said he believed the War Office were the only body who had regular and systematic earth-resistance tests made on their conductors. From his experience in the matter he could say that no accident had ever happened to a magazine whose conductors made good earth, as shown by the regular tests, whereas several had occurred in cases where the earth was bad (say 200 ohms). In one case the conductor was fused below the point at which the main flash left the conductor, and this he believed due to want of continuity at the lower place. In another case cartridges packed in a sealed metal case were exploded by a lightning flash, thus showing that currents were not confined entirely to the outer layers as Dr. Lodge supposes.

Mr. A. J. S. Adams considered wires carrying varying currents to be under stress, and that such stress was relieved by radiation from the wire. The amount of this so-called radiation he takes to be a measure of the opposition offered to the passage of the current, and says that copper radiates about 25 per cent. less than iron or brass.

Mr. Spagnoletti said telegraph wires were very seldom fused, although instruments were frequently damaged, and, as an instance of such wires conveying large lightning currents, cited a case in which a lineman was killed by touching a wire which was struck by lightning at a point 50 miles away. He also asked whether lightning flashes had been proved to be oscillatory?

Mr. S. Evershed described some observations he made in 1877, which tend to show that the "*b* spark" does occur in nature. A thunderstorm was in progress about five miles from his place of observation, where he had a goldleaf electroscope and a quadrant electrometer connected to an insulated plate about 6ft. high. In the intervals between the flashes the leaves remained open about ⅛in.; but instantaneously with each flash they opened to three times that amount. The spot of light from his electrometer disappeared with such rapidity that he could never say in which direction it moved.

Digitized by Google

These facts also show that Nature is not always "slow and solemn," as Mr. Preece would have us suppose; and the peculiar effects exhibited at Antwerp railway station prove that lightning does not always behave in accordance with the views of the Lightning-Rod Conference. Referring to Mr. Preece's supposed proofs from telegraphic records that flashes are not oscillatory, Mr. Evershed pointed out that such records would be produced, even if oscillations were present, for a greater quantity of electricity passes in one direction than in the other.

The **President**, Sir W. Thomson, in closing the discussion, thought Dr. Lodge's paper a most interesting and valuable one, and the Institution was greatly indebted to its author for bringing the matter so prominently forward. All admit that the importance of self-induction was not sufficiently recognised previously. He could not say whether Franklin knew of its existence, but Sir W. Snow-Harris did, and many views held by the latter, which until recently were condemned, have now been proved correct. Referring to section 56 in the paper, he thought Dr. Lodge did not mean what was there stated as to the shape of section of the conductor, for it was quite certain that flat ribbon had much less self-induction than round rod. As regards gas and water-pipes as earth, Sir William considered that they made a good earth, and he did not see much danger in connecting pieces of metal with the lightning-conductor in cases where other earth could be obtained. In view of Colonel Armstrong's statement about cartridges being exploded when completely enclosed in metal casings, he thought it important to try if iron cases afforded more protection than brass or copper ones, for it was probable that the magnetisation of the iron by the currents would produce additional screening. Faraday's electric cage experiment should also be repeated, using the more sensitive apparatus since devised to search for any internal effect. In conclusion, the President said the report of the Lighting-Rod Conference is a very important work, and though some flaws may exist, yet, on the whole, experience gives very strong reasons for believing that the rules are good.

PHYSICAL SOCIETY.—May 11.

Prof. Reinold, President, in the Chair.

Mr. A. Clegg, Prof. V. B. Lewis, and Mr. W. Robinson were elected members of the society.

The following communications were read:

"On an Electrostatic Field produced by varying Magnetic Induction," by Dr. O. J. Lodge, F.R.S. This paper describes a research made with the object of finding some connection between static electricity and magnetism. Several methods of attacking the problem, such as rotating or varying the strength of magnets in the neighbourhood of delicately suspended charged bodies, are indicated, and the one selected was based on an idea of Mr. A. P. Chattock, who conceived that a charged body in the vicinity of a closed magnetic circuit would be affected by varying the magnetic induction. From the theory of the effect it is shown that the magnitude of the quantity sought is exceedingly small, for the expression involves the inverse square of the velocity of light. The E.M.F. induced in any closed curve round the magnetic circuit or solenoid, by varying the induction I, is given by $e = \frac{dI}{dt}$ (1). If an E.M.F., e, act on a charge, Q, at distance, r, from the axis of the solenoid, the work done in one revolution will be e Q, and $e\,Q = F\,2\pi r$ (2) where F is the mechanical force. Now if the E.M.F. in (1) is the same as that in (2) the impulse given to the charged body by destroying the induction will be $\phi = \int F\,dt = \frac{I\,Q}{2\pi r}$ (3). Since $I = \frac{4\pi n C A \mu}{l} = \mu$ C times a length, and $Q = sV$ = K V times a length, $\therefore \phi = \frac{K \mu C V A}{2\pi r}(\text{length})^2$ and $K\mu = \frac{1}{\text{“}v\text{”}^2}$

$\therefore \phi \propto \frac{1}{\text{“}v\text{”}^2}$

The magnetic circuit actually used was a wire Gramme ring of trapezoidal section wound with copper over only a part of its periphery. The indicating apparatus was a suspended needle, consisting of two oppositely charged bodies carried on a small shellac arm, to which a mirror or pointer was attached, and was suspended vertically in the plane of the ring. Great difficulty was experienced from the Foucault currents when metallic films were used for the needle, and the magnetic properties of other semi-conductors tried further complicated the matter. Eventually the charged bodies were made of paper in the form of cylinders ¼in. diameter and ¾in long. Considerable trouble was caused by the electrostatic action between the needle and exciting coils, and various methods of screening were tried and abandoned, and subsequently the wire was replaced by a single spiral of copper ribbon, the outer turn of which was put to earth. Observation was rendered difficult owing to the wandering of the zero when the needle was charged, but this was minimised by suitably shaping the contour of the needle's surroundings. Heat also created considerable disturbance, and the convection currents were cut off by a series of concentric cylinders of tinplate. The method of observation was to charge the two insulated parts of the needle, and then reverse the magnetising current in synchronism with the period of the needle, noting whether the amplitude of any residual swing could be increased or diminished according as the impulse assisted or opposed the motion. In this way slight indications have been observed, and the effects reverse when the charges of the cylinders are reversed. In explaining the theory of the experiment, the author made use of a simple transformer, consisting of an ordinary hank of iron wire wound over with insulated copper, and provided with several secondary coils, and by it he demonstrated that the primary current increases on closing the secondary, due, as was shown, to the decrease of self-induction of the primary caused thereby.

Prof. Fitzgerald, in answer to a question from Dr. Lodge as to the influence of screens, said he had not fully considered the matter in this particular case, and as the general effect of screens depended on the square of v, the subject required careful treatment. As a means of checking the results obtained by Dr. Lodge, he suggested calculating the impulse, and seeing whether its magnitude approximately corresponds with that observed. Commenting on an idea for carrying out a similar experiment, attributed to him in the paper in which a charged gold leaf is placed between the poles of a magnet, Prof. Fitzgerald said he had been misunderstood, for he had conceived a disc parallel to the faces of the magnets which, when excited, should cause the disc to turn in its own plane. Referring to the equations for mechanical force given in Maxwell, section 619, he pointed out that the coefficient of e in the equation $X = ev - bw - e\frac{d\Psi}{dx} - m\frac{d\Omega}{dx}$ ought to be P, where $P = cy - bz - \frac{dF}{dt} - \frac{d\Psi}{dx}$, and considered it very important that the existence of the term $e\frac{dF}{dt}$ should be tested experimentally.

Prof. S. P. Thompson mentioned some experiments on which he was engaged, by which he hoped to show electric displacement in continuous dielectric circuits, such as a hank of guttapercha. Up to the present, the experiments had not been successful, owing to his inability to place the two Gramme ring coils used into such relative positions as to give silence in the telephone connected with the coil used as secondary, when currents were sent through the primary.

Prof. Ayrton suggested that Dr. Thompson's difficulty may arise from the fact that such rings do produce considerable external field, even when carefully wound.

Prof. Fitzgerald requested Dr. Thompson to investigate the effects of displacements currents and of changing vector potential, and pointed out that in a single medium the former can produce no magnetic effect. As regards fields containing different media, he said the calculations would be complicated by the spurious charges on the separating surfaces.

Dr. Lodge, in reply, said he had calculated the momentum to be expected in one arrangement of his experiment in which a suspended aluminium cylinder surrounds one limb of a rectangular magnetic circuit which formed the core of an induction coil One end of the secondary was put to the core, and the other to the cylinder, thus forming a condenser. The result came out about 10^{-6}dyne second, but he could not say whether such a small quantity was observable.

"On the Concentration of Electric Radiation by Lenses, by Dr. O. J. Lodge, D.Sc., F.R.S., and James L. Howard D.Sc.

The authors' first attempts at concentration were made with mirrors on a comparatively small scale, and owing to the difficulties experienced, it was considered advisable to try lenses. Two large cylindrical ones of plans hyperbolic section were cast of mineral pitch in zinc moulds, the plane faces being nearly a metre square, and the thickness at vertex 21cm., and each lens weighed about 3cwt. The eccentricity of the hyperbola was made 1·7 to approximate to the index of refraction of the substance. The lenses were mounted about 6ft. apart, with their plane faces parallel and towards each other on a table in the college corridor, and an oscillator was placed about the principal focal line of one of them at a distance of 51cm. from the vertex. The field was explored by a linear receiver made out of two pieces of copper wire mounted in line on a piece of wood, and an air-gap between their inner ends was adjustable by a screw. When the oscillator worked satisfactorily the receiver would respond to about 120cm.; and with the lenses the distance was 450. The receiver responded anywhere between the lenses and within the wedge between the second lens and its focal line, the boundaries being clearly defined, but no special concentration was noticed about the focus. Interference experiments were carried out by placing a sheet of metal against the flat face of the second lens and determining the positions of minimum intensity between the lenses. The distance between these points was 50·5cm., corresponding with a wave length of 101cm. whereas the calculated wave length of the oscillator was 100c.m.

Prof. Fitzgerald congratulated the authors on their success, and also pointed out that although large oscillators give good results at distances within a few wave lengths, yet at greater distances small ones were decidedly superior, owing to the energy of radiation varying as the fourth power of the rapidity. He had recently made experiments on electric radiations analogous to Newton's rings, and had successfully observed the central dark spot and the first dark band. Referring to Dr. Lodge's experiments, he enquired whether any traces of diffraction were observed near the boundary of the bundle of rays between the lenses. Speaking of polarisation experiments, Prof. Fitzgerald said waves reflected from films of water exhibited no polarisation, whereas those reflected from non-conductors were completely polarised.

In reply, **Dr. Lodge** said no diffraction effects had been observed, but in the interference experiments to determine wave length, the positions of minimum effect were very decided.

The **President**, in proposing that the thanks of the meeting be given to the authors of the papers, congratulated the society on the presence of both Dr. Lodge and Prof. Fitzgerald on the present occasion, when subjects with which they were so well acquainted were brought before the meeting.

BOARD OF TRADE ENQUIRY.

SATURDAY, APRIL 27.

Major Marindin, C.M.G., R.E., on behalf of the Board of Trade, resumed the enquiry at the Westminster Town Hall, for the purpose of hearing, on the part of a number of electric lighting corporations, their provisional orders to erect and maintain electric lines and works, and to supply electricity within certain areas in the metropolis and elsewhere, and the objections raised thereto by other companies and corporate bodies.

Mr. Wallace, who represented the Kensington and Knightsbridge Electricity Company, replied to the various objections raised by the Vestries of St. Mary Abbott's, St. Margaret's, and St. John's, most of which he said his company were willing to meet.

Mr. Shiress Will replied for the House-to-House Company, but raised no question of public importance.

Mr. Wallis, who represented the Westminster Electric Supply Corporation, said that his company had chosen sites, and had already used an amount of preliminary capital in erecting a station for the supply of 5,000 lights. How had the London Company gone to work? They started at the Grosvenor Gallery, and laid down an installation which it was admitted they had had to abandon. Moreover, the capital that they had used to commence a system of overhead wires was wasted. They did not in the first instance apply for a provisional order, but attempted to appropriate certain portions of London in an illegitimate manner. In other words, they spent their money, erected a station, and laid down their plant on no security whatever, instead of waiting to see whether or not they would get their provisional order. He (the speaker) ventured to say such a company as the London ought not to be trusted with the lighting of any portion of London, and he was convinced that the Board of Trade would share that conviction. Besides, Sir William Thomson said that their system was a gigantic experiment. The local authority of St. George's, Hanover-square, were satisfied with the Westminster Company. As to St. Margaret's and St. John's parishes, Westminster, they refused all companies alike. His company abandoned the Strand, St. Martin's, and all places where their interests collided with those of the Metropolitan Company and the Electric Power Storage Company.

Mr. Moulton, Q.C., then began his address on behalf of the Chelsea Electricity Supply and the E.P.S. Companies, and said that the question of satisfying the Board of Board of Trade that sufficient capital was appropriated for the purposes of lighting ought not to be matter for the enquiry, but at the moment the Board of Trade called such evidence, both his companies were in a position to amply satisfy the body. He might even say for the E.P.S. Company that they had already satisfied the Board of Trade as to their financial strength for the duties they proposed to undertake. With regard to what had been said about the intention of the E.P.S. Company to obtain an order for themselves, and to transfer it to others for a profit, it would be open to the Board of Trade to keep the company as the undertakers.

MONDAY, APRIL 29.

Mr. Moulton, continuing his address, said that there was not the slightest intention on the part of the E.P.S. Company to transfer or sell its order at a profit. The real thing for the Board of Trade to do was to find out that there was capital which would be appropriated to the working out of the order, and that the persons who were going to work it were of such standing as to be entrusted with it. In referring to the question of system, and how the transformer system affected the need of further provisions, or justified a relaxation of the model order, he submitted that so far from justifying any departure from the model order, it only emphasised the importance of the obligations under it. The transformer system differed from the direct supply in this, that the natural inducements to do its work thoroughly, and make electric lighting a thing used from house to house, were absent. The London Company, it seemed to him, had seized on this great feature of the transformer system that it would enable them to hold the City against all competitors. Under the guise of inviting competition, he thought that company were asking the Board of Trade to sanction an attempt which would leave London as much at the mercy of a large corporation as it had hitherto been in the case of gas and water companies. For motive power the direct supply was the only form of supply that could be used. It had been suggested that somebody had solved the difficulty about the alternating motor, but to his mind it was all in the air. The transformer system proposed to bring electricity into every house under circumstances which would be dangerous to life and property. He quite admitted the value of the safeguards against possible danger, but it was not quite easy to see how, on some occasion, imprudence or carelessness would be avoided. He could not see that the transformer system was a cheap one, and no figures had been quoted to prove it. Its chief advantage lay in the fact that it was more suitable for straggling districts. Nothing had yet contradicted his argument that the direct supply was cheaper where they were not dealing with straggling districts, and the question here was really one of districts of manageable size. The London Company had pushed the transformer system to its legitimate consequences as far as electrical engineering was concerned, and made it possible to fix upon any part of their enormous area and light it from Deptford. Supposing they got their area, they would be able to do the best piece of the City for its day lighting, and the best piece of Chelsea, which would strangle the Chelsea Company, and the best pieces of the Strand and Marylebone. They had adopted a system which would enable them to take all the plums in the way of lighting over their area. He wanted to contrast the aims of the Board of Trade in 1883, and their means of carrying them out, and what were the aims of that company, and their means of carrying them out. The object of the Board of Trade was not to let a company have powers over a district unless there was a reasonable certainty that they would put the electric light within the reach of the whole of the people of a district. Certain districts were only with great difficulty given to the companies, and the only reason why the power of extension was given to them was that if they took the pioneer risk, it was only just to give them the chance of a moderate extension without having to go to the expense of a further application to Parliament. But the Board of Trade knew that the only object of such companies was to develop electric lighting. They had no opportunity of picking out the plums, and the allocation of capital was required. It was, moreover, understood that if they did not succeed in doing their work, other companies would be allowed to come in, a fact which they embodied in the well-known clauses of the model order. Now, he accused the London Company of deliberately intending to take the plums. What did the London Company undertake to do in the way of actual works? Not one single yard of main did they undertake when they lodged their order. They now undertook to do in Chelsea the same compulsory works as the Chelsea Company undertook to do in 1886 in order to get their small area. It was to give a mock appearance of equality with the Chelsea Company. The London Company had, moreover, left out the clause, "capital allocated to do these areas," with the obvious reason that they intended to light such bits as would prevent any other company coming in and doing their leavings, or even in competing with them in places which they did light. They had omitted that clause because it was fatal to their scheme. As to the cry of "no monopoly," there was nothing to justify the Board of Trade in now coming to a conclusion different from what they did in 1883, that potential competition and judicious districting were better for the public than competition within the same area. With regard to the breaking up of the streets, the matter stood where it did before, and the Board of Trade was not now willing to permit overhead wires any more than it was in 1883. The third thing that the Board of Trade relied upon was gas competition. Looking at what gas could do in 1882, he had no hesitation in say that competition was now much more severe since the gas companies had awakened up from their lethargy. Even mineral oil was a much more efficient rival than it was in 1882. If the rivalry to the electric light was considerable in 1882, it was much more considerable now. What justification was there for supposing that the gigantic system of the London Company would lead to cheaper electric lighting? Their charge of £5 a quarter did not look as if they were to do any small lighting at all, and there was no evidence that they did not mean to go up to their maximum. If the scheme broke down, it would discredit electric lighting altogether. As to the E.P.S. orders, the two parts applied for were Paddington and the Strand. He did not think that the Vestry would continue their opposition to a well-considered scheme. They were willing to allocate the capital, and had undertaken to put down £30,000, which, he thought, was all that could be desired.

Mr. C. A. Cripps afterwards replied for the Metropolitan Company, and in the course of his address said that Mr. Moulton had based his argument on two contentions: first, that districting, as against competition, was settled once for all by the Board of Trade in 1883. So far from picking and choosing, his company put the whole district on an equal footing. They had made arrangements for generating stations for 350,000 lights, they had 700 shares, their capital had been subscribed by the public nearly twice over, and they had power to increase it. The Chelsea Company, in contradistinction to them, was in the hands of contractors. In Paddington the E.P.S. Company were competing with the Metropolitan Company, which applied for the whole of the district, while the E.P.S. Company applied for only a part, and Mr. Dethridge had expressed a decided preference for the Metropolitan system. They had the assent of the Marylebone Local Authority. With regard to the South London order, Lambeth said that they preferred the Metropolitan to the London Company's system, because the former applied for the whole district, whereas the latter sought only about a fourth, picking out the best parts. It was very improbable that the Metropolitan Company, however, could comply with all the conditions desired to impose. Wandsworth wished them to go there, the local authority making as good terms as it could. There was no competition in Wandsworth, it being merely a question between the company and the local authority.

TUESDAY, APRIL 30.

Mr. C. A. Cripps, in continuation of his address for the Metropolitan Company, said that there were only a few preamble objections to his Mid-London order. They were urged by St. Margaret's and St. John's, Westminster, for the City, and the St. Giles's District Board of Works. St. Margaret's and St. John's said, "We think all provisional orders should be refused, and that the local authority should be allowed another year to consider the whole question." No evidence had been given on behalf of the Vestry, and he did not know why objection was taken. The Vestry had, however, specifically laid it down that if any order were to be granted they would be in favour of competition. As regarded the objection of the City to the system, he would say without hesitation that every criticism which had been advanced by Mr. Russell Griffiths was not against the Metropolitan Company, but against the London Electric Supply Corporation. No one electrical difficulty had been put forward as militating against the Metropolitan Company. He submitted that having modified the term of 21 years for purchase to 42 years, and having regard to Mr. Preece's opinion that the converter system with central stations was the best for the City, and that the Metropolitan Company were willing to go into it, there was nothing which ought to keep the City and the company apart. As to the Strand agreement between the District Board and the Metropolitan Company, Mr. Pember, on behalf of the London Company, had urged that it was an improper agreement, which should not be sanctioned by the Board of Trade, and that it was contrary to the policy of Parliament, as shown

Digitized by Google

by the Electric Lighting Acts. Mr. Jones, for the St. Giles's district, took an entirely different attitude. He said that it was a very proper thing for the company and the local authority to come to such terms, but asked why similar terms should not be granted to the body he represented. There had been a suggestion of unfair advantage shown to the Metropolitan Company. The evidence amounted to this, that a letter was sent in identically the same terms to the London and the Metropolitan Companies, which was followed by negotiations with both companies; but as regarded the London Company those negotiations came to nothing, whilst they ultimately ended in an agreement with the Metropolitan Company which was now before the inspector, and the only possible suggestion of unfairness was that the Strand Board of Works did not disclose to the London Company the terms on which they were negotiating with the Metropolitan Company—which he ventured to say would have been an improper thing for that body to do. He then went into a detailed explanation of the various clauses in the agreement. He next came to the clause suggested by Mr. Moulton to protect the telephone companies. Mr. Moulton seemed to argue that the electric light companies were creating a nuisance, and they must for all time protect anyone who might be affected by the nuisance thus created, and therefore not only as regarded existing telephone wires but those which might be laid down in the future, they ought to come under terms to provide against all possible damage. He (the speaker) thought that a monstrous assumption. The right principle was that where a telephone company had laid down their system, and were in occupation, they had a right to be protected against any second company seeking to come in. Where they were first in possession they were entitled to the rights they had got, and if those rights were interfered with full compensation should be given. But if the Metropolitan Company were first in possession, they had a right to be protected in the same way. He then came to the subject of motors, and said that the evidence of the scientific experts was to the effect that the alternating system could be used with motors. In the system of the London Company he contended that there were many difficulties which Mr. Ferranti had not told them how he proposed to overcome. The London Company had not had a single expert to back up Mr. Ferranti, and he believed that there was an overwhelming preponderance of the scientific evidence in favour of the alternating system which his clients proposed.

Mr. Pember then commenced his reply on behalf of the London Electric Supply Corporation, and said that his case and that of the Metropolitan Company were undoubtedly the most important of the enquiry. The London Company would spend the whole of its £800,000, or more, if necessary, in lighting the district it had undertaken to supply. If at the end of 42 years the local authority bought up the undertaking without the station at Deptford, the plant there would remain in the hands of the company, but he was not at all afraid of such a contingency. A moderate-sized room would suffice for the distributing stations of the London Company. The reduction of the voltage from 10,000 to 2,400 was not experimental, but was being actually done at that moment. Their system, so complete and simple, was by far the newest and greatest stride taken in the application of electricity for many years.

WEDNESDAY, MAY 1.

Mr. Pember continued his address on behalf of the London Company, and said that he had been told that the inspector had stated at Brighton that the Board of Trade had determined not to adopt the new unit.

Major Marindin said that that was the case. He had been informed by the Board of Trade that they had decided to retain their own unit and not to take up the new one.

Mr. Pember urged that they should adopt the larger unit of 10,000 amperes, as in the case of the London Company, rather than that of 1,000 amperes, for the reason that was the price at 7½d. as was now charged at the Grosvenor Gallery. The smallest reduction which they could make in the charge would be ¼d., which would represent a reduction of 3 per cent., whereas in the case of a gas company, with the unit of 1,000 cubic feet, and a charge of 3s. 2d., the reduction was not of such serious consequence. It was impossible, he then proceeded to say, to conceive any simpler or better method for the supply of electricity to London than that of the London Company. The objection that had been raised constituted every objection which hostility, self-interest, and ingenuity could raise. The first objection was that of short-circuiting, which was connected with the joint, but Mr. Ferranti was not afraid of that, because experiments had been made from day to day during the enquiry, which resulted in showing that those joints had been found to stand an enormous pressure. Even Mr. Preece, when asked if the proposal of the London Company was a reasonable one, said it was simply a gigantic experiment, and a matter of pounds, shillings, and pence. Even from a commercial point of view, that witness was not against the London Company, although he favoured the alternating system to the transformer. His objection was to the connection between London and Deptford by their mains, but everything else he admitted to be workable. His objection related to the question of insulation and earthing, and he said the difficulties he anticipated were in connection with the insulation of joints, and with the disturbance of the electric and telegraph wires. But the London Company were willing to meet all the objections of the Post Office, and experiments were now going on with that object. The most important admission was that a cable could be made which would convey the current from Deptford to London, which would get rid of the Post Office objections, and ensure the safety of the public. Dr. Hopkinson admitted, dealing with the question of electrostatic induction, that there would be no difficulty with regard to the telegraph and telephone wires, if they were properly arranged. He would not recommend any rearrangement of those wires, but a proper arrangement of the electrical conductors, so that it would be quite unnecessary to disturb the telegraph and telephone lines in any way whatever. Sir William Thomson had given similar evidence, and said that he did not anticipate any of the difficulties referred to. Coming to the question of short circuiting, and the probabilities of a "flare-up" resulting from a breakdown referred to by Mr. Crompton in his evidence, that witness had admitted in cross-examination that the accident of this kind he once saw might have been the fault of the fuse, and that Mr. Ferranti would no doubt design a proper fuse. He thought that since Mr. Crompton put the process of the restitution of the light after a breakdown at half a minute only, and Mr. Swinburne at two or three seconds by the London system, he (Mr. Pember) thought that they could afford to ridicule all the silly talk about panics in theatres and such places. That difficulty had been spoken of in connection with the working of transformers, but it had been overcome long ago. The objection as to the dangers of transformers in private houses was answered by Mr. Heaphy, of the Phœnix Fire Office, who said there was no danger at all. After dealing with the agreement between the Strand District Board of Works and the Metropolitan Company, which he characterised as being contrary to public policy and the spirit of the Acts of 1886 and 1888, the learned counsel said that he did not think there was anything in the attitude of the local authorities which would prevent the orders being given *sub modo*, leaving to the Board of Trade the decision of details afterwards. He concluded by thanking Major Marindin for the patient and able manner in which he had conducted the enquiry.

Major Marindin, who said that it would be his duty to prepare without delay his report to the Board of Trade, briefly returned thanks, which closed the enquiry.

COMPANIES' MEETINGS.

SUBMARINE CABLES TRUST.

The eighteenth ordinary annual meeting of the certificate-holders in the Submarine Cables Trust was held on Friday last at the offices, Winchester-house, Old Broad-street.

Sir John Pender presided, and, in moving the adoption of the report, said the revenue for 1888 was £17,948, as against £19,018 in the past financial year. As mentioned at the last meeting, the certificate-holders for the two previous years received payment of their coupons at the rate of 4½ per cent., while for the year ended April last they had a return of 5⅝ per cent. They had not been disappointed with the estimate of revenue for the current year. Their coupons were cumulative, and were influenced by the success or otherwise of the respective companies in which they held stock. The active competition in the Transatlantic cable traffic had in the past resulted in the returns of the companies being small, which, in turn, had affected the trust. But things were now more settled in the telegraph world, and he thought they might look confidently forward to better times. Intimately connected, as he was, with the various telegraph companies, he believed their present prospects were favourable. With an improving trade, there had been an improved traffic, and there had of late been a marked increase in the returns. They had a large investment in the Anglo-American cable companies, and it was satisfactory to know that the Transatlantic traffic was likely to grow at the shilling rate. They expected that, if things turned out well, they would receive a return of £3. 17s. per cent. upon their investment.

The **Marquis of Tweeddale** seconded the motion, which was agreed to unanimously.

THE SUBMARINE TELEGRAPH COMPANY.

An extraordinary general meeting of the Submarine Telegraph Company between Great Britain and the Continent of Europe Limited, was held on Tuesday at the offices, Throgmorton-avenue, E.C.

Sir J. Goldsmid, M.P., who presided, stated that the shareholders would, no doubt, have been surprised at being summoned to another meeting, but the reason was very simple. Theirs was a chartered company, and the proceedings for a chartered company were not exactly the same as for a company established under the ordinary company law. They had thought, if they passed the resolution suitable for a chartered company to pass appointing liquidators and authorising a liquidation, that that would be sufficient, but as their Company was also registered under the Companies Clauses Act, the solicitor to the Post Office was of opinion that it was desirable that the resolution should be passed under that Act in addition to the resolution they had passed as a chartered company. He concluded by proposing a resolution winding up the Company voluntarily under the Companies Acts, 1862 and 1867, and appointing Sir J. Goldsmid (the chairman of the Company), the Hon. Henry R. Brand (a director), and Mr. S. M'Donnell Clare (the secretary) the liquidators.

The **Hon. Ashley Ponsonby** seconded the motion.

The **Chairman**, continuing, stated that they were proceeding satisfactorily with the liquidation. They had arranged with the Government for a sale of the cables at a price—an inadequate price; and they had also arranged for the sale of the house in which they were then assembled, and for the disposal of their steamer; and, in fact, of all their property. The Déolen cable, which had belonged jointly to the Company and the Paris and New York Company, would in future belong absolutely to the latter, who would pay the Submarine Company half price, as was originally arranged in the agreement which

Digitized by Google

had been entered into between them. Practically, the only thing they had to settle now was as to what was to be done with the Salcombe cable; but that was a matter which would require still further negotiation and consideration. He had every hope that in the course of a fortnight, or at the outside three weeks, they would return a very substantial part of the capital to the shareholders, and they hoped that in the course of three months the liquidation would be completed. They had probably seen the very heated discussion which took place in the House of Commons as to the price the Government would pay them and the amount they had awarded as compensation to the employés of the Company whom they did not take over. He did not think it was desirable that he should discuss the proceedings of the House of Commons. The resolution having been put and carried, the Chairman stated that the meeting to confirm it would be held on the 19th prox. He added that he did not think it necessary to put the other resolutions which were passed at the last meeting, although it was announced that that would be done. It might be advisable to pass the following one: "That the liquidators be empowered to negotiate and sell, at a price to be fixed by valuation, or otherwise, the Salcombe and Déolen cables, belonging partly to the Company and partly to the Société Carmichael et Cie."

The **Hon. A. Ponsonby** seconded the motion, which was adopted.

Mr. Russell Griffiths thought it would be advisable for the other resolutions, of which notice had been given, to be put, which was done, and they were carried after a short discussion.

The **Chairman** afterwards proposed the resolution authorising the liquidators to supplement the money which the Government had agreed to pay to the employés in England of the companies not taken into the service of the Government by a further sum not exceeding £500.

The **Hon. A. Ponsonby** seconded the resolution, which was carried unanimously.

The **Chairman** stated that they had now passed all the resolutions except the one authorising the Government to work the cables from April 1. As the Government had worked them from that date, he thought it unnecessary to pass a resolution authorising them to do so.

Mr. King and **Mr. Pawle** afterwards addressed the meeting, the former complaining of the action of the Government towards the Company, and the latter asking for information to account for the difference between the £330,000 of capital expended, and the £100,000 which the Company would receive.

The **Chairman**, in reply, said he could agree only with some of the remarks that had been made. He agreed that they were getting a very poor price for their property, but he could not agree that the Government ought to pay them the price of new cables for old ones. Those who had paid a high premium for their shares would not get such premium back, but many who had paid a high premium for their shares had been receiving large dividends, and if they had acted wisely they had put by a considerable proportion of their dividends as a sinking fund for their capital. He agreed that the Company had not been handsomely treated, but he could assure the shareholders that the Directors had done their utmost to obtain the best possible terms. They must accept the position, which was disagreeable, but which might have been worse had not the shareholders and the Directors been a little provident.

The proceedings then terminated.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for the week ended May 24 amounted to £5,313.

Western and Brazilian Submarine Telegraph Company.—The traffic receipts for the past week were £3,813.

Business Note.—Messrs. W. H. Wilcox and Co., of 36, Southwark-street, inform us that having purchased the premises, business, goodwill, and stock of W. Goodwin and Co., 36, Primrose-street, leather machine band, etc., manufacturers, they are now in a position to give special attention to this department.

Spanish National Submarine Telegraph Company, Limited.—The numbers are announced of 72 bonds, amounting to £7,200 of the Spanish National Submarine Telegraph Company, Limited, 6 per cent. mortgage debentures to be paid off at par at the offices of the Company, 106, Cannon-street, E.C., on and after June 29 next.

Liverpool Central Hydro-Electric and Massage Company.—This Company has been registered by Hughes Quilliam, 6, Parker-street, Liverpool, with a capital of £500, in £1 shares. Object: to acquire the Russian, Turkish, and Electric Baths, situate at 3 and 5, Cases-street, Liverpool. Registered without articles of association, and consequently the regulations of table A in the first schedule of the Companies' Act, 1862, apply.

PROVISIONAL PATENTS, 1889.

MAY 20.

8360. **Improvements in apparatus relating to telephone systems.** Fred. A. Holcomb, 18, Buckingham-street, Strand, London. (Complete specification.)

MAY 21.

8390. **Improvements in electric motors.** William Morris Mordey, 46, Lincoln's-inn-fields, London.

8400. **An improvement in electric bells.** John Megson Porter, 34, Ebor-place, Leeds.

8451. **Improvements in conduits for electric light and other wires.** George Gollop, 70, Chancery-lane, London.

8453. **Improvements in regulating electric currents.** William Morris Mordey, 46, Lincoln's-inn-fields, London.

8456. **Improvements in portable electric safety lamps.** Lars Bristöl, 70, Chancery-lane, London.

8459. **Improvements in dynamo electric machines and electric motors.** Thomas Leopold Willson, 55 and 56, Chancery-lane, Middlesex.

8460. **Improvements in coating and protecting wires for electrical, telephonic, and other analogous purposes, also applicable in the manufacture of tubing.** George France and Eli Holroyd, 8, Quality-court, London.

8468. **Improvements in tramcars, locomotives, or other vehicles driven by electricity.** Thomas Drake Hollick, 35, Southampton-buildings, London.

MAY 22.

8493. **Improvements in automatic cut-outs for electric circuits.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

8528. **Transmission of power by alternate electric currents and apparatus therefor.** John Hopkinson, 47, Lincoln's-inn-fields, London.

MAY 23.

8557. **Improvements in or relating to meters or instruments for measuring currents of electricity.** Mark Parker, 323, High Holborn, Middlesex.

8559. **Improvements in securing telegraph wires to insulators.** William Osberne and James Salter Scales, 23, St. Stephen's-street, Tonbridge, Kent.

8569. **Insulating and suspending wires, cables and conductors for electrical currents.** Wallace James Lambert Sandy, 36, Maxted-road, East Dulwich, London.

8588. **Improvements in alternating current dynamos and motors.** James Swinburne, 49, Queen's-road, Wimbledon.

8606. **An improved form of secondary battery for the use of miners and the like, and lamp mount for same.** Mark Bailey and John Warner, 21, Finsbury-pavement, London.

8614. **Improvements in electric lampholders or coupling pieces for use in series circuits.** Albert Augustus Goldston, 4, South-street, Finsbury, London.

8619. **An improved electrical alarm for audibly indicating and announcing the varying water levels of steam boilers and the like.** Andrew Siegmann, 20, High Holborn, London. (Complete specification.)

MAY 24.

8631. **An improved portable electric lamp and battery.** Robert Thompson and Horace Seymour Pyne, 27, King-street, Liverpool.

8657. **Improved methods and appliances for conducting and distributing electric currents.** Edward Brailsford Bright, Francis William Engelbach, and John Brailsford Bright, 31, Golden-square, Regent-street.

8674. **Improvements in connection with electrical tramways or railways.** John Hopkinson, 47, Lincoln's-inn-fields, London.

8692. **Improvements in multiple switchboard systems for telephonic exchanges, and wire bands to be used therein.** John Edward Kingsbury, 24, Southampton-buildings, London. (The Western Electric Company, United States.)

NOTES.

Overhead Pole.—The city of Mexico is following the example of New York, and proposes to remove all electric wires from its streets.

New Journal.—We have received a copy of a new Spanish journal entitled *El Telegrafista Espanol*, dealing with matters electrical, published in Madrid.

The London Electric Corporation.—Mr. James Staats Forbes has joined the board of the London Electric Supply Corporation, Limited, as deputy chairman.

Dock Lighting at Belfast.—Messrs. Crompton and Co. have secured a large order from Messrs. Harland and Wolff, shipbuilders, of Belfast, for arc lamps and dynamos.

Execution by Electricity.—The American Government have purchased three sets of dynamos and apparatus for execution of criminals, to be placed at Sing Sing, Auburn, and Clinton prisons.

Fluted Carbons.—M. F. Carré, the well-known maker of carbons in France, points out that fluted carbons claimed as first used by Sir James Douglass, were patented by him as long ago as November, 1881.

Incandescent Lamp Patents.—Is it a fact, as rumoured in Paris, that the Edison Company have lost an action lately instituted against the Khotinsky Company for infringement of incandescent patent rights ?

Frankfort.—The river harbour at Frankfort-on-Main is now lighted by 15 1,000-c.p. arc lamps and 73 incandescents on the transformer system, supplied by the "Helios" Company, of Cologne and Ehrenfeld.

American Engineers.—A large number of American engineers, in all about 250, arrived in Liverpool this week on board the "City of Richmond" and the "City of New York," on their way to London and the Paris Exhibition.

Italy.—It is stated that the towns of Florence and Pistola have granted concessions for the establishment of central electric light stations for public and private lighting to the Société Belge d'Electricité, represented by M. Léon Gerard, of Brussels.

The Seel Lamp.—A limited company has just been formed in Belgium for the manufacture of the Seel incandescent lamps, with a capital of 5,000,000f., under the name of the "Société Anonyme Belge pour la Fabrication des Lamps Electrique à Incandescence."

Republic of Columbia.—Electric lights are needed in the Republic of Columbia, the Government being in favour of extension in this direction. Special concessions will be made to electric light companies for the period of twenty-five years for lighting the different cities.

Proposed Submarine Cable.—The Spanish Government will receive up till the 20th June next, at the offices of the Minister of Colonies, Madrid, tenders for the laying of three submarine cables between the islands of Luzen, Parray, Negus, and Cuca, a total length of about 200 miles.

Leeds.—The Leeds Corporation seem inclined to take up the question of electric lighting in a practical manner. The borough engineer of Leeds, at the last meeting suggested the expenditure of £60,000 for a central station. It was decided to print the report, and adjourn the meeting to June 12th for discussion.

West Coast Cables.—The Eastern Telegraph Company notifies the opening for traffic of the Eastern and South African Company's new West Coast cable to Cape Town, thus affording an alternative means of telegraphic communication with South Africa. Telegrams can be sent by the East or West Coast cable routes at the same tariff.

Railway Lighting.—The Chesapeake and Ohio Railway have just received some new cars from the Pullman Company. They are fitted throughout with electric light; the Eickmeyer dynamo, Brotherhood engines, and the Electrical Accumulator Company's storage batteries are used. The whole of the passenger trains on this line will be lighted by electric light.

Mulheim Cables.—We have received a pamphlet, with reference to the goods of Messrs. Felten and Guilleaume, wire and cable manufacturers, of Mülheim-on-the-Rhine, near Cologne. The pamphlet is issued by Messrs. W. F. Dennis and Co., 11, Billiter-street, E.C., and is indicative of the position the firm are now taking in this country in the supply of wires and copper cables.

Dinner to Prof Elihu Thomson.—Prof. Elihu Thomson, of Thomson-Houston world-wide celebrity, is expected in England this month, and the Laing, Wharton, and Down Construction Syndicate, Limited, intend to welcome him on his arrival by giving him a reception and dinner at The Ship, Greenwich, where a number of English electrical celebrities are invited to welcome their American *confrère*.

Denmark.—Copenhagen is one of the few towns on the Continent possessing its own gas works, and will probably soon possess its own electric light station. One of the chief engineers has recently been on tour to visit the principal large central stations in London and Germany, and plans are being prepared for a station for 10,000 lights, with capacity for doubling the output when required. Stockholm and Christiania are also moving in the matter of central stations.

The Edison Patents.—The law case between the Sawyer Man and the Edison companies has recently been brought before the courts at Pittsburg, and, according to the New York *Tribune*, Edison's counsel now abandons the claim for fibrous materials for incandescent lamps, saying that they were used by many inventors since the days of Sir Humphry Davy. It seems rather peculiar that the very facts relied upon in English courts are not claimed by Edison in America.

Electric Mining Stamps.—Despatches from Auckland states that gold has been found on the Nenthorn reefs, and the erection of a crushing battery with electricity as the motive-power is advised by Mr. E. Foord, who has visited the district. One of the samples of quartz is from a newly-discovered reef about a mile from any other line on the field. It is a very rich specimen, being thickly studded with gold. A company is being formed among the various holders of leases to arrange for the erection of the crushing machinery.

Double Lamps.—Another sweeping claim is being made in America. The Brush Electric Company, of Cleveland, are notifying local authorities not to use double lamps in lighting the streets unless manufactured by the Brush Company, as they claim that all double carbon lamps were infringements on patents granted to C. F. Brush. The company state that they intend to institute proceedings against all manufacturers of double lamps, as well as

Digitized by Google

against all those using a differential magnet in their lamps, either double or single.

The Baxter Motor.—It was intended to exploit the Baxter motor in England if we may judge from the following, but the intention has had to be dropped: Angus Cameron and Thomas Gemmell, of London, and Malcolm Sinclair, of Cumberland, Maryland, U.S., have sued the Baxter Company for fifty thousand dollars for breach of contract. A syndicate was to be organised in London, but the negotiations fell through on account of complications in the business of the Baxter Company. Their business is evidently still more complicated now.

Paris Jury.—The following are the members of the jury of the electrical section for the Paris Exhibition: MM. Fontaine (Société Gramme), Fribourg (Government telegraphs), Huet (sous-directeur of works of Paris), Mascart (membre de l'Institut), Postel-Vinay (engineer), Potier (professor at l'Ecole Nationale), Sciama (director of the firm of Breguet), Sébert (colonel, director Marine laboratory), Trotin (post and telegraph office). Supplementary members: MM. Jousselin (P.L.M. Railway), Rau (Edison Company), Sautter (Sautter-Lemonnier and Co.).

The New Telephone Company.—The business of this company has come to an end owing to an action which had been brought against them by the United Telephone Company, in which an injunction had been granted restraining the New Telephone Company from manufacturing telephones, on the ground that they were infringing the patents of the United Company. Under these circumstances resolutions had been passed by the shareholders for a voluntary winding-up on Monday last, and the usual supervision order was made upon the petition of the company.

The Waterhouse System.—Since the acquisition of the Waterhouse arc lighting system by the Westinghouse Electric Company, of Pittsburgh, according to American advices, great progress in the introduction of this system has been made. The works have recently been removed from Hartford to Pittsburgh, and the Westinghouse Company have just issued a second list of installations, comprising 800 lamps, carried out during the past six months. We note, also, that they have just secured a contract for installing 500 Waterhouse arc lamps of this system for lighting the streets of Philadelphia.

H.M.S. "Marathon."—The trial of the engines of H.M.S. "Marathon" took place at Portsmouth last week. The ship has been furnished throughout with the latest improvements. Voice-tubes and electric bells connect the conning tower and bridges with the captain's and chief engineer's berths, engine-room, and stokeholds. The ship is also fitted with electric steering gear, electric counters, and electric revolution indicators; while the electric light, which includes three powerful search lights, is supplied from two duplicate engines, one being stationed in the engine-room and the other in the dynamo-room.

Holiday Rejoicings by Telephone.—A lady editor in Philadelphia who takes her press news over the long distance telephone from New York in order to hear more distinctly, wears a metal cap attached to a receiver, which presses close to her ear. During the recent naval pageant at New York to welcome the arrival of the President, she distinctly heard the whistles of the steamers, the roar of the artillery, and the bells of Trinity Church. On the next day the strains of martial music and the hurrahs of the assembled crowds were plainly borne to her ears, the first time probably that outside sounds of this nature have been distinctly heard over some hundreds of miles.

Johannesburg.—In the upper Southern African goldfields, towns are springing up in marvellous fashion we are accustomed to connect with America only. Johannesburg is one of the most prosperous of these, and is now a large and well-developed town with many thousands of inhabitants, where a few years ago there was little but a few squatters. Squares and streets with large and fine buildings and offices have sprung up, and the lighting of these is at present a matter of interest. The Johannesburg Gas Company are putting up large gas works, designed and constructed in England, and electric lighting is also likely to be in request. It is probable that an active agency, both for electric lighting and also for electric transmission of power, would result in good business from the new goldfield towns of Africa.

The Spanish Exhibition.—The electric lighting of the exhibition at Earl's Court, the Spanish Exhibition, is this year on a low-tension system, the Gulcher Company having secured the contract. The machinery is in the same situation as last year, and already 185 arc lamps are lighted from this dynamo-room, as well as some 200 incandescents, which will be soon considerably increased in number. Eight Gulcher dynamos of various sizes are now installed, and others are to be added. The engines are 30 h.p. nominal semi-portable type, working up to about 100 h.p. each, two of them being Marshall's engines, and one Ruston, Proctor, and Co.'s; another of the latter is to be fixed shortly. The potential of the circuits is 65 volts, the arc lamps being run in parallel on the Gulcher system.

Train Lighting.—As the electric lighting of trains is now in a fair way to be widely adopted on many lines, an economic hint from previous experience of gas may not be out of place. In a most interesting book upon "The Railways of England," by W. M. Acworth, it is mentioned in a footnote that the engineer of the Paris, Lyons, and Mediterranean Railway has stated that he has economised £4,000 a year by connecting the taps of the gasjets with the night caps of the carriage lamps, so that when the cap is drawn over the glass the gas is turned down to a mere glimmer. This is a large sum, and it is hardly likely that so much would be saved by turning down the electric light (it should not be turned quite out), but means for doing so on the night trains should not be omitted, both on this score and on that of comfort to the eyes of sleepers. In the same book it is mentioned that the comparative cost of oil, gas, and electricity is as 1 : 1¼ : 1½.

Magnetic Separation of Ore.—Mr. Josiah T. Smith, in his address as president of the British Iron Trade Association, at the Westminster Palace Hotel, referred to the fact that magnetic separation has been resorted to in some parts of the American continent, with a view to eliminating from impure ores the deleterious ingredients that unfit them for the production of high-class metal. This, he said, would be another factor in fixing the probabilities of the future of the iron ore trade that must not be lost sight of. Whether the magnetic separation of iron from the materials with which it is found associated in nature is at present an assured economic success or not, so much has been actually done in this direction by Wenström and others as to justify the hope that we shall see applied to ores *per se* as effectual treatment with a view to getting rid of phospherus and other metalloids as we have already seen

Digitized by Google

applied to the treatment of impure iron by the basic process.

Charing Cross.—The Works Committee of the St. Martin-in-the Fields Vestry on May 30 reported on a letter from the County Council addressed to the London Electric Supply Corporation, declining, in the absence of any statutory powers possessed by the corporation, to grant the use of subways for the purpose of laying electric cables. There was also a letter from the corporation applying for permission to lay two 4in. pipes under the roadways from Peabody-buildings at the corner of Chandos-street and St. Martin's-place, across Charing-cross-road, and along Green-street to No. 21 therein. The committee recommended that the application be granted. Some objection was raised by members living in the district on the score of inconvenience to traffic, but it was remarked that the application was only a small matter—only two pipes, and not a subway, and there would be no pulling up of the streets—and that the time had come for electricity to supersede gas, which was inadequate. The application was then granted, the time for commencing the work to be fixed by the surveyor.

The King's College Engineering Society.—On Thursday last Mr. Chas. Mittelhausen read his presidential address to the Engineering Society at King's College, Strand, on a few recent engineering advances. The author showed experimentally on a small scale how sewage could be precipitated electrically by means of iron electrodes, and indicated how this long-known scientific fact had been turned to practical account in the Webster process. The series system of electrical traction was then described, and the working shown by means of a model. Speaking on the advantages of photography for engineers, Grimston's new patent shutter was mentioned on account both of the simplicity and accessibility of its mechanism. The author also referred to Messrs. Siemens Bros.' new Morse instrument, whilst with reference to the question of national defence some of the newest methods of operating submarine mines was explained. In the civil engineering world the chief features of the Forth and Lansdowne bridges were described, and the address terminated with some remarks upon the usefulness of the Eiffel Tower. A cordial vote of thanks was given to Mr. Mittelhausen for his interesting paper.

Chelmsford.—At a meeting of the Chelmsford Town Council on May 29, the Lighting Committee reported that the draft contract with Messrs. Crompton and Co. had been finally settled, and they offered as sureties for the due performance of the contract Viscount Torrington and Sir Charles Grant. The committee recommended that these gentlemen be accepted. The committee further recommended certain slight alterations in the scheme. In reply to Alderman Dutton, the Mayor said that if the light failed the fine would be £500. The motion for approval and sealing of the contract was carried. Alderman Gray said he thought the thanks of the Council were due to the Lighting Committee for the immense trouble they had taken in the matter. They hoped the lighting would be a success, but if it was not it would be no fault of the committee. A discussion took place as to whether a license should be taken out, and Councillor Albright said he should like to have an opinion from the Council as to whether they intended to proceed in the matter. His firm (Messrs. Crompton and Co.) had taken all the preliminary steps to procure a license, but if the Council intended to get one themselves Messrs. Crompton would of course not proceed with their application The question was referred to the Lighting Committee.

Central Lighting in Birmingham.—The difficulties attending the negotiations for a central station in Birmingham appear to have been satisfactorily settled, and it is anticipated that the provisional order promoted by Messrs. Chamberlain and Hookham will now be granted. The final form, as settled by the promoters in consultation with the Board of Trade and the Public Works Committee, limits the provisional order to a restricted area of the city, composed principally of Market Hall Ward. The promoters will be required to form a capital of £50,000. On some disputed points of procedure, including certain protective clauses usually required by the Corporation to be inserted in local Acts of Parliament, Messrs. Chamberlain and Hookham are willing to submit to the usual conditions. With regard to certain objections made to clauses in their own and in the London and other provisional orders, the promoters agree to accept the general ruling of the Board of Trade. The stipulated company will be formed immediately on the confirmation of the provisional order. Messrs. Chamberlain and Hookham have, we are informed, served the necessary notice upon the Town Council to enable them to apply next session for a further provisional order for a more extended area than that for which the present arrangement deals with.

Mayfield's Catalogue.—We have received a copy of the catalogue of Messrs. Mayfield and Co., Limited, of 41, Queen Victoria street. This firm (who, by-the-way, we note, have just altered their title from that of Mayfield, Cobb, and Co.) keep in stock and manufacture a large number of electrical instruments and apparatus, batteries, bells, indicators, lamps, and measuring instruments. We note their burglar alarm contact, and their double-lock indicator movement, in which the flag works in any position, both useful inventions. Also a large number of scientific and teaching apparatus, which the firm manufacture themselves. The Wimshurst machine is a speciality of this firm illustrated in the catalogue. Several of the larger size of Wimshurst machines have lately been supplied to the Deptford station for testing the high-tension dynamos, and to Messrs. Felten and Guilleaume, who are manufacturing the Ferranti cables for testing insulation. Another of these large machines, giving a 13in. spark, will be on exhibition at Paris. Mr. Mayfield, who for a long time was manager for Mr. J. W. Swan, at Newcastle, has a number of interesting instruments and fittings at his premises, and turns out a considerable amount of work in the manufacture of electrical requirements. His partner, Mr. Todman, has patented sundry ingenious instruments and improvements, and we note among the proprietors of the limited company into which the concern has been formed, the names of Sir Charles Forbes and Mr. Ince.

Telpher Lines and Progress.—The United Electrical Engineering Company have two further telpher lines under contract, one of 10 miles and the other of six miles long. The appreciation of this method of electric traction is spreading, and Mr. A. R. Bennett's recent remarks before the East of Scotland Engineering Association have served to point out that particularly in Scotland, as in other thinly populated hilly districts, light overhead telpher lines would prove profitable where ordinary railways, or even light tramways, would not pay. It is also a very great point in favour of the adoption of overhead lines for many situa-

Digitized by Google

tions, that no compulsory powers for buying land would be needed from Parliament; the immense outlay otherwise necessary for land would be also saved, and the line itself would be cheaper in construction than other lines. It is therefore no great wonder, now that the practical working details have been settled, that indications are forthcoming of the rapid extension of the telpher system, throughout Great Britain, as feeders to the main railway lines. From the colonies also we should expect good orders will be the result. The United Electrical Engineering Company appear to be laying themselves out for increased work in anticipation of telpher business. In other branches also, we are pleased to note, they are active, and some very commendable little pamphlets are either issued or in preparation to give full and accurate information in an intelligible style to proposing customers. One of these is on the above-mentioned "Telpher System of Cheap Transit," and another on "Machine Driving by Electricity" will prove useful to give suggestive information to factory proprietors. Electric lighting commercially considered comes into the scope of another of these pamphlets, and a separate one, in preparation, on electric lighting as applied to decorative art, deals with another phase of the United Company's operations.

The Sprague System.—Considerable surprise is likely to be expressed in connection with the Electric Works Corporation combination at the sudden prominence given to the Sprague motor in England, as little, if any, work has been done over here, although large numbers of electric railways are using Sprague motors in America. There, however, the work is nearly all upon the overhead system of conductors, a system practically impossible of introduction in English towns; and the present connection of Sprague with what will practically be an accumulator manufacturing concern lends some confirmation to what has been hinted, we do not know with what truth, that, in fact, Sprague is rather tired of overhead conductor systems, not finding in practice that simplicity in cars atones for the complication in the conductors and other apparatus. It certainly appears the fact the electric traction for cars in England seems to have a decided leaning towards the employment of storage cars in preference to conductor systems for streets; and a very large rush of business in this direction may be confidently expected, for English local authorities would strongly object to the long strings of posts and wires familiar to us in illustrations of the American street-railway practice. Storage batteries have now proved themselves capable of commercial employment for this purpose, and we learn that although by far the larger number of electric tramways in the States use the overhead system, nevertheless there are now upwards of 40 electric railways using or proposing to use storage batteries in the States. Many of these are naturally promoted by persons interested in the manufacture or supply of accumulators, while others are constructed by companies or local authorities after discussing the merits of both systems. It would be interesting to learn, after the experience, in some cases of a year or two's working, how far such pioneers of overhead systems as the Sprague Company have realised in practice the advantages of their systems, or how far their present ideas have been influenced by the comparatively later advances of the storage car.

The Telephone Amalgamation.—In the House of Commons on Monday Mr. R. Chamberlain asked the Postmaster-General whether his attention had been called to the tactics by which the financial group now commanding the telephone system of the kingdom had met his refusal to grant a license to the Amalgamated Company originally projected; whether his attention had been directed to the amount of capital to be created under the new scheme, and to the high charges to the public that would have to be maintained in consequence, and to the proportionately enhanced price that would be demanded should the nation ever decide to purchase; and whether under these circumstances he will at once avail himself of the right reserved under the agreement with the telephone companies, and "establish, extend, maintain, and work" a telephone system, such as would gradually bring the advantages of this invention within reach of the masses of the people. He wished to explain that the clerks had omitted a vigorous adjective which he had inserted before the word "capital." What he wished to call attention to was that this capital was not represented by any estate in the form of plant, buildings, wires, or instruments. It was a paper capital, and not a real capital. Mr. Raikes said, in reply to the hon. member, I have to state that I am aware of the proceedings of the telephone companies, and that the whole question of the telephonic service of the country is engaging my serious attention. I am not at all sorry that this question has been asked, as it may serve to direct public attention to a matter of extreme gravity, with regard to which expressions of public opinion may materially strengthen my department in protecting the public interest. The Postmaster-General, through the secretary of the Post Office, has written to the United Telephone Company to acquaint them, for the information of the directors and shareholders, that the amalgamation of the companies was not contemplated when the licenses were issued, and that any assurances, outside the licenses, which the companies may conceive themselves to have received from the then Postmaster-General cannot be regarded as applicable to the state of things likely to result from the proposed amalgamation.

Steam Trams Objected To.—A very good instance of the attitude which the public hold towards the steam trams was given on Tuesday, when Sir Michael Hicks-Beach (accompanied by Mr. Calcraft, C.B., Mr. Courtenay Boyle, C.B., and Sir T. W. P. Blomefield) received a deputation from the Wood Green Local Board with reference to the use of steam by the North London Tramways Company. Mr. Littler, Q.C., chairman of the Local Board, said the Local Board were not in existence when the company's Act was passed, or they would have opposed the granting of steam powers. They were constantly receiving complaints of the annoyance to the ratepayers, and on investigation they found that the nuisance was inseparable from the use of steam. Rateable values were seriously diminishing, and the practice was dangerous to the public. Accidents were occurring daily; only last Saturday an omnibus was overturned, and that morning it was announced that one of the passengers had died in consequence. An arbitrator was now enquiring into the question of terms, and the deputation asked that the question of whether steam should be used should also be referred to arbitration. They did not desire to stop the tramways, but the feelings against the use of steam was universal, and the road, which was just beyond the Parliamentary area, was as bad a road for steam as any of the metropolitan roads. Mr. Melluish, chairman of the South Hornsey Local Board, confirmed the statement made by Mr. Littler. Sir

Digitized by Google

Michael Hicks-Beach, however, could not see his way to interfere. He suggested that the courts were open to the Local Board, and this would be the proper procedure, rather than ask him to do anything which would be straining the power vested in the Board of Trade. We should imagine the trouble the North London Tramways Company are having with their steam trams should urge them, more particularly at this present juncture, to consider the adoption of electric traction, and not only from the absence of annoyance, but also upon the question of cost of running. It is suggestive also to compare the words used by Mr. Littler, that with the use of steam "rateable values were seriously diminishing," with those given with reference to the City of Richmond, Virginia, where it was pointed out that the introduction of the electric tramways had already increased the value of the surrounding properties. The crusade against steam in the streets has evidently commenced in earnest.

Lines of Electrical Induction.—In the *Scientific American*, R. W. Chapman, of the University of Adelaide, South Australia, gives an account of some very pretty experiments which may be made to show lines of electrical induction between two electrified bodies, by the use of the fine white needle-like crystals of sulphate of quinine suspended in a good insulating liquid, such as pure turpentine. To perform the experiments, he says, take a flat glass dish, and pour in turpentine to the depth of about a quarter of an inch, sprinkle this with sulphate of quinine evenly distributed till the turpentine assumes a milky appearance. If now a brass ball connected by a chain with an electrical machine be placed at one end of the vessel, and another connected with earth at the other end of the vessel, on working the machine the crystals of quinine will become polarised, and take up their positions end on end, forming very distinct curved lines between the balls in exactly the same way as iron filings form in lines of magnetic induction when sprinkled over a magnet. The symmetrical lines of white crystals when shown up by a dark background look extremely beautiful. We have here the basis for a set of experiments which may be diversified to an almost unlimited extent by varying the number and shapes of the electrified bodies placed in the turpentine. The fact that there is no electrical force within a hollow conductor may be very prettily shown by connecting both of the balls in the above experiment with the machine and placing in between them a large metal ring connected with earth. The curved lines are then very distinctly shown running from each ball to the ring, but within the ring the turpentine remains in the uniformly cloudy state in which it was initially, the crystals showing no disposition to place themselves end on end. The difference in the appearance of the quinine particles outside and inside the ring is very striking. If now a small third ball be connected with the machine and placed in the centre of the metal ring, the appearance of the turpentine within the ring is entirely changed, and the crystals form in straight radial lines from the centre to the circumference. By multiplying the number of the electrified balls, charging some positively and others negatively, the resulting lines of induction may be made very complicated, but, provided that there is a fair space between the balls, the lines are always distinctly and clearly mapped out by the crystals. It is an easy matter to obtain some very beautiful figures by symmetrical distribution of the electrified bodies. In making the experiments it is very necessary that the turpentine should be pure and dry, as a very slight amount of impurity is sufficient to destroy its powers as an insulating medium. Benzine will answer, and it possesses the additional advantage of not dissolving any of the quinine, while turpentine dissolves it to a slight extent, but its specific gravity is so small that the crystals fall to the bottom of the vessel almost at once, and adhere to it, so that they will not easily take up the lines unless the experimenter be sufficiently quick to electrify the balls before the particles reach the bottom. On the whole, turpentine I have found to give the most satisfactory results. After the crystals have once been electrified inductively in this way, they appear to take up the lines much more easily a second time. It seems as though the molecules do not recover altogether from the effects of the electric strain.

Electric Door Openers for Asylums.—Some few weeks ago we alluded to the electric door openers which had been fitted at the Milwaukee Asylum for Insane, Wisconsin. The superintendent, M. J. White, M.D., has recently described in detail his apparatus, which his committee, being strongly alive to the necessity for neglecting no practical means of safety, have granted him powers to fit to the doors. The lock is set into the door-jamb, and operates in connection with the bolt of the mechanical lock, which is of course situated in the door. In this manner the bolt of the mechanical lock is slid behind the bolt of the electrical apparatus, and held there securely by it until the current is turned on, when the electrical bolt recedes into the lock and releases the mechanical bolt. At the same instant a mechanical device, situate in the lock, in the form of a powerful spring push, and which is up to the highest state of tension when the door is locked, is released, and acting upon a small brass plate fastened to the door, serves to throw it a distance of three feet. The door is thrown open with its bolt shot and immovable, and cannot be closed again except by means of the key, as the electric bolt is immovable save when influenced by the current. This forms an advantage in preventing viciously inclined patients from securing themselves in their rooms or inveigling attendants therein and imprisoning them, as might happen in case a spring latch were used, as was suggested at one time. The device has the appearance of an ordinary lock, and nothing in connection with the system is objectionable as tending to suggest disagreeable associations, as the wires are all concealed under the mouldings of the door frames, and carried through the floor to the ceiling below in the basement, and along it to a locked cabinet containing the cells. At present the ten doors are operated by means of eight cells, the ordinary bell battery with sal ammoniac solution being used. A test of the apparatus is practically made every morning, as the patients are released in this way, and in case of any imperfect working the defect can be immediately traced and corrected, so as to ensure its efficiency in any event The push buttons are located in the attendants' rooms and are operated at that point, but in order to make assurance doubly sure, the wires are to be carried to the superintendent's office and are to be controlled from that point also. It is intended also to have a separate button to operate the exit and fire-escape doors, which will be used solely in case of emergency. This arrangement will provide a perfectly free exit from the building as well as from the sleeping-rooms.

ELECTRIC LIGHTING IN LONDON.

The Board of Trade enquiry recently held by Major Marindin was, amongst other things, for the purpose of investigating the nature of the systems of supply proposed by the various companies.

These were two in number, which may be referred to as the alternating-current system and the direct-current system.

Major Marindin, in his recommendations as to the provisional orders to be granted, has given by far the largest area to the companies adopting the alternating-current system.

It may therefore be advantageous to notice more particularly some of his findings as to this system and its rival, now practically ousted from London.

Speaking of the disadvantages of the alternating system, he says :

1. It necessitates great care and expense in insulation.
2. It involves some risk to life.
3. The main cannot be handled or connections made when the pressure is on.
4. The system cannot be efficiently utilised (a) for motive power, (b) for electric deposition, or other chemical uses such as charging accumulators.
5. The system depends entirely upon running machinery.
6. The engines and dynamos have to be kept in motion throughout the 24 hours.
7. The general efficiency must be low during 18 hours of every day on the average.
8. A serious accident in the generating station might stop the supply for a considerable time.
9. The measurement offers considerable difficulty, and with special reference to the London Electric Supply Corporation, he says—
10. That an accident, such as the bursting of one of the large steampipes, might have the effect of stopping the whole supply is certain.
11. The objection that the scheme of the London Electric Corporation is a gigantic experiment is no doubt in a certain sense true.

The only advantage found in its favour is that of "cost," an advantage that is immediately lost in the conditions imposed of duplicate stations and duplicate mains.

On the other hand, the only finding suggested against the direct system is that of cost.

But as this finding is said to be based on the evidence, and not on the conditions put upon the alternating companies, it is evident that even on the question of cost the result of the report is in the end favourable to the direct system.

The other findings in favour of the direct system are called *enormous advantages*, and thus described :

1. In the event of a total breakdown at the generating station supply can still be maintained for some hours.
2. It is not necessary to keep the machinery at the generating station in motion throughout the whole 24 hours.
3. The batteries provide a supply for the long hours when very little is required.
4. Applicability to the supply of motive power and other uses, besides light and heat.
5. Greater ease of measurement.
6. The regulation should be very good.
7. A battery current is less destructive to lamps.
8. From a consumer's point of view the supply made from accumulators *is the most* valuable.

And to make it clear that on the question of cost the evidence given was in favour of the direct supply, the following extracts are given from the evidence of witnesses *called in favour of the alternating system.*

Mr. A. Siemens.—Q. 3560. With regard to a united series of small stations, do you consider that to be one of the best solutions of lighting a town ?—Certainly, it is one of the best.

Q. 3568. From your experience, would not a small area be lighted as economically on a low-tension direct-current system as on the alternating-current system ?—Certainly, much cheaper.

Sir William Thomson.—Q. 3810. Assuming you have a very large area of supply, and a great number of lights to supply within that area, do not you consider the low-tension direct system more economical than an alternating system ?—If there is no point more than a quarter of a mile from the station, I should say so.

Q. 3811. Just about a quarter of a mile ?—I should say the direct system would be preferable.

For be it remembered that London is not a "scattered area," for which the alternating system may possibly be cheaper, but *a mass of densely populated small areas.* Thus the Board of Trade inspector, having the question properly left to him to report upon the systems, reports entirely in favour of the direct supply system.

And having, as it is submitted, most improperly left to him the question of provisional orders to be granted, treats with contempt the results found by himself, in order to exercise his evidently strong bias in favour of a particular company, and endeavours to salve his own conscience by the remark that "It may be predicted with tolerable certainty that whatever system proves itself to be best under all circumstances will eventually be adopted by all."

ELECTROLYSIS OF NICKEL SALTS.

BY ALEXANDER WATT.

(Continued from page 411.)

15. *Oxide of Nickel in Ammonia.*—A solution was prepared by digesting recently precipitated and moist hydrated oxide of nickel in strong liquid ammonia, and the resulting blue solution was afterwards moderately diluted with water. With the current from two small Daniell cells in series there was little or no metal deposited upon a brass cathode A third cell was therefore added, when a yellowish film of nickel formed upon both surfaces of a brass plate. There was no evolution of hydrogen at the cathode, but a copious liberation of gas at the anode, which electrode became coated with a brown-coloured film, and a green deposit also appeared on this plate at the surface just above the water-line. It thus appeared that two different substances had formed upon the positive electrode A green salt also formed in the solution, rendering it turbid.

16. *Nitrate of Nickel.*—A bath was prepared by dissolving nickel carbonate in one part nitric acid to two parts of water until a neutral solution was obtained. The resulting solution, after filtration, was electrolysed with the current from two Daniells in series, but no deposit of metal occurred. A third cell was then connected, but with a like result. No hydrogen was given off at the cathode, but a slight evolution of oxygen appeared at the positive electrode.

17. *Nitrates of Nickel and Ammonium.*—A solution of nitrate of ammonia was added, a little at a time, to the foregoing bath, and the same current employed, the object being to determine whether the ammonium salt would tend to assist the deposition of the metal. Such was not the case, however, for the cathode merely became discoloured, while a green deposit formed on its surface. In this case, as in the last, no hydrogen was liberated, but small bubbles of gas appeared at the anode.

18. *Sulphate of Nickel.*—A solution was prepared by dissolving one ounce of the salt in ten ounces of water, and the current from two cells at first tried ; but as the metal deposited but slowly, a third cell was put in series, when a clean brass plate readily became coated with nickel. The film, which was of a good colour, was not, however, so adherent as is the case with deposits from the double sulphates of nickel and ammonia.

19. *Ammonio-sulphate of Nickel.*—It was next determined to ascertain whether small and increasing additions of liquid ammonia to the sulphate solution would tend to increase the adhesion of the deposited metal and improve its character generally. The current from three cells, as before, was used, and a fresh plate immersed after each addition of the ammonia. When the first addition of ammonia had been given, it was noticed that the film appeared much brighter than that obtained with the nickel sulphate alone, and this characteristic was maintained until

Digitized by Google

the solution acquired a deep blue colour. On examining the anode, after several plates had been coated in the solution, it was found to be covered with a dark brown and almost black layer on both surfaces, which firmly adhered to the plate. It was also observed that a flocculent precipitate formed in the solution, and deposited at the bottom of the vessel.

20. *Sulphocyanide of Nickel.*—A strong solution of sulphocyanide of potassium was first prepared, to which was added, a little at a time, moist carbonate of nickel, each portion being allowed to dissolve before the next was added. The solution, which was nearly colourless, was then filtered and electrolysed with the current from three cells, when, after a few seconds, a dark steel-grey film of nickel formed upon both sides of a clean brass plate, the character of which did not appear to alter during half an hour's immersion. Gas was given off at both electrodes.

21. *Carbonate of Nickel in Binoxalate of Potassa.*—A hot solution of binoxalate of potash was first made, to which was gradually added moist carbonate of nickel, the mixture being well stirred after each addition, and the resulting solution, which was of a pale green colour, after being filtered, was electrolysed with the current from three cells. There was a brisk evolution of hydrogen, and a rather dark-coloured deposit of nickel slowly formed upon the brass cathode, but, however, only upon the front of the plate facing the anode.

22. *Chloride of Nickel.*—To form a bath of this salt, ¼-ounce of the dried salt was dissolved in half-a-pint of water, and the solution then filtered for use. With the current from two cells, a fairly prompt deposit of nickel took place upon a clean brass plate, but the colour was not quite so white as that obtained from some other salts of nickel. There was a rather brisk evolution of hydrogen. A better result was obtained with the current from three cells and a diminished anode surface. The metal was not so fully adherent as deposits from the double sulphates of nickel and ammonia.

23. *Chlorides of Nickel and Sodium.*—To the above solution was added about 10 per cent. of chloride of sodium, but this did not appear to present any advantage; in fact, the colour of deposits obtained in the modified bath was rather darker than in the former case, while the film was still less adherent.

24. *Sulphates of Nickel and Potassa.*—A bath was prepared by mixing solutions of the respective salts, and the resulting liquid was then electrolysed with the current from three cells. The solution proved an indifferent conductor, and the metal deposited very slowly. After an hour's immersion the negative plate was found to be coated with a black, granular, non-adherent film on its lower surface, while a narrow band of white metal appeared on the upper surface. When the plate was gently heated over a spirit-lamp, the black deposit rapidly split up into minute particles, which jumped off the plate with great velocity—due, probably, to the sudden expansion of absorbed hydrogen. The black deposit, which appeared to be nickel in a semi-metallic state, readily dissolved in nitric acid, forming a green solution.

25. *Sulphates of Nickel and Magnesium.*—To form a bath, solutions of the respective salts were mixed, and the current from two cells used. Under these conditions a brass cathode soon became coated with metal; but this, however, had a very decided yellow tint, and was also very dull. The anode on both sides was of a dark brown colour. A third cell was then connected, and a newly-cleaned plate immersed, which quickly became coated with nickel, but, as before, of a yellowish colour. The anode, however, now became much cleaner, only exhibiting a few dark brown patches on parts of the plate. The brass plate was then well scrubbed with powdered bathbrick and water, when the yellow tint referred to disappeared, and a fairly white film presented itself. In this solution there was little or no evolution of hydrogen. The anode surface immersed was about equal to that of the negative plate.

26. *Citrate of Nickel by Electrolysis.*—A strong solution of citric acid was first made, in which was placed a clean plate of rolled nickel, connected to the positive wire of a 3-cell Daniell battery, and a clean brass plate, attached to the negative, was immersed in the liquid at a distance of about 1in. from the anode. The object of this experiment was to ascertain whether the vegetable acid, under electrolysis, would dissolve the nickel freely; and the trial was so far satisfactory, that in about fifteen minutes after immersion the brass plate became coated with a film of nickel, while the solution also acquired a slightly green tinge, showing that the metal was dissolving with tolerable activity. It was observed that the metal deposited from this solution was very bright, and of a good white colour. On applying a steel burnisher to the nickeled surface after the plate had been fairly coated in the above solution it was found to be much softer than is usual with nickel; indeed, the deposited metal received a high polish under the burnisher, which would not have been possible with nickel deposited from the ordinary nickel-plating solutions. It should be mentioned that one of the objects of these experiments was to obtain, if possible, a solution-bath which would yield coatings of nickel sufficiently soft to undergo the ordinary operation of burnishing, which, it was believed, would be an advantage to the nickel-plater for certain classes of metal work. It must be mentioned, however, that although some solutions of nickel appear to yield softer deposits of the metal than others, the strength of the current also appears to affect the hardness of the deposited metal to some extent—a fact which I have also frequently noticed in the electro-deposition of silver, copper, and other metals.

27. *Citrates of Nickel and Ammonia.*—To a solution of citrate of nickel, prepared as described in the last paper,* was added one of citrate of ammonia, a rather strong bath being employed. With the current from two cells, deposition took place somewhat slowly; therefore, a third cell was at once attached, when the brass cathode quickly became coated with a film of nickel, which, however, was somewhat dull, and not very white. An addition of water was now given, and a fresh plate immersed, when the subsequent deposit was much improved both in colour and brightness. The electrode surfaces immersed in the bath were about equal, under which conditions deposition took place very promptly. The nickeled surface was afterwards tried with the steel burnisher, which readily rendered the surface bright without severe pressure of the tool, indicating that the metal, as in the case referred to, was rather softer than ordinary nickel deposits. On examining the anode, it was found to be partially coated with green oxide, which, however, soon redissolved in the solution when it was at rest. To prevent the formation of this deposit on the anode a slight excess of citric acid was added, which had the desired effect of keeping the anode clean.

28. *Nickel Carbonate in Cyanide of Potassium.*—A solution was prepared by adding recently precipitated and moist carbonate of nickel to a strong solution of cyanide of potassium, the liquid being afterwards filtered and moderately diluted with water. With the current from two cells no deposit was obtained, and only a slight and patchy film was received upon a brass plate upon the addition of another cell. There was much hydrogen given off, and the solution failing to yield a good film was abandoned.

29. *Carbonate of Nickel in Bisulphate of Potassa.*—This bath was prepared by digesting moist carbonate of nickel in a hot solution of bisulphate of potassa, in which the nickel salt readily dissolved. The solution was electrolysed with the current from one, two, and three cells respectively, but only an indifferent film could be obtained with the latter current. A white flocculent precipitate formed after a while, rendering the liquid turbid; the solution was therefore cast aside as of no special interest.

30. *Ammonio-Chloride of Nickel.*—To a solution of chloride of nickel was added strong liquid ammonia until the solution acquired a deep blue colour. The solution was then electrolysed with the current from two small Daniells, and a clean brass plate immersed, which quickly received a white coating of nickel on both of the immersed surfaces. With the current named it was only found necessary to expose an anode surface equal to about one-third of that of the negative electrode. There was very little hydrogen evolved, but a rather more copious elimination of gas at the anode. It was noticed that the deposited metal was very bright, and of a good white colour.

* *Electrical Engineer*, May 24, 1889.

Digitized by Google

31. *Ammonio-Nitrate of Nickel.*—To form a bath of this constitution, strong liquid ammonia was added to a solution of nitrate of nickel until the precipitate at first formed became redissolved. The current from two cells was used, and a brass plate received a film of nickel of a rather dark colour on both sides soon after immersion, the electrode surfaces being about equal. On examining the anode, after half an hour's immersion of the plates, it was found to be stained a deep brown, or almost a black colour.

32. *Ammonio-Acetate of Nickel.*—To a strong solution of acetate of nickel was added liquid ammonia until the solution acquired a deep blue colour. With the current from two cells a tolerably quick deposit of nickel was obtained upon both sides of a brass plate, which was of good colour, bright, and very adherent. To obtain the deposit at a fair rate of speed with the above current, a small surface of anode only was found necessary.

33. *Ammonoi-Citrate of Nickel.*—Strong liquid ammonia was added to a solution of citrate of nickel until a deep blue solution was obtained, which was afterwards electrolysed with the current from two cells. On immersing a clean brass plate it quickly became coated with a bright and white film of nickel, which adhered very firmly to the plate. As in the previous case, a very small anode surface was immersed—about one-third that of the negative electrode. The anode kept perfectly clean during the electroytic action.

34. *Ammonio-Carbonate of Nickel.*—The solution for this experiment was prepared by dissolving recently precipitated and moist carbonate of nickel in a strong solution of sesquicarbonate of ammonia, and the resulting liquid was electrolysed with the current from two cells. On immersing a clean brass plate it soon became coated with nickel, but as the colour of the film was rather dark, a third cell was connected, but not, however, with any apparent advantage, since the deposit still lacked whiteness. Moreover, the deposited metal from this solution was less bright than that obtained from the preceding bath.

35. *Carbonate of Nickel in Ammonia.*—A quantity of moist carbonate of nickel was next dissolved in strong liquid ammonia, and the resulting pale blue solution, after being moderately diluted, was tried with the current from two cells, but as deposition took place somewhat slowly, a third cell was connected. On immersing a freshly prepared plate in this bath, with small anode surface, a very bright film of a good white colour was speedily obtained, and even after an hour's immersion the deposited metal still retained its brightness.

(To be continued.)

ELECTRIC LIGHTING OF LONDON.

Prof. S. Thompson writes as follows to the *Times:*

"I have waited, expecting some expression from other pens of the feelings of astonishment and regret which the report to the Board of Trade on the subject of electric lighting has aroused in the breasts of some of those who have been, during the past ten years, most active in promoting this branch of scientific industry. That an enquiry, apparently so impartial and disinterested, should have resulted in conclusions so illogical, so obviously one-sided, and so inimical to the interests of a large section of the community, is, indeed, to be deplored. It is with the hope that some amendment or reconsideration may be effected before Parliamentary sanction is asked for the details of the scheme that I venture to address you. The report of Major Marindin, endorsed by the Board of Trade's adviser, Major Cardew, adopts the principle of the allocation of definite districts to definite companies, and sanctions the principle, doubtless in the interests of the public at large, of admitting more than one company into one district. The ostensible reason for this admission of the principle of competition is not, however, that of benefit to the public; the sole and only reason offered by the Board of Trade is much more specific. There are two general methods of electric supply—one known as the continuous current system, the other the alternating current system, the latter differing from the former in that the electric currents, instead of flowing steadily and continuously in one direction through the conducting wires, are incessantly oscillating in alternate directions. Each system has its advantages in particular cases, and certain companies have made themselves champions of the rival systems. The sole reason now alleged by the Board of Trade for admitting to one district two competing companies is that while the continuous current can be used not only for lighting lamps, but also for driving electric motors, so making the system of double use for the distribution of power as well as of light, hitherto it has been found impossible to use the alternate current to operate electric motors. Admitting that this important fact, though only one of a number of important facts, is entirely true, and that it affords a justification to the principle of competition between the two systems, what, I would ask, is the fair and natural inference to be drawn? What would, in face of this circumstance, be the procedure which should be fair to the companies who respectively apply for rights of supply in the districts and to the public who are the consumers? Because an alternating current company cannot supply the public with electric power as well as light, is that any reason for excluding from any district a company that can? Is it fair or right that in the only districts where absolute monopolies are granted, they should be granted to alternate-current systems? Is it fair or right that in districts which do not want an alternate current, but do want a continuous-current supply, that which they need and desire should be refused admission, and that which is incompetent to serve them should be allotted a monopoly? That is, however, exactly what the Board of Trade proposes; they propose to hand over nine-tenths of the allotted districts to the exclusive control of either the Metropolitan Electric Company or of the London Electric Supply Corporation, both these companies supplying only alternating currents in their respective districts.

"I pass to another point, which has been very conveniently slurred over in the Board of Trade report—namely, the uncertainty which attends alternate current supplies, arising from the impossibility of using accumulators with alternating currents. The alternating current system has no storage to draw upon; it lives from hand to mouth, as would a system of gas distribution in the absence of gasometers. A mere derangement of an engine or a boiler may, in the absence of storage, plunge a whole district into darkness. Is this, I would ask, any justification for the action of the Board of Trade in its determination to disallow over the greater part of the metropolis the entrance of any competition by companies that can use storage, and to hand over nine-tenths of the allotted areas to the monopoly of alternating current companies that do not and cannot use a storage system? Further, does it not seem monstrous that the whole of the proposals of the Electric Power Storage Company, one of the competing applicants, who asked not for a monopoly for themselves, but for fair field to compete with the alternating current companies, should by the Board of Trade's action be ruled out on a mere technicality, which could have been set right at Somerset House for a few half-crowns? This is not the kind of decision which the public expects from a semi-scientific tribunal, before which a system ought to be considered on its merits.

"The letter of Mr. Calcraft's which accompanies Major Marindin's report and promulgates the Board of Trade's decisions is curiously contradictory. He first announces that competing powers to two companies are given only in the following districts: St. George's, Hanover-square, a small portion of Lambeth, and a small portion of St. Martin-in-the-Fields. Further perusal of the letter shows, however, that this is not so, because by allotting powers in Chelsea and in St. James's, Westminster, to the London Electric Supply Corporation, this company, which is one of the two alternating companies, that proposed between them to cover nearly all London, is here admitted to districts where there already are other companies satisfactorily at work. In fact, Mr. Calcraft seems strictly to have adopted the notorious creed of the promoters of the London Electric Supply Corporation—namely, so long as they gain a footing in a parish, it matters not having a competitor; in so doing he not merely abandons, but deliberately inverts

Digitized by Google

the sound principle laid down in his own report in 1883—that so long as a company in a district does its duty to the public, so long a competitor is not to be admitted. To the new principle of competition now announced he makes exceptions. Indeed, the cases of exception are more numerous than the cases in which the alleged principle is observed. For example, in Kensington parish, where a storage supply already exists, the district is to be divided between the existing and a rival alternating current system, but each is to be confined to a special sub-district, so that there is no competition; in the City, there are to be two companies, *both alternating*, and each is to have a definite sub-district Again, wherever the vestry in a district objects to competition, one company only will be admitted. The letter of Mr. Calcraft is effectual indeed in reducing the alleged principle of competition (in the interest of the public) between alternating and continuous supply to a mere farce. His principle of competition appears to be put in force only where it can serve the purpose of either of the two great alternating current companies—the London Electric Supply Corporation and the Metropolitan Electric Company; and it is dispensed with wherever it is convenient to give those companies a monopoly over their competitors. Even the meaning of the scientific evidence taken at the inquiry appears to have been misunderstood; for, from the body of the report, it is said: 'Of the scientific witnesses called as to the relative merits of the two systems of supply, the great majority were in favour of the alternating transformer system *for large areas*' (the italics are mine). This is a distinct misinterpretation of the evidence, which was throughout consistent in the expression of opinion that the alternating transformer was preferable not for large areas, but for what was called *scattered* areas—*i.e.*, districts in which there was a small number of consumers to be supplied in proportion to the area. It was not by any means the opinion expressed by the scientific witnesses that *dense* areas, whether large or small, were better supplied by transformers than by direct currents. The substitution of the word 'large' for the truer term 'sparsely populated,' entirely alters the drift of the evidence.

"As this letter has already extended to so great length, I forbear to add further criticisms. Doubtless such will be forthcoming from other quarters. I conclude for the present by repeating my protest against the illogical, lame, and unfair proposals which have been put forward in the name of the Board of Trade, and to express my hope that the London County Council will not sanction them until they have been so reconstructed as to remove their most objectionable features."

MESSRS. CROMPTON AND CO.

Last Friday—as a note in our issue of May 31 may have advised our readers—an exceedingly pleasant evening was spent at the Café Royal, in Regent-street, the entertainers being Messrs. Crompton and Co., and the *raison d'être* of the gathering to bring together the past and present pupils of the firm and some of the friends of the firm. Mr. Crompton, in the absence of the chairman of the company through illness, occupied the chair, and this was as it should be, for the visitors towards the end of the evening found that the day was the anniversary of the natal day of the chairman. It requires the lighter view of a society journal rather than the sober-sidedness of a technical paper to do justice to a gathering of this kind. The conception of such a meeting was a happy thought, as characteristic reminiscences hang around the works concerning those pupils who have long since left to occupy their energies in the wider sphere of industrial strife, and the present generation likes to be made acquainted with that that is gone. Many of Messrs. Crompton's old pupils are making a name for themselves in the world; many of the present pupils will be nerved to plod merrily along, having the success of their predecessors in view, and knowing that usually what man has done man can do again. We have long held the best way to win a place in the ranks of the electrical industry is to go through the works; and if to this is added theoretical training, the ideal state of apprenticeship is almost reached. Messrs. Crompton may claim to be one of the oldest, if not the oldest, of the firms who have attempted properly to train pupils for electrical engineering work. The firm has also from time to time inaugurated series of lectures on theory by such able exponents of the science as Prof. Fleming. But this is passing from the special to the general. Our immediate text is Friday's gathering, and if friendly faces and friendly expressions indicate the success of a firm, then Crompton and Co. must take a very high position indeed. The number of friends present was large, and from the Mayor of Chelmsford, who had just signed the contract for lighting Chelmsford, through the words of all other speakers, the gamut of praise was consistently sung. The evening's proceedings were enlivened with some excellent music, Mr. Gatehouse on the violin discoursing sweet sounds, while various songs contributed to the harmony. Genial Mr. Preece was in his happiest vein, and the scientific accuracy with which he proved the ancient invention of Daniell's cell, as well as of some other supposed modern inventions, will not soon be forgotten by those who listened, heard, and applauded Mr. Williams also let the cat out of the bag as to certain undetected ghosts which used to haunt Chelmsford, bringing the remark from the Mayor that he presided at the court and should certainly exert his authority if aught contrary to law was detected. We might, perhaps, say that the animal spirits of Chelmsford sometimes take another course than ghostly action, as some of our country contemporaries can testify.

The pleasantness of the evening was enhanced by a gentleman—not down in the regular programme to speak—asking permission to give his testimony of Messrs. Crompton and Co. from a purely business point of view. The testimony was exceedingly good, the gentleman having obtained from the firm something out of the common way with great dispatch, and having been greatly pleased with the obliging manner in which his enquiries were met.

We cannot conclude this brief reference to a delightful evening without mention of a question which affects the well-being of the technical press. The unanimity of the speakers on this point was conspicuous—that Messrs. Crompton and Co. were always more than ready to give all possible information upon their work and manufactures, making it a pleasanter task to meet than it was to obtain similar information from firms whose efforts were seemingly directed to keep secret what really was no secret, and what really could not be kept secret.

The proceedings ended by a hearty vote of thanks to the chairman, who cannot but feel gratified at the great success of these annual meetings.

ELECTRIC MINERS' SAFETY LAMPS.

To the Editor of the Electrical Engineer.

Sir,—Mr. Niblett has asked me a question which I fear is not easy to answer. The position of the incandescent lamp itself, in the miners' portable electric lamp, is a matter that will really only be decided after extended practical use. At present, all that we can do is to indicate the position which, so far as one can see, offers fewest disadvantages. This, I think, is the position which Mr. Pitkin and Mr. Swan have chosen for their lamp.

On the top, the light is in one's eyes, you do not get the same amount of light in any given direction as when the rays are concentrated, and you have no light on the ground immediately at your feet, underneath the bottom of the case. You have no light upwards, and the arrangement presents certain mechanical and electrical difficulties. On the side, you have the advantage of being able to concentrate the rays from your lamp, so as to obtain a higher degree of illumination in any given direction, while, provided the apparatus be properly constructed, you can turn the rays of the lamp upon any object in any position.

The connections to the lamp are more easily arranged when it is placed on the top, but there are no serious difficulties involved in placing it on the side.

One requirement that Mr. Niblett has named is, I think, hardly necessary. It will, perhaps, be better for the lamp to be strong; but no collier makes a seat of the existing Davy lamp.—Yours, etc., Sydney F. Walker.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

A communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed " Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

Although the Paris Exhibition is open, the major portion of the exhibits are in so backward a state that any systematic description is almost impossible at present, so we shall wait a short time till the chaos of packing cases becomes a neat arrangement of exhibits. It is needless to tell our readers that—so far as our description of the electrical exhibits is concerned—our attention will, in the first place, be directed to the interests of English and American exhibitors. A special edition of this paper, with the report of the exhibition in two languages—English and French—will be obtainable in the Exhibition.

THE ELECTRIC CONSTRUCTION CORPORATION.

The prospectus of this company has been issued, and although it does not completely follow the lines indicated by us last week our forecast was, broadly speaking, correct. The interests amalgamated by this combination are connected more directly with accumulators and traction. Two good businesses are absorbed, and will form the nucleus of what should be a good manufacturing concern. The Electrical Power and Storage Company had a unique position. Through evil report and through good report it pursued the even tenour of its way, and to that company, in conjunction with Elwell-Parker, the accumulator business owes its position to-day. The Electrical Power and Storage Company and Elwell-Parker combined form a substantial source of action, but besides these the promoters have brought into the net the Julien and the Sprague interests, the latter of which has been particularly successful in the States. The position of a technical paper in the criticism of this new company is rendered exceedingly difficult, because, as a combination, the company is sound, and under the proposed management it should be a great success. Had this combination been brought about without any company-mongering proclivities, it would have been impossible to do aught but praise the action. As it is, we must utter our emphatic protest against the method and results of promotion. Unless we are greatly mistaken, the workers—that is, those who have to get the trade and earn the dividends—do not care to be handicapped with huge sums gone as promotion-money. A millstone of at least a hundred thousand pounds has in this case been hanged around their necks. While, then, we are in thorough accord with the combination in its working capacity, we are wholly antagonistic to the finance of its promoters. Let us assume that the promoter is worthy of his hire, and that his business is to get all he can ; our business is to spoil his little game if we believe the public are being fleeced unnecessarily. In these cases the public have to pay the piper, but it is seldom that they can call the tune.

The prospectus, p. 10, refers to a number of contracts made between various firms and gentlemen on the one part and Mr. Herbert Edward Tarver on the other part, *which can be inspected* ; and on p. 11 refers to numerous contracts made between the said Mr. H. E. Tarver and others, which *cannot be seen.* In other words, a Tarver or any other name would act just as well. He is not the real negotiator, he does not take the plunder, though he is put forward and much made of his "arduous" labours. Well, over a hundred thousand pounds will console most men for some pretty difficult work, far more difficult, we should imagine, than anything done in connection with this scheme. We speak of a

Digitized by Google

hundred thousand pounds advisedly, because, according to the "to be seen" contracts, Mr. Tarver pays in cash and shares £288,000 for something for which he gets £397,300 and certain interest. Now the difference between these two amounts is £109,300, which is paid by the company to somebody for something. We can find the ostensible somebody, but is the work done by the somebody worth £109,300. Who is Mr. Tarver? Singular to say, his name does not figure among the list of founders, so that if there be any reality in Mr. Tarver he has no great affection for the child he has created. Dean Swift may have had a figure-head company-monger in mind when he wrote: "How fading and insipid do all objects accost us that are not conveyed in the vehicle of delusion! How shrunk is everything as it appears in the glass of Nature, so that if it were not for the assistance of artificial mediums, false lights, refracted angles, varnish and tinsel, there would be a mighty level in. . ." Is Mr. Tarver an artificial medium or a vehicle of delusion. If so, where and who is the real Simon Pure? We can make a very shrewd guess, and if there were any righteous laws in company promotion we could soon get at the truth by inspecting the now "not to be seen" contracts.

It has been suggested to us that the working capital remaining after the payment of the £397,300, will be insufficient for the requirements of the company. Those who hold this opinion can hardly have considered the matter fully, and saying this, it is hardly necessary to give our opinion that the working capital will, for a long time to come, perhaps always, be amply sufficient. If only half of what is going to Mr. Tarver and Co. had gone to increase working balance, no doubt as to its sufficiency would have arisen.

After writing thus far we followed the Addisonian practice and dreamed a dream. In that dream we seemed acting with company promoters, whose *modus operandi* was to lay hold of something good, to manipulate matters among a clique so as to get a good big sum, promotion money, underwrite half the share capital, divide the founders' shares and promotion money *pro rata*, deduct a certain part of the promotion money to rig the Stock Exchange and nobble the press. In a particular concern one masterful man would have 2,000 ordinary shares of £5 each. From the promotion money he got £8,000. By manipulating the market the shares were rushed to £2 premium. He sold out 1,500 shares, making a profit of £3,000, or getting a total of £11,000, out of which he paid for 500 shares £2,500, making a clear gain of £8,500, or rather of £7,700, for he had to contribute £800 towards preliminary and other expenses.

Then came the awaking, and behold we applied the dream figures to the actual case before us. We assume that £75,000 is all that Tarver and Co. realise nett profit. Each founder's share then gets £750 of this, so that if the shares reach a premium of £1, and 200 out of the 250 ordinary shares which carry one founder's share are sold, the money received will be 750 + 200, or £950, while the cost of the remaining 50 shares will be £250, leaving a nett gain of £700. If he unloads only 100 shares, he will get his 150 remaining shares for nothing, and be £100 in pocket. Take as a specific example the largest amount underwritten—viz., 1,500 shares. According to our assumption, this carries £4,500 of the promotion money. If the shares go to a premium of £1, and 1,000 are sold, the total gain is £5,500, out of which £2,500 is paid for the remaining 500 shares, the underwriter getting £3,000 nett, or, in other words, has 500 shares for nothing and pockets £3,000 because he was one of the promoters.

No doubt the financial promoters will give us their approbation for our humble efforts to unravel this riddle of how it is done. We shall receive their good opinion with gratitude, and to the utmost of our poor capacity shall take hold of all opportunities to return the obligation.

THE TELEPHONE COMPANIES.

In our issue of April 12th we discussed the proposed amalgamation of the telephone companies. Since then other incidents have arisen which have somewhat altered the position of affairs. The Government practically vetoed the original scheme, and another has been proposed in its place. The telephone companies seem determined to force the hands of the Government, though we suspect the final result will be that the shareholders would have preferred to see their directors banished to Siberia rather than placed in the position they will be.

Firstly, let it be clearly understood that the telephonic wire-pullers are looking after number one. They will make money whatever happens to the shareholders. They are behind the scenes, can sell or buy with perfect safety, and most certainly they will be found unloaded when the crash comes. There are ominous signs that the Government will not long delay action. The reply of Mr. Raikes to Mr. Chamberlain and his letter to the telephone companies are proofs of this. The telephone companies, too, recognise the fact, and admit the present position to be a fair stand-up fight. At least we can find no other interpretation to Mr. Brand's views, given at the meeting on Tuesday, expressed as follows: "The Postmaster-General, who, in the pursuit of the duties of his office, was a very keen trader, would certainly be more able to bring his devices to pass if he had to deal with

Digitized by Google

the various companies singly, than if he had to deal with one great company, strong in unity, in financial position, and with one strong executive body." An attempt was made to qualify these views in the succeeding part of the speech, but they cannot be qualified. Put into plain English, the words mean "We amalgamate the better to fight." Now, whatever happens, the shareholders will have justice, but if Messrs. Brand and Co. imagine for a moment they are going to force one stiver more from the public purse than they are justly entitled to, they are greatly mistaken. Their management of the telephone ring has been patent for years. The subscribers have not been thought of. The management cannot justify any claim to vested interests; they have none. The lines would be a disgrace to a country blacksmith, in that it is only by chance you can get clear intonation in speaking. More often you have to guess half what your correspondent is saying than to be certain on the subject. That the difficulties can be met and overcome is an undeniable fact, for they are avoided in towns other than London. The major portion of the subscribers would welcome any change that would bring about improvement, and as the Government officials and other companies have shown what really can be done in the North and in the West, the sooner the present incompetent London management becomes a thing of the past the better. Unfortunately, the United Company dominates, more or less, all the other companies by its holding of shares, and we contend it has all along been a drag upon the true development of the telephonic industry. More than once we have stated the true policy for its shareholders. The work should have been done in the best possible manner, the interests of subscribers consulted, the price diminished and the number of subscribers increased to the utmost extent. As it is, the work will mostly have to be pulled down and replaced, the cross talking stopped, clearness of intonation obtained, and the cost lowered till a reasonable amount is charged. We are not the exponents of the Government policy, yet we give an emphatic denial to Mr. Brand's statement that every obstacle had been put in the way of the company. He is absolutely wrong. Telephony is a branch of telegraphy, and why the Government is to forego its claims in order to benefit a set of private individuals, why the public is to lose its just reward to benefit them, is beyond comprehension. Government officials are kicked much more often than praised, and it will be well occasionally to admit that their efforts are calculated to benefit the general public, and not to gain a fleeting popularity by pandering to company-mongers.

Biographical.—An interesting life, with portrait, of the Secretary of the Society of Arts, Mr. H. Trueman Woods, appears in the *Mining Journal* for June 1, 1889.

POCKET AMMETERS AND VOLTMETERS.

The pocket-measuring instruments illustrated herewith are made as ammeters or as voltmeters, and are likely to prove exceedingly useful to electrical engineers who require a thoroughly portable and neat little pocket instrument. The illustrations show the instrument in full size. They are made in the form of a watch, nickel-plated outside

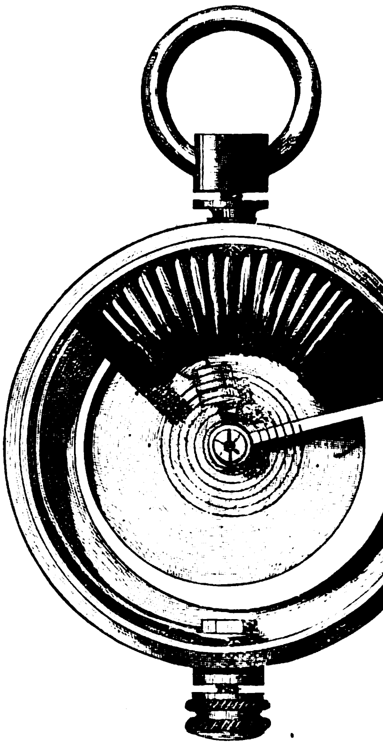

Fig. 1.

Fig. 1 shows the works. A solenoid is arranged with a tapered curved core, which is sucked therein under the action of the current. The core is controlled by a long spiral watch spring, made of a special material, which is selected to withstand changes of temperature. Fig. 2

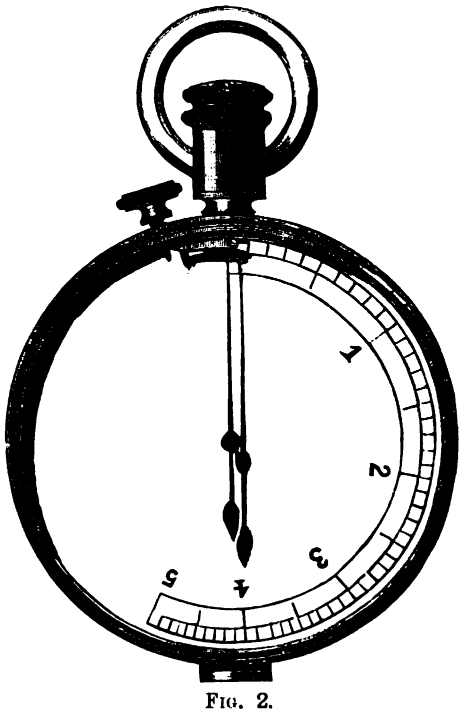

Fig. 2.

shows the instrument in front view, in this case reading from one to five amperes. They are also made to read from 10 to 50 amperes. The voltmeters are made to read from one to five volts, 10 to 50 volts, and 20 to 100 volts. The deflection for one volt or one ampere is 20deg., so that great accuracy can be obtained in the measurement of small currents. The connections are made at the top

and bottom of the instrument; the screw shown within the ring in Fig. 2 unscrews and fits into the threaded hole at the bottom. A little screw, to which a small finger is attached, clips the needle and keeps it from swinging loose when not in use. The pivots supporting the hands work in jewelled holes. We have inspected these instruments, which are made by Messrs. Mayfield and Co., Limited, and they seem to be very neat and thoroughly serviceable for the purpose intended.

JAPAN AND CHINA.

The extremely hazy ideas which possessed the minds of our people with respect to these two countries up to a comparatively recent period have not been entirely eradicated, for we meet with persons of average intelligence who still regard their peoples as bearing, in some undefined way, close relationship, whereas no comparison can really be instituted. This is especially evident when we take into consideration the progress made by Japan in public works in the past twenty years, while China has practically been inactive. All that Japan possesses in common with China now are those square hieroglyphics which do duty as letters in books and manuscripts, and even here Japan has left her unwieldy neighbour far behind in the race, for she has an abbreviated character of her own, forming a syllabary capable of expressing every sound of the language in 45 signs, in lieu of the enormous total of fifty thousand or more (some seven thousand of which are in regular the daily use), comprised in Chinese dictionaries. In fact, the Japanese tongue has an alphabet, but the Chinese has none, and the Japanese could do without the square hieroglyphic entirely were it not for their ancient literature, which has been derived principally from Chinese sources any time within the last fifteen centuries. In their manners and customs, modes of thought, enterprise and pluck, their marvellous adaptability to new surroundings, and, not least, their thoroughly martial spirit, the people ruled by the Mikado differ from the tortoise-like subjects of the Court of Pekin, as light from darkness.

Japan is building her own railways and telegraphs, and undertaking nearly all her public works by native engineers and workmen. Already the telegraph mileage measures well into five figures, and the railways in operation or in course of construction extend over 2,000 miles.

The Chinese are at last moving, and if no misfortune attends the railway now being laid, they may in reality carry the line up to the gates of Pekin, from its ports of Taku and Tientsin, and the mines of Kai-ping. But a collision or other accident, with the slaughter of a mandarin or two, would inevitably check farther progress.

Electric lighting, after being a failure for a time, is gaining ground in both China and Japan, but the field is a wide one, and there is room for much more enterprise on the part of our manufacturers than they have hitherto shown. Continental firms have had orders placed with them which ought to have come to us had our people been sufficiently wideawake.

It is not too late to remedy this if what we hear be true, that a great impetus is to be given to electric work of all kinds in both countries by native guilds. Electric lighting, telephones, telpherage, all will have their share, and, admitting that the clever Japanese turn out splendid instruments and fittings of all kinds, they are still indebted to Europe for wire for both open and covered work. They cannot draw iron wire properly yet, or make good cables, though they do nearly everything else. One or two of our firms have travelling representatives out in the Far East, but there is a vast amount of work in contemplation, and a grand opening for capital and energy. The tendency out there now is to raise the requisite funds and undertake this class of work by local companies, all of which ought thus to be good customers if well looked after. The Government is gradually retiring from what may be termed commercial undertakings, content to merely maintain a watchful eye over them, whilst enriching its exchequer with the fees on licenses.

It well known that our traders in the Far East are somewhat severely handicapped in the struggle for business in competition with those of Continental nations. Our consuls and other officials are prohibited—and rightly so from our point of view—from engaging in any trade or occupation other than that which strictly appertains to the discharge of the consular function. But with most other European nations this is not the rule, and the consul is usually himself a trader, and may reasonably be held to derive some advantage from his official rank in dealing with the native merchants. For a proof of this one has only to observe the eagerness with which the office is undertaken when a vacancy occurs. There is no way of fairly balancing this unequal competition; but something may be done by the establishment of agents possessing local knowledge and speaking the language.

To sum up, there is an excellent opportunity now for extending our business relations with both Japan and China, but we seem to need something more than the mere despatch of trade reports and circulars to secure the business. It requires pushing on the spot. Yokohama was, some time since, partially lighted electrically by an English merchant who we believe is a chemist, and who, we may suppose, brought no special skill to bear upon the work. He possessed, however, the very serviceable qualifications of energy and capital.

It is very evident to anyone who has been out there that a large amount of business could be at once procured if British merchants would properly bestir themselves.

THE EFFICIENCY OF METHODS OF ARTIFICIAL ILLUMINATION.*

BY EDWARD L. NICHOLS, PROF. OF PHYSICS IN CORNELL UNIVERSITY.

(*Concluded from page 433.*)

An Edison lamp, similar to that which had been used as a standard in our previous measurements, was subjected to spectro-photometric analysis by Mr. Franklin and myself at four candles, 10 candles, 16 candles, 22 candles, and 28 candles successively. The results obtained are shown in Fig. 9.

The spectrum of the lamp at 16 candles is taken as of unit brightness throughout, and the other curves show the amount of light of each wave-length emitted by the lamp in the above-mentioned states of incandescence. Intensities, in every case, are referred to the light of corresponding wave-length, given by the same lamp at 16 candles, as unity.

At the red end of the spectrum the intensity increases more slowly than candle-power, at the violet end more rapidly. There exists an intermediate wave-length, for which the brightness is proportional to the candle-power. The vertical line in the diagram shows the portion of the spectrum for which this holds true, a point in the yellow at wave-length 6,000.

If we suppose the same measurements executed upon a set of lamps in every respect similar to the one in question, excepting that their radiating surfaces are of such size that they give 16 candles, as indicated by the Bunsen photometer when the degree of incandescence corresponds respectively to that at which the lamp actually measured emitted at 4, 10, 16, 22, and 28 candles, there would result a set of curves of the same general character as those in Fig. 12. At wave-length 6,000, these curves would have a common value, and they would serve to indicate both the quantity and quality of the variation of the carbon filament as a function of the incandescence, candle-power remaining constant. The form of these curves is shown in Fig. 10. They afford us data for discussion of the candle as a standard of illumination which could not be obtained in any other way. They show the relative distribution of energy in the spectrum of five lamps, which, according to the indications of the Bunsen photometer, are of equal brightness, but which differ both in the quality and in the total energy of their luminous radiation. Their efficiency expressed in terms of the candle-power produced per watt expressed

* Paper read before the American Institute of Electrical Engineers, March 12, 1889.

Digitized by Google

in the lamp, rises rapidly as the incandescence increases. For lamps of the type upon which these measurements were made, for instance, the relative efficiency referred in each case to that of the lamp, the incandescence of which corresponds to that of an Edison lamp at 16 candles, is given in the column headed $\frac{\text{Candle-power}}{\text{Watts.}}$ in table VII.

TABLE VII.

State of incandescence equivalent to that of an Edison 16 c.p. lamp giving—	Relative efficiency referred to that of a 16 candle lamp as unity.	
	Candle-power / Watts.	Luminous radiation / Total radiation.
(1) 4 candles	·394	·211
(2) 10 candles	·729	·632
(3) 16 candles	1·000	1·000
(4) 22 candles	1·218	1·368
(5) 28 candles	1·391	1·589

If, however, we retain as the measure of efficiency the ratio, $\frac{\text{luminous radiation}}{\text{total radiation}}$, we can deduce from these curves values coinciding with those reached by the method of the thermopile and alum cell. To this end we must know the above-mentioned ratio for some one candle-power and the number of watts necessary to the production of each state of incandescence for which the computation is to be made.

The relative efficiency can then be calculated from the areas enclosed by the respective curves. Were the candle-power proportional to the energy of luminous radiation, the values thus obtained would be identical with relative efficiency determined from the relation of candle-power to watts. The relative efficiency thus computed (see table VII.) does not coincide with that obtained from the ratio of watts to candle-power, however, for the reason that the various rays which make up the visible spectrum do not enter into the production of candle-power in proportion to their energy. The most important wave-lengths, so far as light-giving power is concerned, are those which form the yellow of the spectrum, and the relative luminosity falls off rapidly both toward the red and the violet. The longer wave-lengths have, however, much more influence upon candle-power than the more refrangible rays, as will be seen by an inspection of the curves, the relative falling off of the red end of the spectrum being compensated by larger and larger accessions in the blue and violet as the state of incandescence increases.

Luminosity is the factor which we must take into account in seeking a complete expression for the efficiency of any source of illumination, and the method to be pursued in the determination of the luminosity must depend upon the use to which the light is to be applied. If we estimate light by its power of bringing out the colours of natural objects, the value which we place upon the blue and violet rays must be very different from that which would be ascribed to them if we consider merely its power of illumination as applied to black and white. In a picture gallery, for instance, or upon the stage, the value of an illuminant increases with the temperature of the incandescent material out of all proportion to the candle-power, whereas candle-power affords an excellent measure of the light to be used in a reading-room.

A number of determinations of the luminosity of artificial light have been made. In the earliest of these by Vierordt* the amount of white light which may be mixed with each colour of the spectrum, without producing an appreciable change of tint, was taken as the measure of the luminosity of that colour. The result is shown graphically in Fig. 11. The curve indicates the light-giving power of each wave-length, estimated in the above manner. The source of light experimented upon was a petroleum flame. The vertical line indicates the region of the spectrum within which — according to the measurements of the quality of light of the incandescent lamp already described —the increase in the brightness of the spectrum is proportional to the candle power. This region corresponds very nearly with that of maximum luminosity of the spectrum.

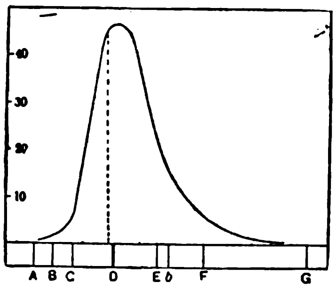

FIG. 11.

The luminosity of the blue and violet rays is so very small that in the production of candle-power the influence of the very rapid growth of this end of the spectrum with increasing temperature of the lamp is scarcely appreciable. If we estimate the light-giving value of the different portions of the spectrum by means of the facility with which we can distinguish black characters upon a white ground, the importance of the more refrangible rays is still farther diminished. Thus Mace de Lepinary and Nicati* have shown that if yellow and blue light, estimated to be of equal brightness by photometric means, are of such intensity that one can clearly distinguish a printed page when illuminated by the yellow, the same page will be entirely illegible when the blue light alone falls upon it. These observers conclude, indeed, "That mere distinguishing of objects is due almost exclusively to the illumination produced by the less refrangible half of the normal spectrum," so that at equal brilliancy "the superiority of yellow sources of light (luminous gas flames, incandescent lamps) over sources richer in blue rays (light of the electric arc) is incontestable." "The only real advantage," they add, "upon the side of the light from the electric arc is when one desires to rehabilitate objects more nearly in the hues which they present in the light of day." This single advantage is one which it is impossible to take due account of, numerically, in an estimate of the efficiency of artificial illumination. It is nevertheless a most important factor in determining the adaptability of a light to nearly all the purposes of everyday life.

Otto Schumann,† to whom we owe a most exhaustive study of the light of the incandescent lamp, has determined the luminosity of several types of such lamps at various stages of incandescence. His results, in so far as they apply to a 16-c.p. Edison lamp, are given in table VIII.

TABLE VIII.

Luminosity of an Edison lamp at various stages of incandescence, according to Otto Schumann.

Amperes.	Volts.	Watts.	Luminosity of various regions of the spectrum.						
			Red λ= 676	Or'nge λ 656	Yellow λ 615	Green λ 557	Blue λ 487	Indig λ 464	Violet λ 439
0·625	87·3	54·6	1·18	4·64	—	20·14	0·64	0·11	—
·678	90·4	61·3	1·68	6·66	—	30·35	1·05	0·20	—
·727	94·7	68·8	2·24	9·34	53·11	50·05	1·71	0·34	—
·748	97·4	72·9	2·59	10·92	63·28	62·23	2·28	0·47	—
·823	105·0	86·4	4·06	17·14	99·22	104·3	4·09	0·88	—
·944	112·9	106·7	6·97	28·85	163·0	189·1	7·88	1·75	—
1·009	117·6	118·6	8·74	37·14	222·6	255·7	11·62	2·71	0·42
1·035	120·4	124·7	9·36	41·67	263·3	317·7	16·04	3·79	0·60
1·099	124·5	136·4	11·43	52·36	345·2	472·2	26·24	6·53	1·04

I have made these values of Schumann's the basis of a set of curves, by means of which the variation in luminosity, with total energy in watts, is exhibited (see Fig. 12). It will be seen that the position of the maximum moves slightly toward the violet as the brightness of the lamp increases. This tendency is very slight within the range

* C. Vierordt, *Annalen der Physik und Chemie*, Bd. 137, p. 200.

Digitized by Google

of temperatures reached by the incandescent lamp. In the arc light we should find the displacement more marked, but in the case of sunlight, in which, as we have seen, the shorter wave-lengths are in such preponderance, the movement of the maximum is inconsiderable. The curves shown in Fig. 13 are taken from the investigation by Crova, who has determined the distribution of luminosities in the spectrum of sunlight, and of the flame of a petroleum lamp. The maximum in sunlight is at $\lambda = 582$, that of the petroleum $\lambda = 592$. Nearly all sources of illumination will be found to have a maximum lying between these two wave-lengths.

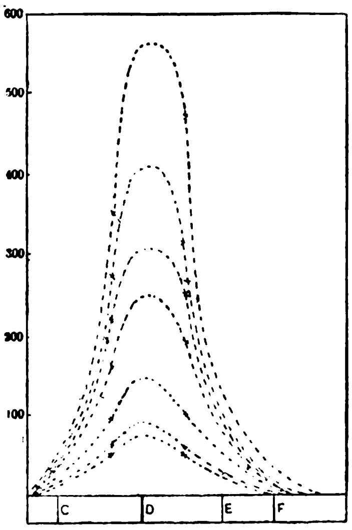

Fig. 12.

A comparison of the total luminosity of the incandescent lamp with its candle-power shows that the former increases with the energy of the lamp more rapidly than the latter, although the discrepancy is not so marked as in the comparison of efficiency of candle-power with that of luminous radiation.

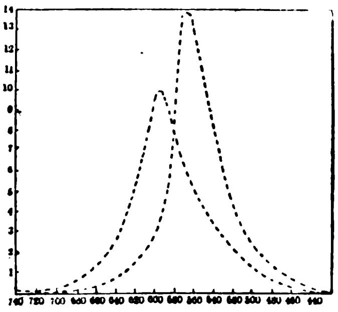

Fig. 13.

The following table, obtained by the summation of the luminosity curves, shows the relation between candle-power and total luminosity, in the case of the lamp studied by Schumann.

Table IX.

Candle-power and total luminosity of the incandescent lamp.

Watts.	Candle-power.	Total luminosity.
54·6	—	4·11
61·3	—	6·31
68·8	10·12	10·20
72·9	12·05	12·58
86·4	18·80	20·64
106·7	31·60	36·80
118·6	41·44	49·77
124·7	50·16	60·85
136·4	64·15	—

Plainly, then, candle-power does not afford a measure either of the light-giving energy or of the luminosity of a source of illumination. When used in the comparison of sources which differ in temperature, the indications of the photometer always yields us relatively too low a value for the intensity of the lamp of higher incandescence. In the case of candles *v.* gas, or either of these in comparison with the incandescent lamp at normal temperature, the error is not important, but between the candle and the "16-candle" lamp maintained at 50 candle-power, the discrepancy amounts to 10 per cent. For the electric arc the ratio of candle-power to total luminosity is very nearly 4 : 5, and in the case of daylight is about 4 : 6.

In arc light photometry candle-power is already a well-nigh meaningless term. Would it not be well to abandon it altogether in favour of some standard affording us an expression for the luminosity of radiation? So far as the incandescent lamp is concerned, light-giving power is a perfectly definite function of the temperature, and of the area of the radiating surface. We are, unfortunately, not in a position at the present day to measure the temperature of an incandescent filament, but the time will undoubtedly come when the relation between the temperature and the quality of the light emitted by glowing carbon will be definitely known. We may, indeed, look forward to the development of some optical method for the measurement of the temperature of incandescence which shall be as easily performed as our present method of determining candle-power, and which shall admit of a much higher degree of precision. The comparison of lamps, the temperatures of which are the same, will then reduce itself to a question of radiating surface. Total luminosity and total energy of luminous radiation, per unit of surface, together with net and gross efficiency, may then be expressed, in so far as incandescent carbon is our source of illumination, as functions of the temperature alone, and the performance of any lamp may be defined in terms which admit of no uncertainty.

ALTERNATE CURRENT WORKING.*

BY W. M. MORDEY.

(*Continued from page 439.*)

From Sir William Thomson's address, and from some further information he has kindly sent me, I have worked out and tabulated some figures, showing what restrictions are imposed by the virtual increase of resistance of solid conductors with alternating currents, as bearing on the question of periodicity.

Sir William Thomson gives some figures for a periodicity of 80, to which I have added some columns giving diameter in inches, sectional area, and the current which the practicable sizes will carry, taken on the basis of 450 amperes per square inch, because that density gives 1 per cent. loss per mile with 2,000 volts. It also gives about 1 per cent. loss per 100 yards with 100 volts, or, more exactly, 1·15 per cent. I have also given the number of watts at 2,000 volts, and at 100 volts, for each size, to show the limits for ordinary primary and secondary working with this density. These figures are given for 80, for 100, and for 133 periods, the diameters of conductors for the same percentage increase of virtual resistance over ohmic resistance being in the inverse ratio of the square roots of the periodicities.

Table I.—*Virtual Resistance, etc., of Conductors with Alternate Currents.*

Diameter		Area.		Increase over ordinary resistance.	Current at 450 amperes per sq. in.	Watts at 2,000 volts.	Watts at 100 volts.	Periods per second.
MM.	Inch.	Sq. mm.	Sq. in.					
10	·3937	78·54	·122	Less than $\frac{1}{100}$ %	55	110,000	5,500	80
15	·5905	176·7	·274	$2\frac{1}{2}$ %	133	266,000	13,300	
20	·7874	314·16	·487	8 %	220	440,000	22,000	
25	·9842	490·8	·760	$17\frac{1}{2}$ %	—	—	—	
40	1·575	1,256	1·95	68 %	—	—	—	
100	3·937	7,854	12·17	3·8 times	—	—	—	
1,000	39·37	785,400	1,217	35 times	—	—	—	
9	·3543	63·62	·098	Less than $\frac{1}{100}$ %	45	90,000	4,500	100
13·4	·5280	141·3	·218	$2\frac{1}{2}$ %	98·5	197,000	9,850	
18	·7086	254·4	·394	8 %	178	356,000	17,800	
22·4	·8826	394	·611	$17\frac{1}{2}$ %	—	—	—	
7·75	·3013	47·2	·071	Less than $\frac{1}{100}$ %	32	64,000	3,200	133
11·61	·4570	106	·164	$2\frac{1}{2}$ %	74	148,000	7,400	
15·5	·6102	189	·292	8 %	131·4	263,000	13,140	
19·36	·7622	294	·456	$17\frac{1}{2}$ %	—	—	—	

It will be seen that for 100 periods, with wires of 9 millimetres, or ·35in. diameter, the increase over the ordinary resistance is almost imperceptible; for a diameter of 13·4 millimetres, or ·53in., it is only $2\frac{1}{2}$ per cent.; while what may be considered a practical limit is

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

reached at 18 millimetres, or nearly ¾in. At greater diameters the increase is prohibitive, and multiple conductors, tubes, or strips must be used. Probably an increase of 8 or 10 per cent. will be considered quite permissible. It sounds a good deal; but it must be remembered that it is only 8 or 10 per cent. of the 1 or 2 per cent. loss for which primary conductors are usually calculated.

Looking at the limitations as regards output, it may be said that for primary distribution, even at no higher tension than 2,000 volts, the virtual resistance effect is, if not quite unimportant, at any rate not very serious. A current of about 200 amperes may be conveyed without the effect showing itself to any very objectionable extent. There may be differences of opinion on the subject, but most people will agree that 300,000 or 400,000 watts is quite as much as should be supplied through any single conductor. In most cases, even at ordinary tensions, subdivision of the primary will be necessary or advisable before such a power is reached. With still higher pressure, of course, enormous powers can be dealt with without exceeding the permissible size of solid conductors. It is to be observed that there is nothing in this virtual resistance effect to necessitate the reduction of current by the employment of very high pressures.

It is only with the low-tension secondary conductors that this effect becomes in any way serious. With 100 volts the maximum load at this density that can be put on a single solid or stranded conductor is about 13,000 watts for 133 periods, 18,000 for 100 periods, and 22,000 watts for 80 periods, unless much more than the 8 to 10 per cent. increase can be endured. This only means in large distribution work a subdivision of the primary and secondary feeding points in accordance with this limitation. The inconvenience has only to be recognised to be avoided. Fortunately it is not one that with ordinary care is likely to lead to any practical inconvenience. It exists with alternate currents, but it is a matter that the transformer system renders it very easy to avoid. Transformers lend themselves to subdivision of work, and with subdivision this difficulty does not exist.

It may be worth noting, in connection with this part of the subject, that the improvement in alternators, and the great ease with which they and their circuits can be worked and controlled, may lead to some revival of the practice of supplying direct from low-tension alternators. If this is done for any but very small installations, it is evident that special precautions must be observed to avoid the difficulties which have been referred to.

One other remark on this subject. Very large conductors are to be avoided in the transformers as well as outside of them. This is only mentioned on account of its bearing on transformers for any very low-tension work, such as electric jointing or welding, where one or two turns of secondary conductors is often sufficient.*

4. *Transformers.*—There appears to be a general belief that a high periodicity is best for transformers, and that this gives the greatest output, or—what amounts to the same thing—that with the same output in the two cases a higher efficiency is obtained when the periodicity is high than when it is low. This supposed fact has often been stated.

Prof. Forbes—who has, I believe, given much attention to the theory of this very difficult subject—contributed a paper last year,† consisting of a mathematical examination, which is summarised and concluded by a statement that the periodicity may be diminished without loss of efficiency if the iron be increased; the corollaries being, of course, that the periodicity may be increased without loss of efficiency if the iron be reduced, and that with any given transformer an increased periodicity results in increased efficiency for the same output, or in greater output with the same efficiency.

Prof. Forbes confirmed this view recently, in the discussion on a paper by Mr. Kapp before the Institution of Civil Engineers, by pointing out that one of the reasons why in America they used a high periodicity was that "they wanted to get the greatest output from their plant, and transformers had to be increased in size in order to give the same output if they lowered the number of alternations."* And in his recent paper on "Central Stations" before this institution,† Prof. Forbes reiterated this. He states that the contrary is "opposed alike to experience and theory. Westinghouse knows this. I am informed Mr. Ferranti knows it, and Mr. Zipernowski has told me that he finds it so."

Mr. Kapp, who works at 80 periods, does not go so far as Prof. Forbes, for he thinks that on account of viscous hysterisis there must be a limit beyond which an increase becomes disadvantageous. He wisely adds that it is not possible to determine this limit on theoretical grounds.

On the other hand, it has been said that it is not necessary to increase the size of transformers even for very low periodicities, because, when the number of cycles is small, it is possible to work at a higher magnetic density.

I venture to question the accuracy of both these extreme views.

So far as transformers are concerned, and speaking only from experience, I think that high and low periodicities are both wrong, and that a medium rate is right. For a given output and efficiency, not only must transformers be made large for low rates—they must also be made large for high rates; but between the two there will be found a periodicity giving the smallest size of transformer, or the greatest output, or the highest efficiency.

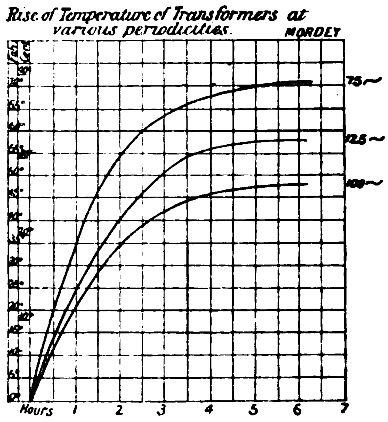

Fig. 2.

Fig. 2 illustrates this. It shows the rise of temperature of one of my transformers working respectively at 75, at 100, and at 125 periods per second. The primary and secondary virtual potential differences were measurably the same in all three cases, and in each case the same load was used, consisting of a certain number of glow lamps. The test was continued each time long enough for the transformer to attain its maximum temperature. This was taken by a sensitive thermometer, the bulb of which was placed directly on the iron, and covered by a packing of cotton waste to ensure that, as far as possible, at least the actual temperature of the iron should be indicated. Another similar thermometer was placed a few feet away to show the temperature of the room (which was fairly constant at about 60deg. F.).

The curves give the actual increments of temperature, which may be taken as some sort of measure of the relative efficiency attained. With any given output the same rise of temperature is, of course, always obtained with the same efficiency, quite apart from how the efficiency is made up. It will be observed that the lowest temperature or the highest efficiency is obtained at 100 periods; that the efficiency is lower at 125, and lowest at 75 periods.

On these lines I may suggest a method of arriving at the efficiency of transformers, which, though lacking in directness, is simple, and requires only ordinary appliances and facilities.

First run the transformer for some time in the usual way, on incandescent lamps, the output being measured. It is not necessary to make any measurements of the primary. By means of a thermometer find the rise of temperature of the transformer. Then, when the transformer has cooled down, send a continuous current through it, and measure the power in watts that raises the temperature of the whole transformer the same amount as when working with alternate currents. This takes some time to carry out; but it is accurate, and has the advantage that the lost power is measured in direct-current quantities, about which there is no question, while the power expended in the lamps, being in an inductionless circuit, is easily arrived at correctly. A wattmeter is the best instrument to use for the direct-current readings, as, on account of the rise of resistance of the conductor (which is necessarily required to carry much more than the usual current), some adjustment is necessary in order to keep the power constant, and this adjustment is effected much more conveniently with a wattmeter in circuit than if an ammeter and a voltmeter are used.

5. *Lamps, etc.*—Under this head, all apparatus for utilising or measuring alternate currents should be considered, so far as their action is affected by the periodicity. I must, however, confine myself to the lamps, which are the most important, and are the only apparatus as to which I can make any definite statements.

(To be continued.)

* The following particulars refer to conductors for primary circuits working at 2,000 volts, and show the sizes for various numbers of lamps giving a loss of 1 per cent. per mile run.

Data for copper conductors working with 2,000 volts pressure at the primary terminals of the transformers.

Transformers taken at 95 per cent. efficiency.

To allow 1 per cent. loss of pressure per mile of conductor, the primary current-density should be 450 amperes per square inch.

Conductor for any given number of 60-watt lamps.

Sectional area, in square inches = number of lamps × ·00007
Weight per mile, in lbs. = ,, ,, × 1·44
Resistance per mile, in ohms = 630 ÷ number of lamps.

The following conductors comply with the above rule, and none of them is effected by the virtual resistance effect:

Table II.

Number of lamps	B.W.G. No.	Diameter.	Sectional area.	Weight per mile.	Resistance per mile.
		Inch.	Sq. inch.	Lbs.	Ohms.
100	13	·098	·007088	144	6·3658
200	10	·134	·014102	286	3·1890
300	8	·165	·02138	433	2·1102
400	6¼	·191	·02865	578	1·5747
1,000	1	·300	·07065	1,433	0·6401

† "Formulæ for Converters," *Journal*, vol. xvii., p. 153. This paper was no doubt intended only as a mathematical investigation. It contains several assumptions that Prof. Forbes would probably not rely upon in practice.

THE LONDON COUNTY COUNCIL.

The usual meeting of the Council of the Administrative County of London was held on Tuesday afternoon in the Council-chamber at the Guildhall, the Earl of Rosebery, the chairman, presiding.

The Highways Committee reported that they had considered the various electric lighting schemes of the present session, and in connection therewith a letter from the Board of Trade and the objections of the vestries and district boards to the several schemes. They had also had before them reports from the solicitor and Mr. T. P. Gunyon, of the Engineers' Department, on the subject. and a further letter from the Board of Trade asking for the Council's observations on Major Marindin's report of the result of his enquiry into the several applications. The committee had very carefully considered the questions relating to the future of electric lighting in London, and had embodied the conclusions at which they had arrived in the following letter, which they recommended should be approved and sent to the Board of Trade :

"Sir,—The Council has had under consideration your letter of March 13 last, in which, referring to the electric lighting schemes of the present session, you express the wish of the Board of Trade to be furnished with any observations which the Council may have to offer upon the large and very important question of the future of electric lighting in London, and you refer especially to two questions of principle which have arisen in relation to the matter—viz.: (1) What should be the extent and nature of the area to be granted ; and (2) should or should not concurrent powers be granted to two or more companies within the same area ? The Council has also considered the further letter from the Board of Trade, dated May 18, forwarding copies of a report by Major Marindin, R.E., on the result of his enquiry into the applications for provisional orders and licenses under the Electric Lighting Acts, 1882 and 1888, as well as into the subject-matter of the Bill introduced into the House of Commons by the Metropolitan Electric Supply Company.

"The Council has directed me to submit the following suggestions and observations for the consideration of the Board of Trade when dealing with the electric lighting schemes affecting the county of London :

"The Council agrees that extensive areas may properly be granted to companies when their financial and technical means of carrying out the powers entrusted to them are of a satisfactory character, and accepts generally the recommendations of the report as regards the districts to be allotted to the several companies.

"The Council considers that, in the interest of the public, competition is desirable under proper restrictions.

"The Council is not prepared to offer any opinion or suggestion with reference to the scientific or technical portion of the report, but desires to express its full concurrence with the recommendation in Major Marindin's report that a company supplying a large area without a reserve of current should be required to provide duplicate sets of generating machinery in separate buildings, and duplicate sets of mains, in order to secure a proper and continuous supply in case of a breakdown of machinery or other default, and, further, that every possible means should be taken for guarding against danger to the public from currents of high tension.

"The Council concurs in Major Marindin's suggestion (2) that certain streets should be scheduled in each district for the compulsory laying of mains, and that the supply in the remainder of the area should be made compulsory, upon requisition of consumers, on fair and reasonable conditions, and suggests that in case of such supply not being afforded after a sufficient interval of time the order should be revoked as regards the whole of the parish or district in which such default occurs. It appears to the Council that without such a provision being made a company might be in a position to supply those parts of a parish or district where there was a good demand, and to leave unsupplied those parts of the area in which the demand was limited. The Council further suggests that the companies should be required in all streets where mains are laid to bring the supply at their own cost to the consumer's premises.

"The Council concurs in the suggestion (6) in Major Marindin's report that wherever a company now supplying a district by means of overhead wires is granted an order for such area the company should be placed under statutory obligation to remove these overhead wires within two years from the granting of the order, and that, if possible, such company should be prevented from invading a district in which it has no statutory powers by means of overhead wires ; and the Council suggests that it should be an indispensable condition of the granting of any application for an order or license that in the area referred to therein all wires and mains should be laid underground.

"With reference to clause 55 of the London Company's order, which would enable the company to supply electricity to a vestry or district board for the latter to retail to consumers, the Council considers the expediency of granting such a power to be doubtful, and would suggest that, if allowed, a provision should be inserted that the power given by the clause shall in no case be acted upon without the consent of the Council having been first obtained.

"The Council also submits the following general suggestions applicable to all the orders and licenses, namely :

"(*a*) That the terms and conditions of all orders or licenses granted should be as nearly as possible identical.

"(*b*) That companies should be required not only to make use, with the consent of the Council, of subways now made, or which may hereafter be constructed, in streets where mains are to be laid, but to pay a fair rent for such use ; and, further, that in case of subways being in future made in streets where wires are already laid, the companies should be under an obligation to remove the wires into such subways, and to pay a rent for the use of them, a reasonable time (say three years), free of rent being allowed as a set-off to the cost of such removal ; that the power to make subways in the London streets should be vested in the Council, and not in the local authorities of the several districts.

"(*c*) That provision should be made to prevent the opening of any thoroughfare in the county of London for the purpose of laying mains, etc., until the consent in writing of the Council shall have been given to such opening.

"(*d*) That provision should be made for exempting the Council, and the vestries and district boards from liability in respect of any damage which may be done to mains, etc., in carrying out works of repair or improvement in streets or roads, or from the use of steam-rollers in the execution of such works.

"(*e*) That provision should be made for preventing interference with main or local sewers, or with the proper access to them, without the consent of the authorities in which such sewers are vested ; and that plans of works which would interfere with sewers in any way should be submitted for the approval of such authorities before the works are begun.

"(*f*) That, in view of the future possible reduction in the cost of production which may be made as the result of experience and invention, there should be a provision that the maximum price of 8d. per Board of Trade unit proposed to be adopted shall be subject to revision at the end of seven years ; and that, in order to ensure healthy competition between the companies during that period, (1) no amalgamation or working agreement between companies should be permitted without the consent of the Council, and (2) power should be given to the Council, at the request of a vestry or district board or on the requisition of inhabitants in any street or district, and with the consent of the company interested, to extend the area of such company to such street or district without the necessity of obtaining another order.

"That clauses should be inserted providing for the application at the end of the seven years of a sliding scale of price and dividend, on the basis of a dividend of 8 per cent., leaving the initial price and arrangement of the scale to be determined at the expiration of the term of seven years.

"That provision should be made that electricity supplied to local authorities for the purpose of public lighting shall be charged for at a less price than that charged to private consumers.

"That the minimum charge for supply should be fixed as low as possible ; and that should such minimum be fixed at £1 per quarter or over it should be reckoned by the year and not by the quarter because of the irregular requirements of the consumer at different seasons of the year.

"(*g*) That for the purposes of purchase by a public authority, any additions made to the area of supply of any company shall be taken to be part of the original area granted to such company, and that the powers over the additional area shall terminate at the same time as those over the original area, unless at the time the additional powers are granted to the company it shall be expressly stated to the contrary.

"The Council considers it would be to the advantage alike of the public and the companies that there should be one uniform system of regulation and control throughout the entire area of London. The necessity of this was forcibly illustrated by the very varied, and in many respects inconsistent, objections and requirements of the different vestries and district boards in regards to the proposed orders and by the complication and difficulty occasioned thereby.

"The Council is of opinion that, as the representative governing body of the county of London, it should be appointed the controlling authority. It would always give the fullest consideration to the representations of any local body on questions affecting its particular interests. The Board of Trade may be reminded that the main roads throughout the metropolis will shortly come under the jurisdiction of the Council, and should any general system of subways be hereafter resolved upon such system will also be under its control. The Council considers also that it should be the authority to whom should be given the power of purchase in all cases at the expiration of the specified period ; it would be manifestly impossible for any single vestry or district board to purchase a large undertaking supplying many parishes, such as that of the London or the Metropolitan Company. The Council would further suggest that if it is made the controlling authority it should be empowered to discharge the following duties—viz.: Inspection of lines and works ; testing current ; testing and certifying meters ; taking proceedings for imposition of penalties or forfeiture in cases of default as provided in the orders.

"And in order to carry out the work of testing it should be made obligatory on the companies to provide and maintain a sufficient number of testing stations, and proper and efficient testing apparatus.

"The Council, in view of the fact that some companies have been and are now supplying electricity by overhead wires without statutory powers, and being convinced of the undesirability of allowing this to be continued, would venture to suggest that in any future legislation on electric lighting the supply of electricity in any district before statutory powers have been obtained for such district should be prohibited under penalty.

"The Council, in submitting the above suggestions, is animated by a desire to facilitate the working of the companies' undertakings in the various areas to be allotted to them, and at the same time to ensure that the interests of the public are properly guarded.

"Some of the orders will affect the bridges, embankments, and other works under the jurisdiction of the Council, and the Council reserves any expression of opinion upon the manner in which its interests should be protected, as also upon other general matters of detail, until it shall have received the copy of the model order referred to in the letter from the Board of Trade of the 18th of May.—I am, Sir, your obedient servant, H. De La Hooke, clerk of the Council.

"The Assistant Secretary, Railway Department, Board of Trade."

Digitized by Google

Mr. Haggis, in presenting the report, said the committee had taken a comprehensive view of the whole question.

Mr. Antrobus suggested, in the interests of the companies, that there should be an appeal to the Board of Trade.

Sir T. Farrer said the letter had been drafted with the very greatest care, and it met almost all the points that the Board of Trade would wish to have before it. The terms of purchase by the municipality were provided for by the Act, and with those terms the Council had nothing to do. They did not depend on the dividend paid nor the price on the Stock Exchange. He would strongly urge the Council, as far as his knowledge of the subject was concerned, to adopt the letter.

Mr. Torr opposed any appeal to the Board of Trade.

After some further discussion the letter, with a few verbal amendments, was approved, and ordered to be forwarded to the Board of Trade.

Mr. Fardell, in submitting the report of the Theatres and Music Halls Committee, said he did not approve one of the recommendations. The committee were of opinion that it was necessary, in the interest of the public safety, that there should be a periodical systematic inspection of all theatres and music-halls under the Council, and they had had before them a form of authority, prepared by the solicitor, enabling persons to enter these buildings for the purpose of inspecting them, in accordance with the provisions of the Acts of Parliament on the subject. The committee had also considered the question of the persons to whom it was desirable that this authority should be entrusted, and having regard to the duties assigned to the committee by the Council and to the large number of licensed places to be dealt with, they were of opinion that every member of the committee should be in a position to inspect at any time any of these places. They therefore recommended that the form of authority for the entry of theatres and music-halls be approved, and that a sealed copy be given to each member of the committee and also to the superintending architect and to two assistants. He objected to the form of authority being given to each member of the committee.

Mr. Marks moved the omission of those words.

After some remarks from **Captain Verney** and **Mr. Macfarlane**,

Mr. H. L. W. Lawson believed it would be absolutely futile that casual expeditions should be made by one or more members of the committee to theatres and music-halls in London, even with the best intentions in order to secure public safety and convenience.

Mr. Beachcroft agreed that there was necessity for a periodical inspection of theatres, but did not think it should be done in the way suggested.

Mr. Charrington said it could not be too widely known that they had the right and power with regard to the old theatres of having reasonable alterations made.

Mr. Clarke said the powers which the committee now sought to obtain were exercised by the police on the Continent.

Mr. Brudenell Carter held that there was no necessity for giving this power to members of the committee and making them practically inspectors of theatres.

Mr. Torr supported the recommendation of the committee.

Mr. G. W. R. Russell said it would have a wholesome influence if it were known to the managers of those premises that there was a certain number of gentlemen armed with a roving commission to visit and report on them.

Mr. N. Robinson advised the committee not to let their zeal carry them too far.

The **Rev. Fleming Williams** said there had been several attempts to reduce a serious question to the level of the ridiculous and to laugh it out as being unworthy of attention, but the people of London expected them not only to appoint a committee that should have charge of the structural adequacy of the arrangements in these theatres, but a committee that should be sensitively alive to those moral conditions that ruled them in granting licenses.

The **Chairman** said he was sorry to have to differ altogether from the last speaker and the many serious and earnest men who had taken part in the debate, but his first duty was to the Council, and he wished to point out to them that as this discussion went on it broadened out very considerably. Till the last speaker spoke they had no intimation that anything was understood except the inspection of the safety of exits. They had now suddenly had the idea that it was proposed to let loose on the theatres and music-halls of London a vigilance committee of thirty men, each of them with a passport in his pocket allowing him to go into every theatre to examine, not merely the safety of that theatre for the purposes of the public convenience, but also as to the morality of the piece. Such an idea, when once promulgated as the deliberate conclusion of the County Council, would produce a feeling of stupor throughout the whole metropolis. He pointed out that the Theatres Committee might, under the Act, surely obtain their object in another and less objectionable way, and begged the Council not to let a report go forth to London the next day that 30 of their members were proceeding about the metropolis with the right to enter any theatrical performance free at any hour and at any time. Those were the sentiments which, in deference to the wish which had always impelled him since he had occupied the chair—namely, to make the Council efficient and successful—he felt bound to express.

The amendment was adopted, and the rest of the report approved.

Mr. Foster had given notice of a motion to the effect that the chairman of the Council be requested to express to the Prince of Wales the deep regret of the Council at the personal inconvenience caused to him and the Princess of Wales at the Fire Brigade inspection on Saturday, May 25, and that a special committee be appointed to enquire into the arrangements made by the Fire Brigade Committee for the inspection of the Fire Brigade on Saturday, May 25. He said he thought the Council had learnt a lesson in making better arrangements for the future for any public function, and he therefore asked leave to withdraw his motion.

After some discussion the motion was by leave withdrawn.

Mr. Wren moved: "That it be an instruction to the Sanitary and Special Purposes Committee to take into consideration the causes of the fogs which trouble London during the winter months and the increased death-rate during their prevalence in order to put in force existing powers for dealing with them and obtaining increased powers, if necessary."

Mr. Brudenell Carter objected to the Sanitary Committee being saddled with a reference which, he apprehended, it had no power to conduct to a successful issue, and said the question could be much better considered by a special committee.

The motion was adopted, and the Council adjourned.

COMPANIES' MEETINGS.

UNITED TELEPHONE COMPANY.

The ninth annual ordinary general meeting of the United Telephone Company was held on Tuesday at the City Terminus Hotel, under the presidency of Mr. James Brand.

The **Chairman** stated that during the last few months the accounts had been subjected to very severe inspection by their two subsidiary companies, with whom, he hoped, they were now going to amalgamate, as well as by the Company's auditors. They all agreed that the Company could pay a dividend of 17½ per cent., at the same time increasing their reserve fund by about £10,000, arising from premiums on new shares issued. Their share capital was now £500,000 against £483,000 last year. As to revenue, they would carry forward £4,000 more of unearned subscriptions for the benefit of next year. To meet the wishes of many subscribers they had established an all-night service throughout the West-End of London, Chancery-lane, King's Cross, etc. So far the calls had been few, but they were gradually increasing. They had now 28 call-rooms in and about London open, and nine more would be opened very shortly. They had also concluded an arrangement with the Aerated Bread Company, which would very soon cause the opening of something like 80 fresh call-rooms in the most frequented places in London. A local exchange had been opened at Bromley, in Kent, which was now being joined to their London system by trunk. They had already an independent trunk line between London and Croydon, and a local exchange with 42 subscribers. The Brighton business in itself was, he believed, doing very well for the South of England Company, but the United Company had not had the success they had hoped for, as far as the intercommunication with London was concerned. The South of England Company had now entered into a special arrangement with them for the purposes of a call-room between London and Brighton, and they hoped to induce a large telephonic business between the two places and the intermediate towns. They had acquired space within the London Stock Exchange, and were erecting a special trunk line between the Stock Exchanges of London, Liverpool, and Manchester entirely for the use of members of these exchanges. He then referred to the action which the Company had taken against the Equitable Telephone Association and the New Telephone Company, and said he believed that in the face of the complete collapse of those companies, with a total loss of their capital, similar companies were not likely to be started during the remainder of the terms of the patents belonging to the United Company. Alluding to the question of amalgamation, he stated that the matter was first considered two years ago. By the union, difficulties and differences which now existed would be overcome, and the work would be carried out under one management. The Postmaster-General, who, in the pursuit of the duties of his office, was a very keen trader, would certainly be more able to bring his devices to pass if he had to deal with the various companies singly, and one after another, than if he had to deal with one great company, strong in unity, in financial position, and with one strong executive body. As to the reason for uniting the three companies, and under the name of the National Company, instead of the two other companies coming together under the wing of the United Telephone Company, the Postmaster-General had inclined to grant the latter permission to assign its license, on the ground, he (the speaker) understood, that the monopoly created by such a license, and by such acquiescence in their desires, would be contrary to public policy and injurious to the interests of the public by the clearing away of competition. The Postmaster-General, however, knew full well that ever since the granting of the separate license to each company there had been no competition, as each company had worked its own territory without interfering with its neighbour. As soon as they had proved that the telephone was no plaything, but was going to be a commercial success, the Postmaster-General said that, after all, the invention was only a telegraph, and that if the Post Office allowed them to use it, they must pay £10 out of every £100 gross received by them. That tax now amounted to nearly £35,000 a year; but finding that, in spite of this burden, they were getting stronger and more useful every day, the Postmaster-General pursued the old tactics placing every obstacle in the way of their progress. He concluded by moving the adoption of the report and the payment of the dividend recommended.

Mr. J. S. Forbes seconded the motion, which was unanimously carried.

Resolutions were afterwards submitted *seriatim* approving the amalgamation agreement, winding up the Company voluntarily, appointing Mr. T. A. Welton liquidator, and authorising the liquidator to carry the agreement into effect.

In answer to questions, the Chairman stated that they knew they were within the law in what they proposed, and so did the authorities

Digitized by Google

of the Post Office. What they had done they had done most openly. The new board would consist of the present Directors of the United Company and four directors of each of the other two companies.

The resolutions were agreed to.

The following letter has been addressed by the Postmaster-General to the Secretary of the United Telephone Company:

"General Post Office, June 4, 1889.

"Sir,—The Postmaster-General has had his attention called to the notice issued by the United Telephone Company to its shareholders on the 24th ult., and to the course which the telephone companies propose to pursue with the view to an amalgamation.

"Whether such course can be legally adopted under the terms of the licenses granted by the Post Office is a question on which the Postmaster-General does not at present offer an opinion; but he desires me to acquaint you, for the information of the Directors and shareholders of the United Telephone Company, that the amalgamation of the companies was not contemplated when the licenses were issued, and that any assurances, outside the licenses, which the companies may conceive themselves to have received from the then Postmaster-General cannot be regarded as applicable to the state of things likely to result from the proposed amalgamation.—I am, etc.,

S. Arthur Blackwood.

"The Secretary United Telephone Company."

NATIONAL TELEPHONE COMPANY.

The ninth annual ordinary general meeting of the National Telephone Company was held at the City Terminus Hotel, Colonel R. Raynsford Jackson presiding.

The **Chairman**, in moving the adoption of the report, observed that they had to consider not only the ordinary business, but what was practically an amalgamation of the Company with the United and the Lancashire and Cheshire Telephone Companies. With reference to their business, in the last ten months they had had a period of prosperity. The number of subscribers had increased by 1,489, the total number now being 10,813. The mileage of the trunk wires had increased by 1,238 to 3,747, and the total mileage of their wires was now 13,583. Their gross revenue for the ten months ended April 30 had been £125,978, the increase for the ten months being £16,405. The number of exchanges had been increased by 18, making the total 135, and the call-offices by 61, making a total of 277. The net revenue for the ten months had been £42,338, and after paying the debenture interest and the preference dividends they proposed to pay a dividend for the ten months at the rate of 5¼ per cent. on the ordinary shares. It might be asked, if the Company had been so prosperous, what reason was there for amalgamating with the two other companies? After long negotiation, however, the Directors were quite satisfied that the terms which had been arranged with the other companies were fair and equitable. An amalgamation would effect a great reduction in the aggregate expenditure of the companies. They would be able to give the public a much better service all round than at present, and they would be able to meet the wants of a variety of interests which were, to a certain extent, neglected at present. It was to be remembered, also, that the National Company had been, and was, in a peculiar position in reference to the United Company, which possessed one-half of the voting powers in most of the sub-companies, the National Company among them. The sub-companies could not issue additional capital without the sanction of the United Company, and they were limited in the form of issue. By the amalgamation all these difficulties would be got rid of, and their hope was that the result of the amalgamation would be to make London the heart and centre of a huge telephonic system, embracing its own suburbs and such of the industrial towns of the United Kingdom as might desire to have a constant and easy telephonic connection with it. He thought that by giving greater facilities to the public the combined companies would do very much to popularise the telephone, and on the part of the public induce a feeling of more cordiality towards telephonic enterprise than at present existed. Colonel Williams, who had resigned his position at the Board, had issued a circular in which he had contended that the interests of the National Company had been sacrificed to those of the United Company, and arguing that the amalgamation would be received by the Postmaster-General with feelings of resentment. Quite apart, however, from the votes of the United Company the Directors' proposals were supported by a majority of more than three-fourths of the capital of the National Company. He dissented altogether from the notion that the amalgamation would be regarded as an act of hostility to the Post Office. The result of the arrangement which had been arrived at after the fullest consideration was that the United Company were to receive in the new National Company £1,250,000 of the capital, the National Company £720,000, and the Lancashire and Cheshire Company £525,000. These figures, so far as the United Company was concerned, included the value of that company's holdings in the National and the Lancashire and Cheshire Companies, amounting together to £290,625, which would have to be deducted from the total capital, reducing the capital of the three companies, as amalgamated, to, in the first instance, £2,204,375.

Mr. John Bruce seconded the motion, which was adopted, the dividends recommended being afterwards declared.

The **Chairman** then proposed the resolution, in effect approving an agreement for the amalgamation of the three companies named.

Mr. Peter Garnett seconded the motion.

Colonel Williams, who said he represented many *bonâ fide* shareholders in the Company, in the course of a long speech reiterated the statements made by him in his circular.

Mr. W. A. Smith, of Glasgow, said he represented between one-fourth and one-fifth of the independent body of shareholders, and he and those whom he represented were just as strongly in favour of amalgamation as Colonel Williams was opposed to it.

The **Chairman, Mr. Leyland** (a Director), and **Mr. J. S. Forbes** (the deputy-chairman of the United Telephone Company) also replied to Colonel Williams, Mr. Forbes observing that each of the companies was of opinion that a bad bargain had been made on its behalf. The proposed union would place them in such a position that when the time came for open competition—by the expiration of the patents—they would be able to defy not only the Postmaster-General and his department, but any outsiders.

The motion was then adopted, with one dissentient—Col. Williams—and resolutions were afterwards passed authorising the Directors to increase the capital by £3,250,000 by issuing 650,000 shares of £5 each; adopting new regulations for the Company, and, in compliance with the agreement, removing the existing Directors as from the date of the confirmatory meeting.

The **Chairman** stated that the new Board would consist of Messrs. C. S. Agnew, J. W. Batten, J. Brand, John Bruce, J. S. Forbes, Peter Garnett, E. Heyworth, F. R. Leyland, J. B. Morgan, D. Parrish, W. C. Quilter, M.P., G. H. Robertson, S. H. Sands, Colonel Jackson, and Alderman J. Thompson.

CITY NOTES.

Great Northern Telegraph Company.—The receipts for the month of May amounted to £22,800.

Direct Spanish Telegraph Company.—The receipts of this Company for May were £2,040, against £1,800.

West Coast of America Telegraph Company.—The receipts of this Company for the month of May amounted to £6,975.

Eastern Telegraph Company.—The receipts for May were £52,704, as against £49,003 for the same period of 1888, or an increase of £3,701.

Cuba Submarine Company.—The traffic receipts of this Company for May were £3,500, against £3,337. The receipts for February, estimated at £3,200, realised £3,204.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended May 31 show an increase of £100, as compared with the corresponding period.

Lancashire and Cheshire Telephonic Exchange Company.—This Company have declared a dividend of 8¼ per cent. for the 10 months ended April 30, less the interim dividend paid in March last, £1,761 being carried to reserve.

Western and Brazilian Telegraph Company, Limited.—The receipts for the week ended May 31, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,835.

Brazilian Submarine Telegraph Company, Limited.—The Board of this Company have declared an interim dividend of 5s. per share for the quarter ended March 24, payable on the 24th inst. The receipts of the Company for the week ended May 31 amounted to £3,960.

National Telephone Company, Limited.—This Company, in their report of the ten months ending April 30 state that the accounts are made out for a period of ten months to the above date, instead of as usual for an entire year, this change being consequent upon the proposed purchase by the Company of the United Telephone Company, Limited, and the Lancashire and Cheshire Telephonic Exchange, Limited, in accordance with agreements which will be submitted to the meeting for approval. The capital expenditure for the above period was £52,747 and the gross revenue £97,426, the amount carried forward being £63,053. The annual rentals on the 30th of April reached £121,978. There is also a revenue derived from fee messages, at the rate of £4,000 a year, making the total gross revenue reached on the 30th of April £125,978, against £109,572 for the year ending June 30, 1888. After providing for the accrued interest on the debentures, for a dividend for ten months at the rate of 6 per cent. per annum on the amount paid up on the first and second preference shares, and after having paid an interim dividend for the first half of the year at the rate of 4 per cent. per annum on the ordinary shares, there remains a balance of £15,952, out of which the Directors propose a dividend making up the distribution on the ordinary shares to the rate of 5¼ per cent. per annum for the ten months. Of the balance then remaining they propose to place £2,500 to the reserve fund and to carry forward £2,765.

NEW COMPANIES REGISTERED.

Electric Construction Corporation, Limited.—Registered by Linklater and Co., 2, Bond-court, Walbrook, E.C., with a capital of £500,000 in £10 shares. Object: to adopt an agreement with reference to the sale and purchase by the Company of certain business patents; to carry on the said businesses, and to construct, contract for, establish, carry on, or to finance upon expedient terms for other companies, firms, corporate or municipal bodies, to enable them to establish machinery for lighting streets, public and private buildings and premises of every kind by electricity, either alone or in conjunc-

Digitized by Google

tion with other means, and for any purpose of light, heat, electric, magnetic or other force. The first subscribers are :

	Shares.
Sir C. Fox, Coombe Spring, Kingston-on-Thames	1
Sir D. Cooper, Bart., 6, De Vere-gardens, W.	1
J. Pender, Thornley Hall, Rugby	1
Sir H. C. Manse, Manora, Bedford	1
J. Verity, King-street, Covent-garden	1
J. I. Courtenay, 1, Essex-court, Temple, E.C.	1
J. Smith, Oakeswell Hall, Wednesbury	1

There shall not be less than three nor more than 15 Directors. The first to be appointed by the subscribers to the memorandum of association. Qualification, £1,000 stock. Remuneration, £3,000 per annum, and, in addition, £250 for each Director over 11, and an additional £1,000 for every 1 per cent. profit after 10 per cent. dividend. Such remuneration to be exclusive and in addition to the remuneration payable to J. Smith and T. Parker, as managing and works Directors.

Halifax and Bermudas Cable Company, Limited.—Registered by Saxelley and Faulkner, 7 and 8, Ironmonger-lane, E.C., with a capital of £50,000 in £5 shares. Object : to establish, maintain, and work lines of telegraphic communication between Halifax, Nova Scotia, and the Bermudas. The first subscribers are :

	Shares.
E. A. Field, 8, Oxford-terrace, W.	1
S. Johnson, 9, Inverness-terrace, Hurlingham	1
J. Whitaker, 11, Benedict-road, Brixton	1
J. Yorn, 59, Blackheath-road, S.E.	1
N. Cassell, 41, South-hill-road, Hampstead	1
W. Daniells, 20, Granville-square, W.C.	1
W. Pitt, 39, Sandbrook-road, N.	1

There shall not be less than three nor more than seven Directors ; the first to be appointed by the subscribers to the memorandum of association. Qualification, £500 stock. Remuneration : Chairman, £300 ; other Directors £200 per annum.

Woking Electric Supply Company, Limited.—Registered by Bircham and Co., 46, Parliament-street, S.W., with a capital of £20,000 in £5 shares. Object : the construction of works, machinery and apparatus for lighting streets, etc., by electricity. The first subscribers are :

	Shares.
E. Stevenson, 38, Parliament street, S.W.	1
J. Mackenzie, 15, Great George-street, S.W.	1
H. S. King, Founders' Hall, E.C.	1
E. Maunce, 46, Parliament-street, S.W.	1
S. Chadwick, 17, Spencer-street, S W.	1
S. Bircham, 46, Parliament-street, S.W.	1
E. Price, 15, Holderness-road, Tooting	1

There shall not be less than three nor more than five Directors. The first are H. C. Masterman, E. Stevenson, S. C. Phillips, A. G. Gale, and H. S. King. Qualification, £100 stock.

Portsmouth and South Hants Electricity Supply Company, Limited.—Registered by C. Doubble, 14, Serjeant's-inn, E.C., with a capital of £50,000 in £5 shares. Object : to form centres in Hants, at which electric power may be generated or accumulated, and from which the same may be distributed for the purpose of lighting private houses, or street lighting, etc. The first subscribers are :

	Shares.
Colonel C. L. Owen, J.P., Portsmouth	5
R. Ford, Portsmouth	5
W. Edmonds, Annesley House, Southsea	5
H. Holbrook, Holmwood, Southsea	5
A. White, North End, Portsmouth	5
R. Hammond, 117, Bishopsgate-street, E.C.	5
Colonel Mumby, Spring-gardens, Gosport	5

The number of directors shall not be less than four nor more than nine ; the first to be appointed by the subscribers to the memorandum of association. Qualification, 50 shares. Remuneration, £400 per annum, with additional $\frac{1}{15}$ on all profits after 5 per cent. dividend, divisible as they determine.

PROVISIONAL PATENTS, 1889.

MAY 27.

8697. **Improvements in electric musical mechanism.** Stanley Herbert Gibson, 34, Southampton-buildings, London.

8709. **Amalgamating gold by electricity and mechanical motion.** Emile Hippolyte Marie Andreoli, 62, Loughborough-park, Brixton.

8769. **Improvements in electrical measuring instruments.** Arthur Cecil Cockburn and John Nealor Cooper, 32, Gaisford-street, Kentish Town-road, London.

8776. **A combined postal, electric signal alarm and telephone pillar.** Edward Hasselbach, Maurice Henry Hyman and Jacob Alexander Alexander, 55 and 56, Chancery-lane, London.

8780. **Improvements in electrical switches.** Edouard Emmanuel de Facien, 33, Chancery-lane, London.

8793. **Improvements relating to screw-cutting lathes and to electrical indicating apparatus for use in connection therewith.** William Howard Winnall, 4, South-street, Finsbury, London.

8800. **Improvements in regulators chiefly designed for use in electric arc lamps.** Henry Harris Lake, 45, Southampton-buildings, London. (Otto Heinrich Louis Lindemann, Germany.)

MAY 28.

8815. **Improvements in devices for automatically interrupting an electric circuit under predetermined conditions.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Westinghouse Electric Company, United States.)

8855. **Improvements in secondary batteries or accumulators.** Thomas Harris and Henry Francis de Bathe Cameron, Detroit, Michigan, United States. (Complete specification.)

8861. **Improvements in electric switches.** Oliver Imray, 28, Southampton-buildings, Chancery-lane, London. (Walter Thompson, United States.) (Complete specification.)

MAY 29.

8905. **Receiving and transmitting an electric current for telephonic, telegraphic, or other electrical purposes, viz., "The anti-alternate current relay."** Alfred George Burrell, 5, King-street, Sheffield.

8925. **Improvements in electric batteries.** Charles Wells, 22, Southampton-buildings, Chancery-lane, Middlesex.

8944. **Improvements in electrical switches or commutators.** Douglas Clavell Bate, 6, Derwent-grove, East Dulwich.

8958. **An electric meter.** Alphonse Frager, 28, Southampton-buildings, Chancery-lane, London.

MAY 30.

8979. **Improvements in electric switches.** Frederik Vilhelm Andersen, 3, Elm-court, Temple. (Complete specification.)

8986. **Improvements in secondary batteries.** David Urquhart, William Bates, and Frank Wynne, 11, Victoria-street, S.W.

8999. **Improvements in electrical tramways or railways and apparatus therefor.** John Hopkinson, 47, Lincoln's-inn-fields, London.

9013. **Improvements in arc lamps.** Thomas Stanley, Alfred Henry Davies and John Joseph O'Connor, 8, Quality-court, London.

MAY 31.

9034. **Improvements in self-contained dome electric bells.** Wm. Pressland and William Thomas Pressland, 4, Little Moorfields, London.

9066. **Improvement in railway fog signals—viz., "The electric fog signal."** Edgar Alexander Harvey and Martin Edward Brooke, Brookdale, Lindley-road, Leyton, Essex.

9074. **Improvements in the electric ignition of gas.** Richard Warwick, 20, High Holborn, London.

JUNE 1.

9093. **Improvements in storage batteries.** August Jung, 6, Lord-street, Liverpool.

9096. **Improvements in telephonic switch boards.** Hubert Fielden Jackson and Daniel Sinclair, 62, St Vincent-street, Glasgow.

9119. **Improvements in electric bells.** Edward Thomas Fiford, 21, Cockspur-street, London.

9133. **Improvements in the manufacture of carbons or electrodes for electric lamps.** Henry Harris Lake, 45, Southampton-buildings, London. (Messrs. Lacombe and Co., France.)

SPECIFICATIONS PUBLISHED

1887.

14542. **Electric motors.** Sandwell. (Reprints with alteration.) 11d.

NOTES.

A New Cable.—Advices from Brussels state that it is proposed to lay a telegraphic cable from Ostend to America.

Brazil.—The Brazilian Government are prepared to receive tenders up to October 30 for the laying of one or more submarine cables between Brazil and the United States of America.

Electric Lighting in France.—The town of Louhans (Saône-et-Loire) will be lighted by the firm of X. Garnot, of Paris, from the first of next October. The concession is for 20 years.

The Phonograph.—It is stated that Edison has made a discovery in relation to the coating of the phonographic cylinder which will materially improve the quality of enunciation.

A Train Struck by Lightning.—On the 23rd of last month a train on the line from Utiel to Valenza was struck by lightning. One of the cars was wrecked. No deaths are reported.

Electric Sugar.—The "electric sugar" case is now being heard, the Rev. W. E. Howard, father-in-law of Prof. Friend, now being on trial in Part 1 of the New York Court of General Sessions.

Electric Light and Insurance.—There are 1,300 buildings in Philadelphia furnished with electricity for light or power purposes, and on not one of these has there been any loss by fire for two years past.

Going Ahead.—It seems only yesterday that we heard of the rush to Oklahoma, and now we hear of the Mayor being instructed by the Council to appoint a committee of three to consider the question of electric lighting.

French Omniboats.—The omniboats plying on the Seine in connection with the Exhibition have each received an installation consisting of a small 5-h.p. engine and a Breguet continuous-current dynamo. These serve 17 incandescent lamps, conveniently arranged in the cabins, the engine-room, etc.

Busy.—The New York *Electrical World* is informed that Mr. Harold P. Brown has been quite busy making arrangements to supply the State authorities with the apparatus needed for electrical execution. Fortunate Mr. Brown. We hear that the date of the much talked of execution has been postponed.

Printing by Electricity.—The printing presses of the *Chronicle*, published at Spokane Falls, Washington Territory, has been run by a 2 h.p. Sprague motor for over a year. The proprietors say that during this time the motor has not cost them one cent for repairs, and is in as good a condition as when installed.

Elwell-Parker's.—We are informed that Elwell-Parker, Limited, had just acquired for their new electric engineering works a site of not less than 24 acres, at Bushbury, a village two miles from Wolverhampton, on the way to Penkridge. Under the new arrangement it is to be presumed that the site will be taken over by the Electric Construction Corporation, Limited.

Proposed Lighting at Mannheim.—The municipal authorities at Mannheim have been considering the question of electric lighting, and Mr. Uppenborn and Prof. Kittler were instructed to furnish independent reports as to the advisability of establishing a central station. Both reports are in favour of the project, but it is recommended that the works be at first carried out experimentally.

Capital Punishment in France.—It is now proposed to abolish the guillotine, and subtitute death by electricity for the capital punishment in France. It is pleasing to think that there may be a fund of truth in the oft-repeated assertion that "electricity is life," but we must confess to a feeling of horror that the heavenly fluid should be made to fill the base offices of executioner.

Zigang's Telephone.—The principal point in connection with Capt. Zigang's electromagnetic telephone seems to be his discovery "that when a telephonic membrane is acted upon by an undulating current through the intermediary of an electromagnet the currents obtained are, up to a certain limit, more intense and more distinct, as the size of the membrane is limited and its elasticity increased." The apparatus is constructed in conformity with this theory, and is said to possess an advantage over magnetic telephones in that it is less affected by induction currents from neighbouring wires.

Interesting Papers.—Some interesting papers have recently been read in America. Among them may be mentioned the following: "Electric Motor Regulation," by Francis B. Crocker; "The Efficiency of the Arc Lamp," by Hatsune Nakano, being a note on Mr. Ernest Merritt's paper on "Some Determinations of the Energy of the Light from Incandescent Lamps"; "Magnetism in its Relation to Induced E.M.F. and Current," by Prof. Elihu Thomson; "The Spiral Coil Voltameter," by Harris J. Ryan; and "On Modern Views with Respect to the Nature of Electric Currents," by Prof. H. A. Rowland.

Ship Lighting.—The installation on board the new twin-screw steamer "Augusta Victoria," running between Hamburg and New York, is said to be exceptionally well arranged. The plant consists of four Schuckert dynamos, driven by four Vulcan engines, supplying 800 16-c.p. Siemens and Halske lamps distributed throughout the vessel. In the dining-saloon are a great number of small electroliers, each holding three lamps of opalescent glass Each cabin is provided with a single lamp encased in a cream-coloured globe, giving it much the appearance of a miniature arc lamp. The dynamos give 300 amperes and 60 volts at a speed of 450 revolutions per minute.

The Lighting of Weybridge.—The lighting inspectors, in view of the number of promises of support which have been received, have invited tenders from some of the principal electricians in the country. We understand that amongst them Mr. Kenneth Mackenzie, A.M.I.C.E., M.I.E.E., the engineer of the Woking Electric Supply Company, has been asked to tender, it being stated that the estimated demand would be for about 100 street lamps and 800 inside lights. We believe that, as an alternative scheme, Mr. Mackenzie will suggest that mains should be laid from Woking to Weybridge (a distance of six miles), and the light supplied from the works, which are to be forthwith commenced at Woking.

Another New Cable.—We are informed that the Telegraph Construction and Maintenance Company has signed a contract for laying a direct cable from Europe to Buenos Ayres. The Government of the Republic guarantees five per cent. to the shareholders. The number of messages now sent through the Brazilian Submarine and

Digitized by Google

the Western Brazilian to the territory of the Republic is said to be sufficient to pay at least four per cent. on two millions sterling. A new company will be started to take up the contract. The Telegraph Construction and Maintenance Company will be the vendors, and Sir John Pender the chairman. Why! Certainly! When this company comes out we shall have something to say about it.

Progress in Australia.—Advices from Sydney, New South Wales, state that at a meeting of the Balmain Council, held in April last, it was agreed to accept Mr. Montague Rhys Jones's offer to construct an electrical tramway at Balmain. The concession will be in force for a period of 21 years, at the expiration of which time the Council has the power of purchase. Mr. Jones, who is one of the firm of Messrs. M. R. Jones and Co., engineers and contractors, of Sydney, has deposited £1,000 as a bonâ fide for the fulfilment of the contract, and is prepared to commence the work within a month. The route of tramway will begin at the Darling-street wharf and terminate at the municipal boundaries of Balmain and Leichhardt at Callen Park, a distance of about two miles.

Gas versus the Arc Light.—We quote the following paragraph from an interesting letter from the late Sir Charles William Siemens, recently published: "A very powerful arc light gives as much as 33 per cent. of the energy absorbed in the arc as luminous rays (or 25 per cent. measured horizontally), whereas Tyndal found a vivid gas-flame to yield $\frac{1}{25}$th of its radiant energy as luminous. But the $\frac{24}{25}$th is the loss only by invisible rays, and does not include the heat carried up through the chimney as heated air, which loss is not an invariable quantity, but amounts to at least four times the radiant heat. This makes the total heat developed in combustion of the gas $25 \times 4 = 100$ times greater than that sent out in the form of luminous rays.

A Little Ahead of the Times.—In an editorial, the New York *Sun* says that no fewer than four inventors of experience, backed by substantial capital, are striving to perfect systems of electric long-distance rapid transit. The prize is great, and it lies in plain sight. The main idea—namely, that small packages, if not general merchandise and passengers, may be conveyed at a speed varying from 100 to 200 miles an hour—is accepted by practical electricians as sound in theory and easy of application. The difficulties are merely those of detail. True, the difficulties are merely those of detail, but we imagine some considerable time will elapse before those details will work down to practice. One hundred miles an hour is not a very high rate of speed, but we question if 200 miles an hour would be comfortable travelling.

To Indicate Shoals.—An electrical instrument for indicating the presence of shoals has recently been invented. The apparatus consists of a strong cylinder filled with shot, so that when hung by a cable from a ship it will remain perfectly upright in the water. Embedded in its centre is an insulated tube half full of mercury, the two ends being closed by metallic plates, which are in communication, by insulated wires carried by the cable, with an electric battery and bell on the deck of the ship. The action of the apparatus is as follows: When the vessel approaches shallow water the cylinder drags on the ground below, and is consequently no longer upright, but is thrown on its side. This causes the mercury in the tube to touch both the metallic plates attached to that tube, as above explained; the electrical circuit thus becomes complete, and the warning bell on the ship instantly rings.

The Thomson-Houston Electric Railway in Boston.—The following report for April, of the Cambridge Division of the West End Street Railway, Boston, Mass., is of interest, and shows that the electric railway can be depended upon. This road has a previous record of but nine trips lost out of 1,179.

Average number of motors in daily service	8
Round trips of motor cars	2,720
Time in service, motor cars	3,232 hours.
Mileage of motor cars	17,680 miles.
Round trips, one tow car	2,720
Round trips, two tow cars	226
Time in service, towed cars	3,500 hours 30 mins.
Mileage of towed cars	19,149 miles.
Total round trips	5,666
Total car mileage	36,829

Of the above round trips but seven were lost.

Royal Meteorological Society.—At the ordinary meeting of this society, to be held by permission of the Council of the Institution of Civil Engineers at 25, Great George-street, Westminster, on Wednesday, the 19th inst., at 7 p.m., the following papers will be read: "The Climate of British North Borneo," by Robert H. Scott, M.A., F.R.S.; "On the Variation of the Temperature of the Air in England during the period 1849 to 1888," by William Ellis, F.R.A.S., F.R.M.S.; "Atlantic Weather and Rapid Steamship Navigation," by Charles Harding, F.R.M.S.; "Meteorological Phenomena observed during 1875-87 in the neighbourhood of Chelmsford," by Henry Corder; "Rainfall in China, and Meteorological Observations made at Ichang and South Cape in 1888," by W. Dorberck, Ph.D., F.R.M.S. In addition to the above papers, Mr. Marriott will make a communication on the recent thunderstorms, and a number of photographs of lightning will be exhibited.

Bichromate Batteries.—From some late experiments with bichromate cells without diaphragms it has been concluded that a useful form is that where the cells have a height greater than their diameter, and contain about six litres of a solution of 12 parts of bichromate of sodium in 100 parts of water, to which 25 parts of sulphuric acid has been added. If one square dm. of zinc is exposed to the solution, it will not need to be changed for two hours. Owing to their very low internal resistance, these cells can be conveniently used for working glow lamps coupled in parallel. On account of the small quantity of material required, the difficulty of crystallisation, and the low price of the material, the bichromate of sodium is to be preferred to the potassium salt or to chromic acid. The depolarisation and E.M.F. is greater with porous carbon than with hard close-grained carbon. The zincs used should be free from carbon and iron, since, if the cells are coupled in parallel, local action may be set up.

Electric Lighting in Paris.—The Société Popp has finished the installation of the light in the main boulevards. The Thomson-Houston arcs, to the number of 44, are placed 40 metres apart, and are supplied by a Thomson-Houston dynamo of 2,500 volts and 30 amperes, excited by a Gramme machine. The cables are doubly insulated with indiarubber and guttapercha, and have been encased in lead before being laid in the conduits. The Continental Edison Co. are nearing the completion of their section, but the lamps (38 Pilsen arcs) are said to be very ugly. Edison dynamos are of course used, and these

Digitized by Google

are driven by engines of 1,300h.p.; steam being supplied from four Babcock and Wilcox boilers and four Belleville generators. The Electrical Society for the Transmission of Power will furnish the lighting on the boulevard from the Porte St. Denis to the Place de la République. They have arranged a station with four 200-h.p. engines supplying 25 arc lamps. A sum of 200,000f. is to be allowed to the three companies for the lighting of the boulevards, or at the rate of about 50,000f. per kilometre per annum.

Gaselectrics.—We formally lay claim to the invention of this word, a word which is every day becoming more necessary as the definition of a mixed industry. Gaselectrics is that branch of commerce which formerly relied for its returns upon gas, but which has now weakened, and sought to prop itself with the electric fluid. We do not anticipate more than an ephemeral existence for our bantling. In the natural order of things it will lose its first syllable, and we don't care how soon the dismemberment commences. Gaselectrics is just now in full swing in Paris. La Société Technique de l'Industrie du Gaz en France is holding its annual congress. Here is a specimen of the programme: On Wednesday M. Monnier discoursed upon "electric mains, and a visit to the central electric lighting station in the Palais Royal." On Thursday M. Lechatelier took as his subject "Pyrometrical Apparatus"; M. Hospitalier reviewed "Electric Meters," and the morning of the 15th will be devoted to an inspection of the electrical section of the exhibition. Among the papers already announced to be read are a number dealing with electrotechnics.

Leeds.—A correspondent of the *Leeds Mercury* thinks that the Electric Lighting Committee should not be blamed for the delay in deciding what they shall recommend to the Town Council, for the reason that until the last two years central station lighting has not in this country been a very marked success. "I am satisfied," says the correspondent, "looking at the names of the gentlemen on the Lighting Committee, that they will bring a common-sense business view to bear on this subject, and after taking care to inform themselves thoroughly of what are the most successful installations, will recommend what in the interests of true economy (taking efficiency and cost together into consideration) will be the best for the town. I was told the other day that the Brighton installation had been running for several years without a single breakdown, and probably there are other cases in which an equally good record can be given. Now, we have waited so long, and the committee are understood to be prepared to report, I should hope that the Council will not delay the carrying out of their recommendations as quickly as possible, or else the winter will be upon us again before anything is done."

Electrical Plumbing.—The extensive adoption of lead-coated cables for subway electrical lines has given birth to an occupation which is in some sense a new trade—the electrical plumber. The subway cables have to be joined at frequent intervals, at the least at every second manhole. In uniting the ends, the skill of both electric lineman and plumber is required. A cable may contain a hundred or more wires, which may be grouped in pairs to add to the complexity. To join such a cable the wires have to be properly connected with each other, each splice has to be carefully insulated with tape or equivalent wrapping, and finally a sleeve is slipped over the joint and secured by two wiped joints. At this point the lineman has to change his trade and become a plumber, when he "wipes" the joints at each end of the sleeve, so as to protect the wires perfectly from moisture. Much other work falls within his scope. Lateral connections have to be made. One or more wires have to be picked out and led to one side or the other on new routes. As the system grows in extent, so will his work increase in complexity. In fact, what is to some extent a new trade has been created.

Birmingham Electrical and Industrial Exhibition.—We hear that the space for the exhibits in the International Electrical and Industrial Exhibition, to be held in Bingley Hall this year, has all been taken up, and that the preliminary arrangements have been settled in a most satisfactory manner. The original dynamo, or electro-depositing machine, which will be shown in the exhibition, was invented by a Birmingham man, and built in the works of Messrs. Prime and Sons, the well-known electroplaters. An interesting collection of electric lighting apparatus, including one of the early incandescent lamps, is being sent over by Dr. Woodward, of Toronto, who was born in Birmingham. It is said that Dr. Woodward's inventions were sold to Mr. Edison at the time he commenced to bring out the system of lighting which has since become so popular. The contract for erecting the boilers, engines, and other foundations, the orchestra, and the general works connected with transforming Bingley Hall into a fitting home for the exhibition, has been let to Mr. John Parkes, Conybere-street, and the works will be pushed forward with all possible despatch. It is intended to open the exhibition on Thursday, August 1, and arrangements have been made with the leading railway companies in the kingdom to run excursion trains at frequent intervals, to give an opportunity for people at a distance to visit the exhibition at a low charge.

Electric Traction.—The city of Newburyport, Mass., is to have an electric street railway. Similar enterprises are on hand for Pittsburg. St. Louis has also applied for an electrical railway franchise, and the Decatur, Ill., road is now being equipped. A notice from Pierce City, Mo., states that it has become evident to all street railway men that animal power has had its day. A director of the Metropolitan Street Railway Company, which operates more than half the street railway mileage in Pierce City, said that before their last cable line was half completed the Board regretted its decision, and was sorry it had not awaited developments in electricity. The company have let a contract to equip two miles of one of their horse car lines with electricity, and will thoroughly test the system. The line between Beverly and Danvers will probably be finished by the 15th proximo. The Colerain road near Cincinnati will also be opened on the same day. The contracts for the construction of the Alameda-avenue electric railway in Denver, Col., were recently signed by the Thomson-Houston Electric Company, and grading will be commenced at once. The cost of constructing the entire road, which is three and a half miles long, will be 40,000dols. The agreement calls for the line to be in working order by August 15th. Other reports from America are equally satisfactory, but it would take up too much space to enumerate them in detail.

Reading.—At a meeting of the Reading Town Council held on the 6th inst. it was proposed and carried, "That it is advisable that arrangements should be made as soon as practicable for lighting by electricity throughout the whole night such a district as it may be possible to light

satisfactorily with 30 electric lamps, and that the Highways, Streets, and Public Lights and Gas Committee be authorised, subject to the approval of the Council, to arrange with Messrs. Laing, Wharton, and Down, the electrical engineers, accordingly." Mr. Dodd, the proposer of the resolution, said that the sooner they took the question of electric lighting into consideration the better. He had formed the opinion that the electric light recently shown in the town was very desirable indeed for public lighting, and also that its quality was steady and bright, the only fault he could find being that the lamps were hung rather too high. Messrs. Laing, Wharton, and Down's estimate of the cost was based upon the gas lighting being exactly as it was at the present time. If they raised the burners to 5ft., the expense of the two systems would be about the same. The real question was whether the town should be lighted as it had been in past years, or whether they thought this new light, which was becoming universally used in America and all over Europe, and which was to be the light of the future, should be introduced into Reading, while not altogether displacing the gas company.

Utilisation of Electrical Energy in Hungary.—Three installations recently put down by Ganz and Co., of Buda-Pesth, are, owing to their practical character, of some interest. One is at the paper-mills of Mr. Kapferer, at Wattenser, and consists, briefly, of a turbine of 60 effective h.p., driven by a waterfall, near Innsbruck. The current from the dynamos (E.M.F. 500 volts) is conveyed by aerial lines of a length of 0·62 mile to a motor of 50 effective h.p., which in turn drives the paper-making machinery. The installation in the neighbourhood of Neustadt-Vienne is especially interesting, illustrating, as it does, the simultaneous distribution of electricity for light and power by means of alternating currents. In this instance, also, water power is utilised, and a brewery is supplied with 200 lamps and sufficient power to work the various machines used in the establishment. Two 10 h.p. and one 5 h.p. motors are used. The generator is a Ganz alternate-current dynamo of improved construction (type A), giving 50 kilowatts (25 amperes and 2,000 volts) at 500 revolutions per minute. Each of the 10 h.p. motors runs at 830 revolutions per minute, and the 5 h.p. at 1,250. The distance between the generating dynamo and the motors is about a mile and a half. We believe that this installation was to some extent an experimental one. It has been, it would seem, successful, and Mr. Max Bernd, who claims that this is the first practical application of a system of distribution over long distances, and by the same circuit for both power and light, by the Zipernowski-Deri-Blathy transformers, is to be congratulated. The third installation is at the sawmills of Mr. Glesinger, at Furtschek, near Kremnitz, and is an example of direct distribution for power and light. The lighting consists of 50 incandescent and two arcs differently divided. A motor of 3·5 h.p. serves to revolve a drum, by means of which, and a rope wound upon a drum, a truck runs to and fro between the works and the railway station, carrying loads of cut timber.

Company Promotion or Progress?—Within the last few days we have had the Electric Construction Corporation, Limited, upon whose proceedings we are keeping an eye, and Elmore's Foreign and Colonial Patents Copper Depositing Syndicate, the latter being an outcome of Elmore's Patent Copper Depositing Company, Limited, which was formed a few years ago for the purpose of exploiting Messrs. Elmore's English patents for the manufacture of copper articles direct from rough copper bars. Another scheme on the *tapis* is the Municipal Electric Light and Power Corporation, Limited, particulars of which will be found elsewhere in our columns. Yet another is the amalgamation of the Woodhouse and Rawson Companies, which may be looked for in the course of the next few days. As a matter of fact, the parent Elmore Company and the bantling syndicate are both in the hands of Woodhouse and Rawson, and we hear that outside of this triangular promotion they have other irons in the fire. We are asked to state that the shares of "Elmore's Foreign and Colonial Patents Copper Depositing Syndicate, Limited," have been over-applied for, and now stand at $1\frac{1}{16}$ premium. It seems to us incredible that people should be so foolish as to put their money into a concern of this kind. We should have thought the speculative character of the enterprise would have been apparent to the most casual observer. Let us put the matter clearly. The syndicate is formed, with a capital of £120,000, to retail the foreign and colonial patents (many of which are *only applied for*) to the highest bidder. The prospectus leads us to infer that advantageous offers for these patents have already been received. If that is so —seeing that the sale of patents requires no expenditure of capital—why are Messrs. Woodhouse and Rawson so anxious to give away a good thing? Why ask the public for money? As a matter of fact, we believe that Woodhouse and Rawson bought these patents for £37,250, payable as to £11,000 in cash, whereas they are to receive £110,000 for them from the syndicate. Of this latter amount, £80,000 is payable in cash. Messrs. Woodhouse and Rawson's profit would then be £69,000 in cash, besides £3,750 in shares. No doubt this may be a good and sufficient reason for the formation of the syndicate, but we fail to see how it justifies the demand made upon the public.

The Vestries and Electric Lighting.—On the 5th inst., at their fortnightly meeting, the St. Saviour's Board of Works went into the question of electric lighting. The Clerk laid before the Board a communication from the Board of Trade relative to the provisional orders in respect to electric lighting. The Board intimated that they would be guided to a great extent by the views of the local authorities. Mr. Haggis, C.C., remarked that the matter was very pressing. The provisional orders for the companies were not yet framed, and it was desired to pass them during the present session. The County Council considered the matter on the previous day, and the report of their committee would be forwarded immediately to the Board of Trade. The Board wished to compel the companies to lay mains in certain streets, and it would be as well to act expeditiously in the matter. The matter was referred to the Paving Committee for consideration, with power to act.—At the last meeting of the Rotherhithe Vestry, a letter with regard to the electric light was referred to committee, with the object of selecting streets to be scheduled wherein mains must be laid within a stipulated time.—At the meeting of the Newington Vestry, upon the recommendation of the Works and Sanitary Committee, it was resolved that the Board of Trade be asked to include this parish in the provisional order to be granted to the London Electric Supply Corporation.—At Blackpool, Mr. Councillor Eaves called attention to the paragraph relating to the estimate for gas revenue, etc.,

Digitized by Google

account, and asked whether the estimate provided for two electric lights to the north of the North Pier. Mr. Alderman Hall replied that the estimate was not before the Council. It would be laid before the Finance Committee, with the estimates of other departments, and that would be the time to discuss it.—At the last meeting of the Holborn District Board, a letter was received from the secretary to the Board of Trade stating that the companies supplying electricity in the metropolis should be compelled to lay their mains within a specified time in the list of scheduled streets, and in the determination of this list the Board would be largely guided by the views of the local authorities; therefore they would be glad to receive from them at the earliest opportunity a list of the streets which in their opinion should be scheduled. The communication was referred to the Works Committee for consideration and report.

Reception of and Dinner to Prof. Elihu Thomson.—Among the many men of eminent scientific ability and attainments now visiting this country from the United States, one of the most distinguished must be considered to be Prof. Elihu Thomson, president of the American Institute of Electrical Engineers, member of many other learned societies, and the moving spirit of the Thomson-Houston Electric Company. The close affinity of the Laing, Wharton, and Down Construction Syndicate with the Thomson-Houston Company (its *raison d'etre* being the extension of the Thomson-Houston system of lighting), rendered it natural that they should seek to welcome the professor on his arrival in England, and this welcome took the form of a reception and dinner on Wednesday evening at The Ship Hotel, Greenwich. Colonel Martindale, C.B., late R.E., the chairman of the Finance Committee of the syndicate, occupied the chair, and was supported by Mr. Percy Westmacott, Dr. Merz, and Mr. Crewdson, members of the committee, and by Messrs. Wharton, Down, and Davies, the syndicate's expert managers, and Mr. Warine Martindale, the secretary. Among the guests met to do honour to the professor were: Sir William Thomson, F.R.S., Sir Frederick Abel, C.B.; Profs. George Forbes, John Perry, Silvanus Thompson, Ayrton and Hughes; Captains Candee and Holden; Doctors T. A. Fleming and W. Lant Carpenter; Messrs. J. T. Moulton, Q.C., M.P., R. W. Wallace, J. T. Bottomley, Bellani, A. E. Baines, A. Carey, C. H. Davies, Killingworth Hedges, Musgrave Heaphy, C. H. Gimingham, H. F. Kite, A. Margary, H. G. Massingham, John Moore, J. F. Meech, W. Lake, H. Lake, C. W. Price, C. E. Spagnioletti, J. W. Swan, W. H. Snell, W. Shapton, R. H. Tweddell, J. B. Verity, J. E. Wright. Some others of our leading electricians were unable to accept the syndicate's invitation. The professor was received on his arrival by a few words of welcome from the chairman, who was followed by Sir William Thomson, Sir F. Abel, and Mr. Swan. After a brief reply from the professor, the company proceeded to dinner, to which about 46 sat down. The toasts proposed by the chairman were the "Queen," the "President of the United States," "Prof. Elihu Thomson"; "Prosperity to the Thomson-Houston System," was given by Dr. Merz; and "Our Guests," by Mr. Wharton. The professor returned thanks. Mr. Meech, of the Thomson Houston Company, replied on their behalf; and Mr. Moulton, Q.C., for the guests. The reception and dinner may be taken as an honour justly due to Prof. Elihu Thomson, and as constituting another link in the chain of friendship which is binding ever closer together individuals in the two countries, and thus the two countries themselves.

The Phenomena of Conduction.—Prof. H. A. Rowland remarks: "The invention of the telephone, by which sound is carried from one point to another by means of electrical waves, has forced into prominence the subject of these waves. Furthermore, the use of alternating currents for electric lighting brings into play the same phenomenon. Here, again, the difference between a current of water and a current of electricity is very marked. A sound wave traversing the water in the tube, produces a to-and-fro current of water at any given point. So, in the electrical vibration along a wire, the electricity moves to and fro along it in a manner somewhat similar to the water, but with this difference: the disturbance from the water motion is confined to the tube, and the oscillation of the water is greatest in the centre of the tube, while, in the case of the electric current, the ether around the wire is disturbed and the oscillation of the current is greatest at the surface of the wire and least in its centre. The oscillations in the water take place in the tube without reference to the matter outside the tube, whereas the electric oscillations in the wire are entirely dependent on the surrounding space, and the velocity of the propagation is nearly independent of the nature of the wire, provided only that it is a good conductor. We have, in the case of electrical waves along a wire, a disturbance outside the wire and a current within it, and the equations of Maxwell allow us to calculate these with perfect accuracy and give all the laws with respect to them. We find that the velocity of propagation of the waves along a wire, hung far away from other bodies and made of good conducting material, is that of light, or 185,000 miles per second, but when it is hung near any conducting matter, like the earth, or enclosed in a cable and sunk into the sea, the velocity becomes much less. When hung in space, away from other bodies, it forms, as it were, the core of a system of waves in the ether, the amplitude of the disturbance becoming less and less as we move away from the wire. But the most curious fact is that the electric current penetrates only a short distance into the wire, being mostly confined to the surface, especially where the number of oscillations per second is very great. The electrical waves at the surface of a conductor are thus, in some respects, very similar to the waves on the surface of water. The greatest motion in the latter case is at the surface, while it diminishes as we pass downward, and soon becomes inappreciable. Furthermore, the depth to which the disturbance penetrates into the water increases with increase of the length of the wave, being confined to very near the surface for very short waves. So the disturbance in the copper penetrates deeper as the waves and the time of oscillation are longer, and the disturbance is more nearly confined to the surface as the waves become shorter. Experiments show that the disturbance is almost entirely confined to the surface, for at a depth of only 7mm. the disturbance almost entirely vanishes. There are very many practical applications of these theoretical results for electric currents. The most obvious one is to the case of conductors for the alternating currents used in producing the electric light. We find that when these are larger than about half an inch diameter they should be replaced by a number of conductors less than half an inch diameter, or by strips about a quarter of an inch thick, and of any convenient width."

ELECTROLYSIS OF NICKEL SALTS.

BY ALEXANDER WATT.

(Concluded from page 452.)

When pursuing the electrolysis of solutions of metallic salts, I have frequently observed that mixed solutions of salts formed with the mineral acids and those obtained with the vegetable acids have presented considerable advantages, so far as the character of the deposited metal is concerned. With a view to determine whether such combinations would prove equally advantageous in respect to nickel solutions, the two first experiments following were tried:

39. *Sulphate and Citrate of Nickel.*—To a solution of sulphate of nickel was added, a little at a time, one of citrate of nickel, the object being to ascertain whether the addition of the latter salt would cause the deposited metal to become softer, and therefore more susceptible of being burnished than is generally the case with the metal deposited from the simple sulphate solution. It has often occurred to me that a comparatively soft coating of nickel—one that could be readily burnished, instead of being polished in the usual way—might prove serviceable for some classes of nickel-plated work. In this experiment, the current from three small Daniells in series was used, and after each addition of the citrate salt a freshly-prepared brass plate, as the cathode, was immersed. It was noticed that even when only a small quantity of the citrate had been introduced, the deposited metal appeared somewhat whiter than that obtained from the sulphate alone, while, at the same time, the film retained its brightness, whereas the deposits from the sulphate invariably assume a dull appearance after a short immersion. On further additions of the citrate being given, the character of the deposit still further improved until about $\frac{1}{8}$th part of the citrate of nickel solution had been added, at which point the deposited metal became exceedingly bright and white, much more so, indeed, than is ordinarily the case with nickel deposits, which frequently have a yellowish tinge. On applying a steel burnisher to the various plates coated in the bath referred to, the deposited metal readily became brightened, without severe pressure of the tool; in fact, the metal felt somewhat soft under its influence, and a brilliant polish was obtained with comparative ease. As there are many surfaces in ornamental brasswork which are with difficulty "got at" by even the smallest polishing bobs, a solution that would yield a deposit soft enough to burnish should be useful, and I am disposed to believe that such a solution as I have indicated would answer the purpose aimed at.

40. *Sulphate and Acetate of Nickel.*—To a solution of sulphate of nickel was added, gradually as before, a solution of acetate of nickel, a fresh brass plate being immersed after each addition. The current from three Daniells was used, when a bright and very white film of nickel was promptly obtained, and when a fairly good coating had formed, the deposit was tried with a steel burnisher, which at once brightened the surface without excessive pressure. In this case, as also in the one just recorded, there was very little hydrogen given off at the cathode, but in the present instance there was a rather brisk evolution of gas at the anode. In both experiments the electrode surfaces were about equal, and in each case the deposit occurred on both surfaces of the cathode.

41. *Nickel and Ammonium Sulphates with Citrate of Ammonium.*—A solution of the double sulphates of nickel and ammonium being first prepared, to this was gradually added a concentrated solution of citrate of ammonia. In this experiment it was determined to see whether the solution of ammonia in an organic acid would tend to soften the deposit, and at the same time prevent the metal from assuming the usual dullness after a long immersion. The current from three cells was used, and with this a very bright deposit of a slightly yellow colour was quickly obtained; it was observed that the film retained its brightness for a considerable time, but afterwards turned dull. The deposit was, however, sufficiently soft to yield to the influence of the steel burnisher. There was a moderately brisk evolution of gas at the anode, but only a few bubbles of hydrogen appeared at the cathode, which seemed to remain stationary on the plate. The electrode surfaces were about equal, and the film formed on both sides of the cathode.

42. *Sulphate of Nickel and Tartrate of Ammonium.*—To a solution of sulphate of nickel was added, gradually, one of tartrate of ammonium, and a freshly-prepared plate immersed after each addition. The current from three cells was employed, and a very white and bright deposit of nickel was obtained when about one-ninth part of the tartrate solution had been introduced. The electrode surfaces were about equal. On trying the deposit with a steel burnisher, the metal appeared to be tolerably soft, but scarcely so much so as in some of the instances referred to.

43. *Nitrate of Nickel and Citrate of Ammonium.*—An attempt was made to ascertain if the addition of the ammonium salt would in any degree favour the deposition of nickel from its nitrate solution; but, as this was not the case, the solution, after several modifications and fruitless trials, was cast aside.

44. *Sulphates of Nickel and Sodium.*—To prepare a bath of this combination, a strong solution of sulphate of soda was added, a little at a time, to one of sulphate of nickel, and a clean brass cathode immersed after each addition. The addition of the sodium salt appeared to increase the resistance of the solution, as the deposition with the current of three cells took place rather slowly, and it was found necessary to increase the anode surface. Under these conditions, however, the films of nickel which were obtained were of fairly good colour, but not so white as those obtained from some of the foregoing solutions.

45. *Ferricyanide of Nickel in Ammonia.*—A quantity of ferricyanide of nickel was first prepared by precipitating a solution of sulphate of nickel with ferricyanide of potassium, the precipitate being afterwards well washed. Many attempts were made to obtain solutions of this salt; but it yielded most readily to the solvent action of strong liquid ammonia, with which an orange-coloured solution was soon obtained, which was afterwards moderately diluted with water. The solution, after being filtered, was electrolysed with the current from three cells, when a very prompt deposit of nickel was received upon a brass plate, the colour of which was fairly white.

46. *Benzoate of Nickel.*—A boiling solution of benzoic acid was first obtained, to which was gradually added moist carbonate of nickel, which soon became dissolved, forming a pale green solution. With the current from two cells no deposit of metal took place, so a third cell was connected in the series, when a freshly-prepared plate at once became coated with a bright film of nickel of good colour. After an hour's immersion the deposit was tried with the steel burnisher, when it soon became brightly polished with very moderate pressure of the tool, showing that the metal was tolerably soft for nickel.

47. *Salicylate of Nickel.*—A quantity of salicylic acid was first dissolved in water by boiling, and when all the acid was dissolved, moist carbonate of nickel was added gradually, each portion being allowed to dissolve before the next was added. The nickel carbonate readily dissolved in the hot acid liquor, with brisk evolution of carbonic acid, and a pale green solution was obtained. The solution, while still warm, was electrolysed with the current from three cells, when a white deposit of nickel was received upon a brass plate soon after immersion. In preparing the above solution, it seemed somewhat remarkable that so weak an acid should dissolve the carbonate of nickel so readily—a fact which had also been noticed in respect to lactic acid.

48. *Borate of Nickel.*—According to Brande* borate of nickel is "a pale green insoluble compound, formed by double decomposition." In my own experiments, however, I found that a solution of this salt could be prepared in the following way: A strong solution of boracic acid was first prepared by boiling crystals of the acid in water, and to this solution was gradually added moist hydrated oxide of

* "Manual of Chemistry." By William Thomas Brande, F.R.S., etc., p. 814, vol. i.

Digitized by Google

nickel, which readily dissolved in the acid liquor, forming a pale green solution. When cold, the solution thus obtained was electrolysed with the current from three cells, when a white deposit of nickel slowly formed upon a brass plate, but chiefly on the surface facing the anode. It thus became evident that a soluble borate of nickel can be obtained by the direct action of boracic acid upon oxide of nickel. In many of these electrolytic experiments I have succeeded in obtaining solutions of metals of which I have seen no record elsewhere, and the present instance is one of them.

49. *Ferricyanide of Nickel in Cyanide of Potassium.*—To a strong solution of cyanide of potassium was added, in small portions at a time, moist ferricyanide of nickel, each portion being allowed to dissolve before the next was added. The solution thus obtained was afterwards electrolysed with the current from three cells, but no deposit of nickel could be obtained even when the cathode was briskly agitated in the bath. There was a brisk evolution of gas at both electrodes, and after a short immersion the anode became stained a deep black. A further addition of cyanide was then given, when the anode at once became clean, but there was still no metallic deposit upon the negative plate.

50. *Potassio-Tartrate of Nickel, with Soda added.*—Wernicke* states that from a "solution of the hydrated oxide of nickel, in a mixture of cream of tartar, and a little soda and water, electrolysed by means of a current from two Daniell cells," he obtained a "layer of solid hydrated peroxide of nickel upon the anode." To modify this experiment, a strong and hot solution of bitartrate of potassa was first formed, to which was afterwards added a small quantity of a solution of carbonate of soda. With the current from three cells, a patchy and streaky deposit of nickel of very dark colour was obtained upon a brass plate, but the anode remained perfectly clean.

Deposition of Nickel by simple Immersion.—It has generally been understood that nickel, with one or two exceptions, does not deposit from its solutions upon other metals by the process of simple immersion. Having noticed, however, in the course of these experiments that this metal will deposit—upon zinc more especially—from a greater number of solutions than has hitherto been accepted as probable, I determined to pursue a series of trials in this direction, the results of which are given in the following table A. I may say, however, that from neither of the solutions named would nickel deposit upon copper by simple immersion; while, on the other hand, strips of magnesium readily received a coating of the metal in many of them.

TABLE A.

Nickel Solution.	On Zinc.	On Aluminium.	On Magnesium.
Sulphate	Yellow film of metal with evolution of hydrogen	...	Dark metallic stain.
Sulphate with common salt	Brownish film with H.	...	Same.
Sulphate of nickel and sodium	Yellowish film	...	Same.
Sulphate of nickel and magnesium	Black stain with H	...	...
Ammonio-chloride	Yellow film of metal	Slight film	...
Nickel carbonate in cream of tartar	Slight metallic film	...	...
Ammonio-nitrate	...	Slight film ...	...
Ammonio-sulphate	Yellow film with H	...	...
Chlorides of nickel and sodium	Yellow film with H	...	...
Potassio-tartrate	Same	...	...
Nitrates of nickel and ammonium	Dark stain	...	...
Nickel acetate and ammonia	Brown metallic deposit	...	Metallic stain.
Ammonio-acetate	Prompt yellow film	Same, but slower	...
Oxide in ammonia	Film formed very quickly	...	...
Citrate	Same	...	A stain.
Tartrate	Yellow film	...	Metallic stain.
Carbonate in cyanide	Same very quickly formed	...	...
Lactate	Metallic stain	...	Metallic film.
Acetates of nickel and sodium	Yellow film	..	Metallic film.
Carbonate in sal-ammoniac	Metallic but iridescent film	...	Metallic stain.
Sulphate with potash sulphate	Slight film	...	...
Carbonate in alumina sulphate	Yellow film with H.	...	Ammonia given off freely in gaseous bubbles.
Acetates of nickel and potassium	Yellow film	...	Metallic film.
Cyanide of nickel and potassium	...	Slight film ...	Metallic film.
Sulpho-cyanide	Slight film	Same.	...
Ammonio-citrate	Dark film	Slight.	...
Carbonate in sulphate of ammonia	Iridescent film	...	...
Sulphate with tartrate of ammonia	Yellow film formed promptly	...	...

Respecting the character of the deposits obtained by simple immersion, it was noticed that the nickel obtained upon the various strips of metal, even when in its most perfect metallic condition, was always of a yellow or brownish-yellow colour, and never in a single instance white, or even approximately so. The same peculiarity in the colour of nickel deposits is generally observed when weak currents are used to deposit the metal. Indeed I had noticed this many years ago, before the introduction of the dynamo-electric machine, when the voltaic batteries employed had been long in use, and the dilute sulphuric acid had become saturated with zinc. Under these conditions the deposited nickel had always a disagreeable yellow tinge, and this was only rectified when at my suggestion the batteries were renewed more frequently than had been the custom at the establishment referred to. At this period much of the nickel-plating executed in London and elsewhere had a decided yellow tint, and this became more apparent when compared with nickel-plated goods from the United States and France, which, although not so stoutly coated as was the custom in this country, were remarkable for the extreme whiteness of the nickel upon them. Respecting the differences in the colour of electro-deposited nickel, there is no doubt whatever that a low current produces an indifferent colour in the deposited metal. Besides this, the nature of the electrolyte has also a powerful influence in this direction, as I have endeavoured to show in some of the results obtained, by adding to nickel solutions other liquids which not only influenced the colour of the deposit by rendering it whiter, but also appeared to have a decided effect upon the hardness of the metal. It is quite possible that other modifications besides those suggested may be found advantageous, but it is hoped that amongst those given may be found several that will deserve further trial.

* *Journal* of the Chemical Society, vol. ix., p. 307.

CENTRAL STATION ELECTRIC LIGHTING ON THE CONTINENT.

BY KILLINGWORTH HEDGES, M.I.C.E.

(Author of "Central Station Electric Lighting.")

NO. I.

The progress of electric lighting in France has not, until the last two years, been more rapid than in England, although there has been no Electric Lighting Act with the so-called vexatious clauses to block the way. As in our own country, however, there has been no retrograde movement; where the new illuminant has been established it still remains. The moribund Jablochkoff candle with its variegated flicker has been superseded by the incandescent lamp for interior lighting, and for street work the arc lamps of Gramme, Jasper, and Brush are fairly satisfactory. The principal streets of Marseilles are most effectively lighted by the first system. Brush lamps are employed at Hyères, the installation being worthy of notice in that the electric light is worked by the local

gas company, who find that the cost of maintenance is much less than gas-lamps of similar power. Underground cables are used for both these installations, which are, however, only subsidiary to gas, and it was with some surprise that on visiting the town of St. Tropez, which is some 25 miles from the nearest railway station, one found that the electric light had been successfully used in the streets and in some of the houses for the past eighteen months.

An alternating-current Gramme dynamo is driven by a horizontal condensing engine of 50 h.p., constructed by Berger Andre, of Thann, Alsace. The E.M.F. of the primary is 2,000 volts, and is converted by transformers into 100 volts; there are two lighting circuits, one for the 100 street lamps, and the other for private customers. The primary leads, which are principally of silicium-bronze wire 5mm. diameter, are carried on brackets from the sides of the houses much in the same way as the Government telegraph wires are usually run. The transformers, which are of the Zipernowski type, but manufactured by the Edison Company, Paris, are slung high up from insulated brackets, also fixed to the walls. The transformers are well out of the way, and are protected from the wet by loosely-fitting bell-shaped covers. The secondary wires are led in a similar manner, but under the primary, the 100-volt 16 c.p. lamps being fixed in the existing street lanterns. No inconvenience has been experienced with this overhead system, which at first appears to be somewhat dangerous, especially as naked wires are used throughout the city for all the overhead circuits. The charge made for each 16 c.p. lamp per annum is high, the Municipality paying £3. 3s. and private consumers £3. 8s., which includes the enewal of lamps. In spite of the cost being considerably above the petroleum-lamps, which were formerly used, the electric light is preferred, and a very large number of the inhabitants have asked for a general supply to be afforded to all private houses. The transformer system will, before long, be very largely adopted for the electric lighting of the many small towns which are at present quite inefficiently illuminated by oil-lamps placed in lanterns of a most antiquated type. Many of these towns are within a few miles of one another, so that it is possible to illuminate them all in a group from one central station. This plan has been adopted with success for lighting the towns of Dieulefit, department Drôme, and Valreas, Vaucluse, the distance apart being 18 kilometres; the high-tension primary current from the one central station is carried by ordinary telegraph poles, and is reduced to a working potential of 100 volts by Zipernowski transformers, which are arranged in a similar manner to those at St. Tropez.

The electric light has been recently installed at the casino of Monte Carlo, which in all probability is the only establishment in the world possessing three distinct systems of illumination—namely, oil, gas, and electricity. Oil-lamps were introduced a few years ago after the attempt to blow up the gas main by dynamite with the object of making a raid on the tables. The attempt partially succeeded, as the gas lamps were extinguished by the explosion. To guard against its recurrence each electrolier has oil-lamps as well as the incandescent lamps. Two of 16 c.p. are placed in globes similar to those used for the oil, and it is not easy to identify the method of illumination. In all, there are 1,100 electric lights; 500 are employed on the stage of the theatre, and 328 in the magnificent chandelier which lights the concert hall.

The installation is worked by the staff of the gas works which belong to the Casino. As there was no room for the electrical plant, a site has been acquired, about 500 yards from the rooms, by cutting away the sea cliff, the electric cables being run underground in wooden troughs, which are filled with sand.

Two compound condensing steam-engines of the inverted marine type, constructed by Schneider, of Creusot, supply the power. The steam pressure is 90lb. The three boilers are of the multitubular Cornish pattern, and of these one is kept in reserve. A constant E.M.F. of 110 volts is maintained by the Blathy regulator, which consists of a number of wires of varying lengths, which are raised or lowered out of a mercury cup by means of a balanced solenoid, which is operated by a special return wire connected to the most distant part of the main leads. The resistances are automatically inserted or cut out according to the variation of the E.M.F. In fact, the success of this apparatus is due to its sensibility, which may be said to anticipate the turning out or increasing the number of lamps, and thus controls the output of the dynamo. The current for the magnetisation of the exciting dynamo, of course, passes through the resistances. Returning from our visit to the south, *viâ* Italy, one noticed that great progress in street lighting had taken place at Turin in the past year. About 600 arc lamps are used, and the number is to be increased. They are slung on wires stretched across the streets about the height of the windows on the first floor, the conductors are led on insulators on the sides of the houses, except where the squares have to be lighted, when insulated conductors, in wooden troughs, are carried to the base of each standard. To trim the lamps, all of which appeared to be of the Thomson-Houston pattern, a portable balanced ladder is employed, which resembles a short fire-escape, in that it can be elongated at will. Spare lamps and carbons are carried on the truck which forms the base of the ladder, and the apparatus is also used for fixing the insulators in the walls and running the wires. There seems to be no special objection to this plan of fixed lamps, as the trimming is carried out in the early morning. Any inconvenience is fully compensated by the quality of the illumination, which is far superior to that from lamps placed at intervals at the sides of the streets.

Arc lighting is also used for interior work and is far superior to what we have been accustomed to here—it would be difficult to find a better lighted restaurant than that at the Turin railway station. The method was first adopted on account of the cost, which is less than gas, and has not been changed, although there would be no difficulty in obtaining a supply from the Edison central station, which is rapidly extending its system of mains. The Cruto incandescent lamp is manufactured near Turin, and one naturally expected to find it largely adopted, but it was not until the station of Culoz, in France, was reached that any quantity were seen, which appears to bear out the old adage that "a prophet is not honoured in his own country." A great display of electric lighting is to be undertaken by the Municipality of Paris, and the streets were up in all directions for the purpose of running wires, and also making improvements in the roadway and pavements. The promise that, with the opening of the Exhibition, the streets are to resume their gala appearance is now fulfilled, and the flickering "Phare gas-lamps" are relegated to obscurity, where it is hoped they will for ever remain.

ELECTRIC LIGHTING OF LONDON.

Mr. Gisbert Kapp has written the following letter to the *Times* in reply to that of Prof. S. P. Thompson, reprinted in our last issue:

"Electrical engineers will have read with the greatest astonishment the long letter which Prof. Silvanus P. Thompson contributed to your columns on June 1. Major Marindin's report has been received with approval by nearly all who are able to take an unbiased view of the matter, and the verdict both of professional men and of the scientific Press was entirely favourable to his conclusions. Broadly speaking, therefore, the electrical industries are satisfied with the result of the enquiry, and all they now desire is to get to work as soon as possible. There is, however, one company which is very dissatisfied with Major Marindin's report, and its cause is now championed by Prof. Thompson, who would have your readers believe that the system of supply which would have been adopted by this company (the Electric Power Storage Company) is the only absolutely safe one, whilst the system of its two successful rivals, the London and Metropolitan Companies, are insecure because a whole district served by them might be suddenly plunged into darkness through the 'mere derangement of an engine or boiler.' This sounds very alarming, but the experience of the last six or seven years in American and European electric

light stations has shown that, although the continuity of the light depends upon moving machinery, there has hardly ever been a case where a district was plunged into darkness. In some stations the current has not been off the mains for even a minute during a period of several years, and we may therefore conclude that the risk of interruption of current is really infinitesimal. Those who talk so glibly about the advantage of storage over direct supply seem to take it for granted that boilers, engines, and dynamos must sooner or later break down, but that storage cells will never break down. This is absurd, and I think even Prof. Thompson will admit that a 'mere derangement' in a storage battery (say, the breaking of a glass cell and escape of the acid) or a derangement in the intricate and delicate control mechanism required in connection with such batteries will plunge a district into darkness. Thus far there is little difference between the two systems, for either can be made practically safe, but there is a great deal of difference as regards their commercial aspects. Roughly speaking, we may take it that the equipment of a central station on the plan advocated by the Power Storage Company will cost twice, or perhaps three times, as much as an equally efficient station on the alternate-current and transformer system, and, as depreciation and interest on capital expenditure have to be paid out of the earnings, in either case it is clear that the storage system will have a hard struggle to compete on equal terms against the transformer system. The advocates of the former, although they admit the greater capital expenditure, are always asserting that the working expenses will be so much less. This may or may not be the case, but up to the present the point has not been practically demonstrated, and the great alarm shown by the storage companies on account of the incursions of the transformer companies into their own special districts tends to show that they are, after all, not so very confident as to their ability to work the system cheaply.

"It is amusing to note the complete change of front in the argument as regards monopolies which underlies Prof. Thompson's letter. During the enquiry the storage companies laid great stress on the fact that 'districting' would not confer upon any company an exclusive monopoly, because there was always the possibility of a revocation of the order if they did not do their work well, and the potential competition of another company who might be able and willing to do the work better. No, they did not ask for a monopoly; they simply wanted a fair opportunity of doing good work. Well, with the exception of the one company already mentioned, all the other storage companies have obtained what they wanted. Yet they are not satisfied, and Prof. Thompson now says that if the Board of Trade were to adopt the recommendations of Major Marindin it would hand over 'nine-tenths of the allotted districts to the exclusive control of either the Metropolitan Electric Company or of the London Electric Supply Corporation.' Now this is a very misleading statement. If the storage companies only ask for one-tenth of the area (taking care to pick out the most promising districts), and get it, is that any reason why the other nine-tenths should be refused to their competitors? Clearly not. The alternate-current companies are ready to serve the remunerative as well as the less remunerative districts, and by their system they are able to do this on a sound commercial basis. They have no monopoly, and do not object to storage companies coming into their districts, knowing perfectly well that they will easily be able to hold their own. A great deal has been said as to the inability of the alternate-current companies to supply motive power. I do not admit this inability, and Prof. Thompson himself must know that mechanical energy can be obtained from an alternating current, for he has seen it done as well as I; but the importance of the power business has been greatly over-estimated. Let anyone make a house-to-house canvas in the West End to find out how much light and how much power the several householders would take, and he will see that light is the commodity immediately in request, whilst very few will care to take power. In other parts of the town the proportion may be reversed, but that is no reason why we should not give to the private householder that what he most wants—namely, light."

CORRESPONDENCE.

LIGHTNING CONDUCTORS.

To the Editor of The Electrical Engineer.

Sir,—I scarcely feel certain as to whether you feel any interest in the question of lightning-conductors, so far as they regard the safety of your own personal friends.

I know, of course, that you take a deep interest in the *science* of this moderately important question. But it has become to me and my friends a very important question, and I ask, most humbly, your advice how you consider I should proceed to obtain safety under the following circumstances:

I have taken an unfurnished room at 59, Dalston-lane. It is a charming old house, with strong built walls and splendid doors, with at least six bolts to every door. So far so good. But our next door neighbour on the "port hand," looking towards the road, is St. Bartholomew's Church.

Now, St. Bartholomew's Church is (I wish you to understand) so absolutely next door that the windows look out into my landlord's garden. We can hear every note of the organ, and nearly all the choir, except when they sing *pianissimo*. I only mention this to describe to you how close I am situated to St. Bartholomew's.

Perhaps you may recollect that we have had some thunderstorms lately. They were not very near here, as the least I could count, between flash and crash, was five (counting fairly and truly to the best of my ability), and so I believe, making the storm five miles away.

But the next thunderstorm may come nearer (and they seem "fooling around") and then, if you will only listen to me one second, I will tell you my troubles. They are as follows:

Our house is only two storeys high, probably twenty-five feet. Now, I estimate the church as sixty or seventy feet high. It is a long barn-like building, about one hundred and twenty feet long, with a steep slope to its roof, and a stone cross at each gable end. I have looked in vain for any sign of a lightning-conductor, and cannot see one. It is possible that it is concealed *inside* the church. But the house I live in is evidently many years older than the church, and the church has been added on to the house; the church, as far as atmospheric electrical effects are concerned, rules the safety of this house.

I have, at the risk of wearying your readers, given you a brief summary of the condition of St. Bartholomew's Church, Dalston, and 59, Dalston-lane, and I humbly ask you, Mr. Editor, whether you can kindly give me advice on the following queries which have arisen in my head, night and day (particularly when the last thunderstorm was on), as to regards how it is possible to make anybody responsible for the safety of this house and its inmates in time for the next "electrical atmospheric disturbance" (I believe that is the proper term):

Firstly.—Ought there not to be a proper system of lightning-conductors to the church, with no sham earth connections?

Secondly.—Supposing that there ought to be such system, of which I think you will have little doubt, who is responsible for the cost, or to insist that the work shall be executed?

Thirdly.—Can any person, or body of persons, corporate or not, erect with impunity and with no responsibility, a building next to another (previously constructed) which new building becomes, when unsupplied with proper lightning-conductors, a danger to the older building?

These three questions may be of importance to more persons than merely to myself and friends, and I therefore ask you in the interest of the public to print this letter in your valuable journal in order to ventilate the question.

If you can kindly find room therefore for my letter, and give me also some advice on the subject, I shall be very greatly obliged.—Yours, etc.,

F. C. Webb, M.I.C.E.

59, Dalston-lane, N.E., June 11, 1889.

THE

ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence ; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

Communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

Although the Paris Exhibition is open, the major portion of the exhibits are in so backward a state that any systematic description is almost impossible at present, so we shall wait a short time till the chaos of packing cases becomes a neat arrangement of exhibits. It is needless to tell our readers that—so far as our description of the electrical exhibits is concerned—our attention will, in the first place, be directed to the interests of English and American exhibitors. A special edition of this paper, with the report of the exhibition in two languages—English and French—will be obtainable in the Exhibition.

ELECTRICITY IN AID OF STEAM POWER.

If Ireland is to enter upon a more active history of the kind that has marked the progress of Great Britain, there is no doubt that it must be much on the same lines, or must be due to similar causes, namely, activity in manufactures of different kinds. In England and in Scotland manufactures owe much to cheap power. In many parts of Ireland steam power may not be so cheaply obtainable, but by the aid of electricity the power which Nature has placed in her possession may be in many places made subservient to the requirements of manufactures which might be carried on at a profit in the Green Isle.

So much is now being proposed as means of encouraging trade and agriculture in that country through the medium of railway and other transport facilities, and by drainage works, that it might possibly be said that further proposals are at present quite unnecessary. If, however, feeder railways are to be made, it may be urged that something more than agricultural development may be served by them. Manufactures of several kinds which we need not specify might be encouraged, and cheap power in suitable localities would become one of the first aids to development in that direction. As is well known, there are in numerous parts of Ireland some splendid sources of water power. They are, however, most of them situated at distances from the centres of population, or from the existing ports or railways. Electricity should, to a great extent, remove this difficulty, and the construction of light railways should do a great deal more.

It has been calculated,* on satisfactory data, that there is at least a million horse-power, more or less, available in different parts of Ireland, taking the whole year round, the availability depending not on the quantity of water running to the sea, but upon suitability of the sites at which the power could be realised for manufacturing purposes. This qualification puts an enormous proportion of the whole available supply beyond the reach of commercial application, so long as it is essential that the manufactory or mill must be placed, as in the old days of water-power application, on the site of the waterfall. This, however, is no longer a prime necessity. With the cheap means of power transmission which the modern generator and motor, and we may also say the modern turbine, have placed in our possession, many of the sources of power hitherto unavailable may be brought into requisition.

Within a radius of ten or fifteen miles of some of the largest waterfalls there are many suitable sites for the establishment of mills or manufactories, and by means of high tension currents the power derivable from these water supplies might be transmitted, not simply to one or two very large establish-

* Kane's "Industrial Resources of Ireland.

Digitized by Google

ments, but to numerous small mills, and in this way the minor capitalist manufacturer would have the means which the cost of steam power at present places beyond his reach. Even if an extravagant reduction be made in the water power theoretically available, there is vastly more practically at hand than could by any means be employed in Ireland for a great many years, in most eligible positions. At Bandon, Cork, Killarney, Clonmel, Waterford, Wexford, and Limerick in the south, amongst others, there is not less than 40,000 h.p. obtainable in places from which the power could be electrically transmitted to large and small consumers. On the Shannon, within twelve miles of Limerick, there is a fall of 97ft., and a sudden fall within a short length of that big river of upwards of 21ft. Here with practicable works not less than 14,000 h.p. could be obtained. Proceeding northward, it will be found that Lough Corrib and Lough Mask discharge into the sea at Galway with a fall of 13ft., affording an easily available 1,300 h.p. Where Lough Mask discharges into Lough Corrib a fall of 36ft. exists, and at least as much power as that last mentioned is to be had. This is about twenty-one miles from Galway, and lake navigation is available. Further north there is at least 1,800 h.p. running to waste at Ballyshannon, and this is within twenty miles of Sligo port. At Belleek is again a large supply, and at numerous places further north, including Lough Neagh and Coleraine. It is quite unnecessary to give a list of the large number of places at which from one to several hundred horse-power could be utilised. It is not, however, applicable where it is, and we purpose only in this article to direct attention to the possibility of making it useful by means of electric transmission, for not only ought it to be made available in this way for manufacturing purposes, but also for the many purposes to which even in existing towns in Ireland power distribution to large and small consumers might be made a source of industrial development.

THE LIMIT OF SPEAKING ON TELEPHONE LINES.

BY DR. V. WIETLISBACH, OF BERN.

The most important electrical properties of a line are its resistance, capacity, induction, and insulation. A perfectly accurate theory would also have to take into account the polarisation of the dielectric employed for insulation and the magnetisation of the material of which the lines consist. And, further, we have to take into consideration the fact that the very rapidly undulating telephonic currents do not uniformly utilise the whole cross-section of the wire, but chiefly circulate on its surface. Sir W. Thomson has calculated that a current of 150 waves per second only penetrates to a depth of 3mm. into the wire, so that the largest useful cross-section would amount to 6mm. If we wish to make use of larger cross-sections, we must give to the conductors the form of hollow tubes or flat ribbons, in order to avoid waste of conducting material. Telephonic currents generally are even more rapid, and the useful cross-section is therefore reduced to 4·5mm. For this reason so-called compound wires have lately been used for long lines, consisting of a copper tube with an iron or steel core.

In addition to these requirements, which can be clearly defined from a technical point of view, numerous other questions have to be considered in telephony, such as the nature and sensitiveness of the apparatus, the greater or less aptitude of the voice and the ear of the persons conversing, so that it is quite impossible to determine in a general and accurate manner the distance to which speaking is possible. In spite of this, we find articles published continually which treat of this subject. From a theoretical point of view, one can speak to any distance. One has only to bring apparatus and lines in agreement with one another and with the desired distance. Similar conditions prevail here as with the telegraph. If a Morse apparatus has to be worked at a short distance, one single element is sufficient. For longer distances, up to about 100km., an iron wire of three millimetres and a battery of 50 elements are employed. On long direct lines—for instance, Berlin, Rome, Vienna, Constantinople—a wire of 5·6mm. and several hundred elements or a powerful dynamo are used. On long submarine cables these strong currents must not be employed, because they would quickly destroy the insulation. In this case we are restricted to the use of extremely sensitive apparatus, which can be worked securely even with minimum currents. Thus the telegraph adapts itself, by convenient arrangements of line, apparatus, and current, to any distance whatever. The longer the distance the more complicated the arrangements, and the more costly the installations; but this is the only reason which forbids the employment of very long lines. On the other hand, an installation which is calculated for a line of 100km. is not fitted to work on a line of 1,000km.

In like manner we can by improving the line, and by strengthening the transmitter and the sensitiveness of the receiver, telephone to any distance. The most essential point in this case, too, is the convenient arrangement of the different accessories, which, it cannot be denied, is a more difficult matter than in the case of the telegraph, for the simple reason that a good telephonic transmission requires much greater care in the construction of the line. That the clearness of transmission depends much more on the proper arrangement of the various accessories is proved in the most characteristic manner by the evidence of a New York subscriber, who complains that he has the greatest difficulty possible in understanding another New York subscriber, while he can converse with a Boston subscriber (a distance of 250 miles) as easily as if he were in the same room.

Mr. Preece has had the unfortunate idea to apply a formula which Sir W. Thomson has given for cable telegraphy to telephone lines, and the formula possessing such weighty credentials has found numerous successors. The formula in question is

$$t = \frac{130,000,000}{l^2 \mathrm{K R}},$$

where t expresses how many times per minute the word "Paris" can be telegraphed through the cables, l length of the cable, K capacity, and R resistance per km. The correctness of the formula for the purposes and the circumstances under which it was deduced cannot be doubted, but the manner in which it is proposed to use it for telephone lines is an entirely erroneous one. We have at the outset spoken of four electric properties which characterise a line; Thomson's formula only contains two—capacity and resistance. This is easily explained by the fact that Thomson in deducing the formula has telegraph cables exclusively in his view These are generally insulated with guttapercha; their insulation is therefore always the same, and, what is more, relatively very high. The line always consists of copper strands, and the induction is consequently very small. Even under these simple conditions the formula is not absolutely correct, but it suffices for the purpose it has to serve—namely, to calculate in cables of uniform make the most favourable cross-section at a definite speed of transmission.

In cable telegraphy the cable is charged at one end, and then again discharged. By the combination of individual

Digitized by Google

charges and discharges of different length and unequally rapid succession, the cablegram is obtained. In consequence of the great length and the large capacity of the cable the manipulations of the transmitter are not instantaneously transmitted to the other end of the cable, but a certain time elapses between the sending and the receipt of the signals. If now the transmitter is manipulated too quickly, the charging and discharging currents are mixed at the terminal station, and the receiver executes movements which in no way correspond to those of the sending key; so, for instance, a long depression of the key can be changed into a short interval by the discharge current of the previous signal, or a short interval between two depressions of the key into a long one. Thomson's formula determines the rate of speed at which the key ought to be manipulated in order to receive at a given charging capacity of the cable correct signals at the receiving end. Thomson's formula, therefore, refers to G. P. cables, immersed in the sea, traversed by charge and discharge currents, and operated with a syphon recorder, or some such sensitive receiver. And now it is proposed to apply this formula to lines through which currents are circulating, which have not the least resemblance with those employed in cable telegraphy, to apply it for the determination of something about which nobody has any clear conception. That this vagueness is not on the side of those who disapprove of the misapplication of the formula is shown by the statements of those authors who have made use of this formula, and which are contained in the following table:

If we write Thomson's formula in the form

$$A = l^2 K R,$$

A has the following maximum values, l being expressed in km., K in microfarads, and R in ohms.

	Preece.	Jacques.	Madsen.	Wietlisbach.	Line, Chicago-New York.
Copper overhead	15,000	2,000-4,500	3,000	—	Over 50,000
Cable	12,000	2,000-4,500	3,000	1,000	Less than 5,000
Iron overhead ...	10,000	2,000-4,500	6,000	—	—

I leave it to the reader to draw his own conclusions from this table.

The product, capacity, into resistance, which is determined by Thomson's formula is certainly a measure of the efficiency of telephone cables. The smaller this product the better the cable for telephonic purposes, and for single-wire cables of uniform make the distance of speaking may be approximately determined. But this determination becomes impossible as soon as cables of different make, whose insulating materials are differently affected by polarisation, are to be compared with one another, or as soon as the cable no longer forms the sole constituent of the line.

If we consult experience we find that telephoning is possible.

On overhead copper wire to a distance 2,000km.
On iron wire „ „ 300km.
On single-wire cables „ „ 10km.
On double-wire cables not determined.

The latter distance entirely depends on the construction of the cable, and may certainly exceed 100km.

If on most of the lines these long distances are not reached, the fault rarely lies in the fact that the product of capacity and resistance is too large, but, provided that faulty apparatus are not responsible for it, the insulation of the line is often insufficient, or the insulating material, especially in cables, is not properly chosen, or the magnetic inertia is too large.

From these considerations we may draw the following conclusions:

1. There does not exist at present any formula or rule from which the limit of speaking distance can be calculated even with approximate accuracy.

2. The attempts made hitherto are not decisive, because they rest on a false basis, or made with a faulty apparatus, so that it was not the line but the apparatus which gave out.

3. On overhead copper lines the distance has not been reached yet at which telephoning is impossible.—*New York Electrical Review.*

SOME RESULTS WITH SECONDARY BATTERIES IN TRAIN LIGHTING.*

BY ALEXANDER S. BROWN.

It is now four years since the Pennsylvania Railroad, appreciating the advantages of electric lighting for train lighting, began a series of experiments with the secondary battery, for the illumination of parlour cars.

I am unable to give the cost of lighting by any of the batteries referred to, as the expense appears to have been a secondary consideration compared with the necessity of securing the best system of illumination.

The first experiments made by the company were with the Faure accumulator, which was brought to this country from France in the spring or early summer of 1882, and put on passenger coach No. 397 in August of that year. The car was run for a few days only, but enough was learned in that time to show that the lighting of cars by secondary batteries was perfectly practicable, when a modified form of the battery could be obtained.

During the summer of 1884 experiments with the Brush storage batteries were commenced at the Altoona shops of the Pennsylvania Railroad, and continued through the fall and winter of that year. These experiments were made by Dr. Dudley, and proved so successful that eight parlour cars, which were being constructed at that time, were equipped for incandescent lighting and put into regular service on April 1, 1885.

The Brush cells used consisted of three plates each, two negative and one positive, the amount of surface of the positive plate being equal to that of both the negatives. These plates differed from those now used, there being no paste in their composition. The negative plate was designed to give the greatest possible amount of surface from the least weight of material. The positive plate measured 8in. by 9in. by 1in. and the negative 8in. by 9in. by ½in.

These batteries are rated at 70 ampere hours, but the hard usage they received soon reduced their capacity, and at the end of a year's time the positive plates were almost entirely destroyed. In fact, I have taken plates out of the cells which had holes in them fully 4in. in diameter, while the deposit in the bottom of the cell would be from 1in. to 1½in. in depth. The plates also had a decided tendency both to buckle and grow, and in a number of cases it was a very difficult matter to remove the plates without injury to the cell. I allude more particularly to the positive plate. The weak points in the Brush battery were the small number of ampere hours per pound of material—about two, I believe. There was a tendency to buckle and sulphate, and the arrangement for connecting the plates was such that there was oxidation at the junction, causing the plates to break when subject to the motion of the car. While using the Brush battery the cars were wired with the battery-boxes, one on each side of the car, coupled together in series, each box holding three trays, and each tray containing four cells, this giving a total of 24 cells to a car, or an E.M.F. of 48 volts. The lamps used originally were of the Brush-Swan type.

After using this style for some time an improved pattern of Brush-Swan lamp was substituted, but the great drawback to this lamp was its frailty, the breakage per day often averaging four per cent. of the total number of lamps in use on all the cars. These lamps required about 45 volts and 1 ampere of current, and each car contained ten lamps, seven in the body, one in the smoking-room and one in each vestibule, thus using about 10 amperes of current, and as the batteries were rated at 70 ampere hours, we should have obtained from six and one-half to seven hours good light, but it was very seldom, after the batteries had been used for a short time, that we could get

* A paper read before the American Institute of Electrical Engineers, New York, May 22, 1889.

Digitized by Google

over five and one-half hours. This could hardly be called economical, for to obtain five or six hours' light we were obliged to charge from 15 to 20 hours with a Brush arc light dynamo giving a current of about 10 amperes. Then taking the weight into consideration, each time the car needed charging, the trays, six in number, and weighing 1,200 pounds, had to be loaded on the truck, pulled over to one side of the car, and the discharged trays taken out and freshly charged ones put in their place. The remaining three were then taken around to the other side of the car and changed in the same manner, which was difficult. During the month of December, 1886, we commenced using one battery of the 7 B type, manufactured by the Electrical Accumulator Company. This battery was a decided improvement over those previously used, giving as it did nearly double the number of ampere hours for the same weight of material. After using the battery for about a year the positive plate began to give way and new ones were substituted, the negatives, however, being retained, they not having deteriorated. In fact, we are still using the negative plates of our original 7 B battery. This battery proved to be so satisfactory that in June, 1887, we added two more of the same type, and two manufactured by the Julien Electric Company. The latter batteries were similar in size and shape to the 7 B type of the Accumulator Company, but did not seem to stand the hard usage so well, as they would crack instead of buckling, and allow a large quantity of the paste to become loosened and fall out. It is proper to state, however, that these plates were made especially for us to fit the cells we were using, and were not of the regular Julien type. After the positive plates of this battery became worthless, and not having any others to put in their place, we decided to make a kind of consolidated affair, and see how Julien negative and Accumulator positive plates would work together. The result was extremely satisfactory, and we have had no trouble with them whatever, excepting the occasional buckling of a positive plate.

During the fall of 1887, we began substituting the Accumulator batteries for the Brush batteries, and by the end of the year we were using them altogether, with the exception of the two Julien I have mentioned. We, however, kept 96 of our best Brush cells, to be used in case of an accident to the incandescent dynamos, which are used to supply the current for the railroad telegraph as well as for lighting the passenger station.

After the change in batteries had been made, it was thought best to change the system of wiring the cars, so that instead of its being necessary to put batteries on each side of the car, we need only put them on one side, and get the same amount of light. This was done by connecting the two boxes under the car in parallel, and substituting 23-volt Edison lamps for our 45-volt Brush-Swan lamps. After doing this we found that we were able to get as many hours' light from 12 cells as we formerly did from 24. Of course this change reduced the expense of lighting the cars considerably, for where we formerly had a change of battery for each car, or 48 cells, we now needed only 24 cells per car, with a few extra ones to be used in case the 12 cells would not be able to supply sufficient light for a long trip. This system of lighting proved so successful that it was decided to substitute it for gas in the remaining seven parlour cars. The wiring of these cars was commenced at the Meadow shops, near Jersey City, last September, and has just been completed. These cars are arranged for the 23 C type of the Accumulator Company's battery, and 19 B type of the Julien battery. The battery-boxes under the cars are larger than the old style, and contain four trays or 16 cells, the lamps we used taking 23 volts E.M.F. Changes were also made the first of the year in the system of charging, and the batteries are now charged from an incandescent dynamo instead of an arc, thus enabling the batteries to be charged with any amount of current desired.

In 1887, the Pullman Palace Car Company commenced using the electric light on one of three trains of the New York and Chicago limited express, and the charging of the batteries at Jersey City was given into the hands of the Pennsylvania Railroad Company. The batteries used were the 7 B type of the Electrical Accumulator Company, 30 cells to a car, and usually there are six cars in the train. These batteries would furnish enough light for one trip, and each time the train arrived at either terminus it was necessary to replace them with freshly charged cells. This was not objectionable at Chicago, for the train arrived there in the morning, so that they could be charged during the day, but in Jersey City, where the train did not arrive until evening, the work was very difficult on account of the dynamo being in use for other purposes. After this one train had been running a short time, another one was fitted up, 19 B type of Julien battery being used. After Mr. Bauer became connected with the Pullman Company, he did away with charging the batteries at the ends of the line, and introduced a Brotherhood engine and Eickemeyer dynamo in the baggage car of each train, in order that the batteries might be charged in transit. When the train leaves Jersey City, the baggage car is on the rear, and consequently no charging is done until it leaves Philadelphia, where the train is reversed, bringing the baggage car next to the locomotive. The batteries are charged continuously until the train reaches Chicago, and the same practice is continued on the return trip. The steam for driving the Brotherhood engine is taken from the locomotive boiler, and the exhaust is used for heating the train.

So far as the Pennsylvania Railroad is concerned, the electric lighting of passenger trains may be considered an assured success, and leading as it does to the abolition of kerosene-lamps, and incidentally encouraging the adoption of steam heating, the safety and comfort of the passenger is certainly increased.

THE MEASUREMENT OF THE CANDLE-POWER OF ELECTRIC STREET LIGHTS.

BY PROFESSOR STODDARD.

In measuring the candle-power of electric street lights while burning in their position on the street, one has certain difficulties to contend with which are absent in ordinary photometric measurements. The chief of these difficulties lies in the facts that the lamp to be tested is at a considerable height above the horizontal plane which the photometer can, in most cases, conveniently occupy, and that the work must be done out of doors. In compliance with the request of the editor of the *Journal*, I will briefly describe the way in which I have sought to solve the problem which presents itself.

In the first place, the photometer must be modified, so that the light coming from a point considerably above its plane shall yield a beam parallel to the bar. This may be done in two ways :

First.—By having the photometer bar horizontal, as usual, and placing at one end of it a reflector, which shall throw the beam from the electric light along the bar. This reflector must, of course, be a plane surface, and may be an ordinary mirror or a totally reflecting prism.

Second.—By inclining the bar in the vertical plane so that it shall point directly at the lamp. Of these two methods I prefer the latter, because the use of a reflector of any sort involves loss of some light, the amount of which must be carefully determined and introduced as a correction in the final calculation, while it offers no advantage over the direct method to compensate for the greater trouble and liability of error in the results.

In the second place, a direct measurement of the distance from the arc to the Bunsen screen is, in general, not easy, and the modified photometer should provide some way for its indirect and, at the same time, accurate determination.

Thirdly, the photometric work must be done in the open air, and in a number of more or less widely separated places on the same evening. The photometer must, consequently, be readily portable, and at the same time must be provided with a special lantern to protect the standard light from draughts, and with screens to cut off all extraneous light.

To meet these points I have constructed my photometer as follows : The graduated bar is fastened by a pin passing through one end to the edge of a thick board which serves as the base of the instrument. On this pin it moves freely

Digitized by Google

in a vertical plane. At a convenient distance from the pivoted end a graduated circular arc, of some 50deg., is attached to it in such a position that when the bar is raised, the arc plays in a slot in the edge of the base board. By means of a thumb-screw the arc can be clamped to the base at any point, and thus serve both as a support for the bar at any angle above the base and as a means for determining this angle by the reading of the graduation. The base has fastened to it a carefully adjusted level. The lantern containing the standard light is mounted on the base just beyond the pivoted end of the bar. When a measurement is to be made, the photometer is first brought into the same vertical plane with the electric lamp, and the base accurately levelled. The bar is then raised until it points directly at the lamp, and clamped in this position. The carrier, with its Bunsen screen, is then mounted on the bar together with blackened diaphragms, which serve to cut off all light except that coming from the standard and the lamp to be tested. If the night is a dark one, and other lights not too near, no further precautions in the way of screens are necessary; otherwise, the photometer is mounted in a covered wagon.

After the readings have been made [giving the distances of the Bunsen screen from the zero mark at the pivoted end of the bar], the horizontal distance from the zero mark to a point vertically beneath the electric light is measured, and the angular elevation of the photometer bar is read on the graduated arc. From these data the direct distances from the screen to the electric light are readily calculated. The corresponding distances from the screen to the standard are obtained afterward by placing the bar at the angle noted and measuring directly from the screen [at its reading] to the point which the standard occupied in the out-door work.—*American Gas Light Journal.*

THE LIGHTING OF THE CITY OF DUBLIN.

On the 6th inst. Major F. A. Marindin, R.E., sat in Dublin to hear an application by the Alliance and Consumers' Gas Company for permission to open certain streets in the city for the purpose of laying electric lighting cables for lighting of private houses. The streets proposed to be opened were: Nassau-street, Grafton-street, Kildare-street, Dawson-street, Merrion-square, W., Upper Merrion-street, Anne-street, Duke-street, Frederick-street, and Molesworth-street. The gas company contended that under their Acts of Parliament they required no license and no other permission than the one they sought. The Corporation opposed the application.

Major Marindin said this enquiry was of a novel character. The ordinary enquiry was where a company was seeking by means of a provisional order to get power to supply electricity or water where the local authority withheld its consent. In this case the company was moving the Board of Trade to exercise certain powers which they said they had under their Acts, but he should treat it as if it were an ordinary case, and ask the gas company to give him any reasons they could why the Board of Trade should exercise those powers. Of course, he had nothing to do with the legal interpretations of these sections.

Mr. George Wright said he would open the case for the gas company very briefly. The Act of 1866 was the one by which the Alliance and Dublin Consumers' Gas Company was formed for the purpose of "making and supplying gas and other improved means of lighting for public and private purposes"; and certainly, having regard to the fact that electricity was at that time, though not used, well known as a light much talked of and looked forward to, it had always been maintained by the company that under that they had the power of supplying electric light. That was the fifth section. The sixth section limited the area within which the company could supply this light to the whole of the Metropolitan Police District, a number of townships adjoining Dublin, 13 altogether, and the township of Bray and Powerscourt, in the county Wicklow. In 1883 the company went to Parliament to get powers to raise a capital of £286,000. About that time the company purchased the plant of the Dublin Electric Lighting Company, and had since been supplying light to a number of firms in the city, their right to do so never having been questioned. It had been supplied by overhead wires, but to that system there were many obvious objections, and it was necessary that the company should have power to open up the streets and lay them underground. Under the Act of 1866 and other Acts, the gas company had power to open the streets for all the purposes of their Acts; while the streets were closed by the Corporation and the expenses charged to the company; and if the legal position of the company was right, that they had the power to supply electric light also, it would follow, and they had been so advised by eminent counsel, that they had the same power, or at all events up to the Act of 1883, to open up the streets for the purpose of laying these electric wires. By the Act of 1883 a certain restriction was imposed on them which made this enquiry necessary. That restriction did not take away from them the power to open up the streets, but said that they should not be at liberty to do so without the permission of the Board of Trade, who might impose such conditions for the public safety as to them might seem reasonable. The Corporation of Dublin had already got a license for public lighting, and had power to open the streets wherever they liked, and the gas company only asked the same permission for private lighting. The scheme the company brought forward was this. Of old capital there remained £13,000—that was of the capital raised in 1866; that capital was not tied up in any way, not subject to any restrictions, and was now applicable to any scheme of electric lighting that they might devise. They had a former sum of capital under the Act of 1883 of £383,000; that they could not touch without getting the sanction of the Board of Trade, for the 25th section of that Act provided that it should not be applied to the supply of electricity without the sanction of the Board of Trade. It might be that in the future they would ask for that sanction, but in the present application they did not. As to any excess in the present estimate over the £13,000 capital there would be no difficulty about raising it. As to the works themselves, the area was a rather populous, busy, and wealthy part of the town, where there was a very great demand for electric lighting. The Corporation could be only opposing this on one ground, that they wished to get a monopoly of private lighting as they had of public. Monopolies were at all times offensive, and the Act of 1888 apparently condemned monopolies in electric lighting as strongly as anything could. They had had numerous applications from persons living within the proposed area to supply them, but they could not do so at present without risk by the system of overhead wires.

During the further course of the enquiry it was stated that about £3,000 was given for the plant of the Electric Lighting Company, which originally cost some £13,000 or £14,000, and the gas company had since spent £4,000 or £5,000 in providing a new plant.

Mr. Arthur Porte, electrical engineer, explained the scheme of the gas company. In the area proposed to be taken in there were about 600 houses, a large number of public institutions and clubs. They supplied at present with electric lights Pim's, Clery's in O'Connell-street, Wright's, Westmoreland-street; Mitchell's, Grafton-street; Bolton's, North's, Dunne's, the Gaiety Theatre, and Powell's, William-street. Within the last year they had received applications from 34 or 35 separate houses for a supply of the electric light. The scheme would cost from £13,000 to £16,000. The Electric Lighting Company charged 5d. an hour for an arc lamp, the gas company charged 8d., but in one case where they had a large consumer they charged less; for incandescent lights the electric company proposed to charge ½d. an hour, the gas company charged 1d. He had no objection to the Corporation and the gas company operating in the same area.

A number of gentlemen having given evidence in favour of electric lighting, Prof. Forbes, F.R.S., deposed he had examined the scheme prepared by Mr. Porte; he believed the estimate was very closely accurate. The plan was a very good one indeed, and would work very well; it would be a most thorough and satisfactory working of the district, very much more so than one was accustomed to see.

Mr. Walker then opened the case for the Corporation. There was nothing in any Act of the gas company to authorise them to supply electric light without coming to the Board of Trade in the usual way. The Corporation were the local authority for the whole city, and had already obtained a license for public lighting; they intended to proceed and obtain a license for private lighting, and they had unlimited powers of borrowing. Now, what was the position of the gas company? They had exhausted all the capital which might have been applied under the previous Acts—if they were right—to electricity, and they now intended to borow under an Act which prevented them applying any of the money to electricity, and they would put that capital in place of the old. It was an extraordinary proposition that a gas company should, out of the city, pick out this little bit of residential portion and apply a limited capital of £12,000 to it, leaving the less wealthy district to be supplied by the local authority. Would the Board of Trade sanction a scheme which never could go beyond that limited area? Was it to be supposed that the company would run this electric light against the gas supply; and, having on one hand a gas supply yielding 10½, and on the other this novel experiment of electric light, was it not obvious that their object was to smother the electric light in its cradle? He submitted that the application was wholly illegal, and should be refused.

A variety of evidence having been offered, Major Marindin said he would make his report to the Board of Trade in due course, and the proceedings terminated.

ALTERNATE CURRENT WORKING.*

BY W. M. MORDEY.

(Concluded from page 460.)

The paper of Profs. Ayrton and Perry, read last year before the Physical Society,† showed that the efficiency of glow lamps is the same for both direct and alternating currents. The authors of that paper did not directly allude to the question of relative efficiency with different periodicities, but they evidently had this point in their minds, as the periodicities used in the experiments appear to have been varied from 83 to 226 without showing any difference in efficiency. It may be taken, therefore, that no difference exists. Probably for very low periodicities this would not hold good, but for ordinary rates the question may be considered settled. At very low rates the temperature of the filament would follow to some extent the changes of the current, and would be affected both in life and in efficiency. I suppose that at ordinary rates there is no variation of temperature, the filament acting as a kind of thermal flywheel, maintaining its condition unchanged throughout the whole period. We all know, for instance, that especially with low-resistance lamps, when the current is interrupted the time occupied in cooling down to blackness is quite appreciable. The periodicity at which the temperature begins to follow the variations of current is a point of some interest, and it is one that can be very easily investigated.

There is, as far as I am aware, no available evidence regarding the life of lamps with different rates, or even as to the relative life with direct and alternate currents. At one time it was considered that alternate currents would give better results than direct currents, because with the latter there was supposed to be some transference of the material of the filament in the direction of the current. Nothing has transpired to confirm or to disprove this supposition, and, as the number of lamps now in use on each system is enormous, the very absence of evidence may be taken as affording a strong presumption in favour of the belief that the life of lamps is independent of whether the current is direct or alternating, and independent also of the periodicity, within practical limits.

Alternate-current arc lamps are not seriously affected by variations of periodicity within a fairly wide range. The feeding current of a parallel Brush alternate-current lamp remains sensibly constant between 75 and 125 periods, but with the lower rate a slightly higher impedance or resistance is required to secure steadiness of the light.

Secondary E.M.F. of Transformers.

The best potential difference to be used on transformer circuits has been a good deal discussed, especially with reference to the voltage of lamps. It is very desirable to arrive at some conclusions on this matter, not only as to glow lamps, but as to the general question.

The balance of opinion—which is, however, not very decisive—appears to be in favour of using 50-volt rather than 100-volt lamps, so far as durability of the lamp is concerned. The stout low-tension filament should last longer than the finer one for high tension, because disintegration does not so soon reduce the cross section to the breaking point. It is, however, not a question only of life, as the disintegration of the thick filament causes blackening of the globe; and if it can be shown that this blackening, and the consequent lowering of the effective light, is more serious than in 100-volt lamps, then the advantage of slightly longer life will not of itself be sufficient to recommend 50-volt lamps in preference to others of higher voltage.

Of course, the most serious objection to lowering the voltage is the increased cost of the secondary conductors. This is not important in small and very compact installations such as can be so readily supplied by transformers—for instance, in small shops and ordinary houses, where a separate transformer may be placed within a few yards of the lamps, and where the fall of potential is negligible; but for larger work it is advisable to keep the potential difference high, as with direct currents, and for the additional reason that the use of very large alternate currents, with correspondingly large conductors, is accompanied by the inconveniences arising from the high virtual resistance already alluded to.

It is impossible, however, to choose an E.M.F. that will meet all requirements. For instance, high candle-power lamps are coming largely into use, and as this practice extends, higher E.M.F. will be demanded in order to keep down the diameter of the "stick."

But, on the other hand, lamps of small candle-power can be more easily made for low than for high voltage; and as there is a growing tendency to use small candle-power lamps which in many situations give all the light that is required, this point should be kept in mind, especially as it is very probable that before long a demand will spring up for lamps of three or four candles. I know it will be said that it is easy to reduce the candle-power of ordinary lamps by inserting an impedance coil in the circuit. This is one of the many conveniences of transformer working, but it should not be resorted to for permanent purposes, as, however little power such a coil may absorb, lamps reduced in that way, being worked at less than their normal candle-power, are very inefficient.

Then there is another reason for sometimes preferring 50 volts to 100 volts that I should like to mention, and that is that alternate-current arc lamps do not require more than 50 volts terminal pressure. It may be expected that many such lamps will be used on transformers—for instance, at small business places, where perhaps the bulk of the lighting will be internal and by incandescence lamps, but where it will be convenient to have one or two arcs outside. We know that when arcs are used in parallel with incandescence lamps on direct-current circuits, it is necessary, in order to get the best results, to have 12 to 15 volts drop of pressure in a fixed resistance in series with each arc. Thus has arisen the custom of using 65 volts for mixed arc and glow lamp circuits, where the potential difference at the arc lamp terminals is reduced to about 50 volts by the insertion of such a resistance, the incandescence lamps, however, being made to work at 65 volts.

This is a very wasteful arrangement, but, apart from its wastefulness, 65 volts is a very inconvenient pressure both from the manufacturer's and the consumer's point of view. It does not lend itself to combination as does a pressure of 50 volts dynamos, lamps, or transformers, for 65 volts cannot be used in pairs on 100-volt circuits as can such apparatus for 50 volts. It is an irregular and inconvenient pressure that is demanded by the necessities of direct currents, but that I am glad to be able to say need not be imported into alternate-current work.

This very serious loss can be almost entirely avoided with alternate-current arcs, as the necessary steadying effect is readily obtained by the use of an impedance coil, absorbing much less power than does a resistance; and as such arcs require only 35 to 40 volts between the carbons, instead of 45 to 50 with direct currents, it is sufficient to provide 50 volts potential difference between the secondary conductor.

But it may be said that, as impedance coils absorb little power, the arc lamps may be put on 100-volt circuits in parallel. This may be done without much objection so far as the lamp and impedance coil are concerned, but there is the drawback that the "plant-efficiency" of the transformer will then be low.

The output of a transformer is limited partly by the size of the conductor. The actual output of a 100-volt transformer supplying arcs through impedance coils will not be much more than the product of the current × 50 volts, while for the same output in watts on glow lamps it would only have to yield about half the current. Therefore we see that, although not inefficient, the maximum allowable output of a 100-volt transformer on parallel arc lamps is only about one-half of its ordinary maximum output.

It will be said that two arcs may be run in series on the 100-volt secondary. This is true, but two arcs are not always wanted; and, further, the working of two arcs (which must for this purpose be shunt or differential, instead of simply series-wound) in series on a constant potential difference is the least satisfactory way of arranging arcs, whether for direct or alternate current, as in this way they affect one another the most, having neither the margin of controlling power by current, which is provided in the parallel constant potential difference arrangement, nor by E.M.F., as in the series constant-current arrangement. Then, again, lamps so connected must be extinguished together, as no cut-out or switch can be used unless it is made to insert a resistance or impedance to take the place of the extinguished lamp.

On the whole, therefore, it is preferable to have 50-volt secondaries where arcs are to be used, or to adopt the intermediate plan of connecting the middle of the 100-volt secondary to a third terminal, using a third wire for any arcs or 50-volt lamps that may be required. It may be worth while to point out that the use of a third wire on transformer circuits may lead to difficulty if not carefully considered. With a single transformer it is as easy to use three or any other number of terminals for the lamps as it is to do so on a set of accumulators, and to get any corresponding potential difference. The various sections of the secondary may be unequally loaded by this arrangement, but the primary responds as a whole to the demand made upon it. If, however, instead of a single transformer, two transformers are used, with their primaries and secondaries respectively in series, then the use of the three-wire principle is only possible when it is applied to both the primary and secondary circuits, unless the load on each of the two secondaries is always to be alike and the same, in which case, as scarcely need be said, there is no particular advantage in using three wires. If the loads are not equal on the two, then the primary of the least loaded transformer acts as an impedance coil to the other primary, and all power of self-regulation is lost. One remedy for this is to apply the three-wire principle to the primary as well as to the secondary; but this is a serious matter, and one that could only be undertaken where the whole service demanded it. Another plan is to have two mains for the primary and three for the secondary, and to join the primaries parallel, the secondaries being in series with the third wire at the middle terminal.

In cases where arcs have not to be used, and in the absence of any very strong evidence of any difference of life in favour of 50-volt lamps, I think it is best to use 50 volts for small separate installations, and 100 volts for larger ones; but it is evident from what has been said that there are so many points to consider that it is quite impossible to give any definite negative or affirmative reply to the question, "What is the best secondary E.M.F. to use?" Each case, or at least each class of cases, must be settled on its merits. If for general convenience any particular pressure is selected, it is obvious that it will have about equally strong arguments for and against it.

Alternate-Current Arcs.

Reverting to this subject, it is to be regretted that very little appears to be commonly known about A.C. arcs. I trust that in the discussion of this paper some information may be furnished with regard to them.

As to the regulating mechanism of lamps, although some difficulties were encountered in modifying the Brush arc lamp for this work, the result has been perfectly satisfactory. The feeding range is very small—quite as small as with direct currents, and with no greater loss of power in the lampbox. Some trouble was experienced in getting rid of noise and vibration in the coils and mechanism, but this has been completely overcome, the lamp itself being quite silent. This is readily proved by connecting the carbon-holders by a flexible wire and adjusting the current to the normal value, when it is found that

* Paper read before the Institution of Electrical Engineers.

† *Jour.* Phys. Soc., vol. ix., p. 208.

Digitized by Google

there is no noise. An A.C. arc is not silent, as is well known, a distinct hum being set up, by which it is quite possible to ascertain the periodicity.

This humming noise, which can scarcely be expected to be overcome, renders A.C. arcs unsuited for general use indoors; but for outside illumination, and for such places as railway stations, they will certainly find a very extensive application.

I venture to think that the opinion so often expressed, that A.C. arcs give much less light than those supplied with direct current, is founded on a misunderstanding of the proper conditions. It is quite true that if two arcs are compared, supplied with the same amount of current, the direct-current lamp will prove the better one. This, I think, is because the basis of comparison is not right. In many cases the A.C. arcs are more efficient. They should be judged by the energy, and not only by the current. I have mentioned that an A.C. arc requires only 35 to 40 volts potential difference between the carbons, while a direct-current arc requires 45 to 50 volts. The mean may be taken at 37·5 and 47·5 volts respectively, and to expend the same energy in the two cases the current should therefore be in the inverse ratio of these values. Thus an A.C. arc, to give the same light, and to absorb the same power as a 10-ampere direct-current arc, should be made for 12·6 amperes.

In one respect A.C. arcs are inferior, and that is in their power of directing the light downwards. They have no "crater," and, therefore, do not send the light down as do direct-current arcs. On this account it is advisable to use reflectors above them, unless they are suspended below and near a good reflecting ceiling or roof.

But even this drawback is counteracted in parallel work by their greater efficiency. On a 65-volt circuit with direct currents, as I mention elsewhere, there is a waste of 100 to 150 watts with a 10-ampere arc, and in the same proportion with other currents. This is a very serious proportion of the whole power, and it is only allowable to waste it because, as a light-producer, the arc is so much more efficient than the incandescence lamp. Nevertheless, any means of avoiding the loss is to be welcomed, and with A.C. arcs it may be greatly reduced by the use of impedance coils, which, if properly designed, waste very little power, and have all the steadying effect of resistances.

Safety and Safeguards.

I take this opportunity of bringing up this question, not because I have anything new to say with regard to it, but in order, if possible, to bring it a little nearer to a rational settlement.

It will be acknowledged that the first duty of an "undertaker" using high tension is to provide for the complete and absolute safety of the consumers. If there are no means of doing this, then the system is fundamentally bad, and must sooner or later be abandoned.

There are several ways of protecting the house mains more or less completely. I only need allude to three typical plans, all of which have already been discussed before this Institution.

One is the plan introduced by Mr. Kent, of entirely separating the primary and secondary conductors in a transformer by a sheet or division of earth-connected metal. This is open to adverse criticism on some points, but on the whole it is an effective plan.

Another arrangement is the ingenious one of Capt. Cardew, consisting of a sort of static mousetrap, which immediately goes off when an unauthorised P.D. enters it.

The third plan is that of earthing the secondary, and it would be very instructive if those who so strongly oppose this plan would state just one real objection to it. It is a perfectly sure method, and costs nothing.

It renders it absolutely impossible for the consumer to get a dangerous shock under any possible combination of circumstances whatever.

The faults that may occur are (*a*) Contact between primary main or mains and earth. (*b*) Contact between primary and secondary in a transformer. (*c*) Contact between a person and a portion of the secondary conductor. (*d*) Contact between that person and earth.

Now, if all these contacts occur at the same time, the "person" will get a shock.

But if the secondary is earthed, no shock can be obtained, except, perhaps, a slight one, due to the secondary P.D.

This simple plan has been approved by almost everybody, but it is received with opposition on the part of some of the fire insurance offices and others.

It is difficult to ascertain where the supposed danger is. If the secondary is earthed, the effect of a contact between primary and secondary, when the former is accidentally leaky, is at once to blow out the primary safety fuse of the transformer, and so cut out the offending house. This is the simplest and the best course to take, and prevents the continuance on the circuit of transformers that contain faults.

The Brush Corporation has adopted this plan with perfect success on a large installation abroad, and intends adhering to it where local circumstances permit.

It is to be remarked that it is not open to the objection that has been stated against earthing of one of the primary conductors—viz., that the telephones may be affected—for it is not permanent. The moment a contact occurs that could lead to a disturbance of the telephones, the fuse prevents that disturbance being continued.

While effectually removing life risks, this precaution does not increase fire risks; in fact, it tends to greater safety, as it is some sort of check on the character of the house wiring work, and so reduces chances of faults, such as short-circuiting of the secondary.

The rupture of a primary safety fuse is not a serious matter, and in any case it is only what takes place under ordinary circumstances when any fault occurs that results in an excess of current.

As to static effects, I think it will be found that there will always be enough general leakage to prevent such effects being a cause of difficulty, even if the secondary circuits are not earthed.

Hysteresis and Eddy Currents.

Some explanation is necessary by way of preface to this section of the paper. The experiments described were made with a direct-current dynamo, and on that account they only touch the fringe of this division of the subject. As I had no suitable alternator, I was unable to pursue the question as far as I wished to do, but I hope I need make no apology for bringing forward such results as I have been able to arrive at.

As far as I am aware, no simple or practical method is known by which the power absorbed in eddy currents can be determined and separated from that due to hysteresis in the armatures of dynamos. This is a point of some importance, both as regards alternators and direct-current machines, for many reasons, one of the principal being that in the absence of exact knowledge on these matters it is difficult or impossible to determine to what extent the lamination of the iron cores should be carried. There are wide differences in the practice of the various designers and makers of dynamos in the thickness of the iron used.

Lamination may be carried to such a degree of fineness for the purpose of reducing eddy currents as to add very materially to the cost of production, the iron increasing rapidly in price as the thickness is reduced; and it may be that the point is sometimes passed beyond which no gain in efficiency is obtained. This is a question we wish to be enabled to settle.

Until Prof. Ewing* and Dr. J. Hopkinson† read their Royal Society papers on the subject, very little was known of the heating effect of changes of magnetism. Prof. Ewing opens the part of his paper dealing with this matter in the following terms (p. 552, *Phil. Trans.*): "The energy expended in a cyclic process of magnetisation can take no other form than that of heat diffused throughout the substance of the metal. Experiments have been made by Joule and others to determine by direct observation the heating effect of magnetisation in iron.‡

"In most direct measurements of this quantity no distinction is made between the heating effect due to the induction of electric currents and that due to changes of magnetisation *per se*; and so excellent an authority as Prof. Rowland, writing in 1881, has expressed himself as doubtful whether changes of magnetisation, considered apart from the currents they induce, give rise to any development of heat at all."

Further on, Prof. Ewing, referring to the dissipation of energy by hysteresis, which he had determined by laboratory experiments, says, (*Phil. Trans.*, pp. 553, 554): "These developments of heat are so small as to make it apparent that the very considerable thermal effects which reversals of magnetism cause in the revolving cores of some dynamo-electric machines must be due almost wholly to the internal induction of currents, so far as they are not due directly to the current circulating in the coils of the armature.

"The experiments have a practical value in showing that cores which are so thoroughly laminated as to render the induction of currents within them unimportant, do not involve any serious loss of energy; and that the efficiency of a machine with a soft iron core or cores whose magnetism is periodically reversed need not, on that account, be materially less than that of a machine which has no such cores. The absence of iron from the armature has been claimed, on the score of efficiency, as an important advantage possessed by some types of machine, but unless the claim has some other basis it appears to me to be illusory. Magnetic reversal does involve some loss of energy, but if the cores are properly laminated it is so small as to be practically insignificant."

I quote these passages as showing the position of the question. Prof. Ewing and Dr. Hopkinson give laboratory determinations of the magnetic loss in iron with various inductions and under various conditions. It is, however, left somewhat in doubt as to whether the loss in dynamo armatures will be the same as in the laboratory experiments, the conditions being very different in the two cases.

On this point Prof. Ewing shows that hysteresis is much less when the iron is in a state of mechanical vibration than when it is in a state of rest, and states that in a dynamo the loss will be less than the experiments on still metal might lead us to expect.

Another way in which the dynamo conditions may cause some difference is the possible variations of the magnetic density that may exist in the core. Such variation may be considerable in armatures of large size.

Dr. Hopkinson (*Phil. Trans.*, p. 467) takes the magnetic loss in armatures as being the same as in the small pieces of iron tested by his method, and gives an example calculated for an armature-core "finely divided, to avoid local electric currents."

It is to be noted, then, that both these authorities regarded eddy currents as unimportant in laminated armatures; but in the later paper on "Dynamo-Electric Machinery,"§ Drs. J. and E. Hopkinson published their famous investigation into the efficiency of dynamos, and gave very full particulars, from a study of which it is possible to ascertain the loss in eddies, on the assumption that the method of calculating the magnetic loss is correct when applied to armatures—a point which Dr. Hopkinson was not able to decide positively; but by assuming that it is applicable, then, by subtracting the calculated hysteresis loss from the ascertained total power unaccounted for, the eddy-current loss is obtained; and as this process gives the hysteresis as accounting for only about 40 per cent. of the total loss in the arma-

ture core, it shows that the eddies could not by any means be considered unimportant, although the lamination was carried out to the extent of making the iron about 0·02in. thick.

I now wish to describe a method by which the amount of loss due to each of the two causes may be ascertained experimentally in the workshop on a practical scale. It is a very simple one, although not, perhaps, capable in all cases of the highest scientific accuracy.

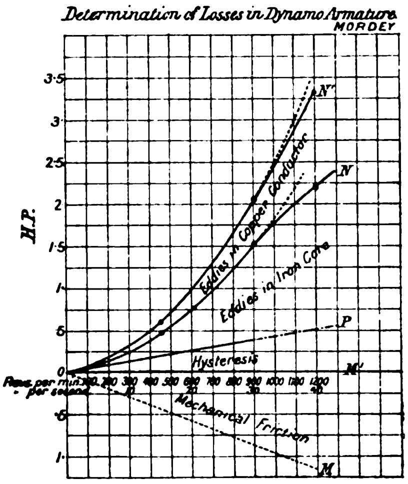

FIG. 3.

(*a.*) First run the dynamo on open circuit at various speeds (two readings will suffice), with the fields unexcited, or, better still, entirely absent, and measure the power absorbed in friction. Plot this value to any suitable scale, as O M in Fig. 3, the ordinates representing horse-power, while the abscissæ represent revolutions per minute.

In the figure the mechanical friction, being a quantity with which in this investigation we are not directly concerned, is plotted below the base line O M', in order that the other losses may be more clearly seen.

(*b.*) Next, run again on open armature circuit with the brushes removed, and the field normally excited, and measure the power absorbed. This will be the total power dissipated in friction, hysteresis, and eddy currents, if any, and must be plotted as O N. Then the ordinates lying between O N and O M' represent the sum of the losses due to hysteresis and eddy currents, and somewhere between O M' and O N must lie a line O P, separating the hysteresis from the eddy currents.

We desire to find the position of this line. The difference between the rate of increase of the electric and magnetic losses enables us to separate them from each other. It may be taken that with any given constant excitation the loss from hysteresis is directly proportional to speed, within certain limits to be hereafter stated. The resistance (that of the iron) being constant, the eddy currents must vary as the first power of the speed, and the loss therefrom as the square of the speed.*

It will now be seen that it is easy to separate the values which are directly proportional from those which are proportional to the square of the speed.

Prof. S. P. Thompson, to whom I submitted this method, has kindly given me the following concise formulæ for finding the quantities :—

P and P_1 are respectively the combined magnetic and electric losses at the speeds S and S_1.

k = magnetic loss ;

k_1 = electric loss.

$$k = \frac{P_1 S^2 - P S_1^2}{S^2 S_1 - S S_1^2};$$

$$k_1 = \frac{P S_1 - P_1 S}{S^2 S_1 - S S_1^2}.$$

Then, at any speed n,

Hysteresis $= k\,n$;

Eddies $= k_1\,n^2$.

If armature cores are run in an excited field before winding, it can be determined to what extent their lamination is satisfactory, and whether the iron is of good quality ; and then, after winding the armature-conductors, another test shows what the additional increase in the loss is, and separates the effects of eddy currents in the core from those in the conductor, and the hysteresis from both. The method may also be useful to investigate the losses in the cores of armatures of different types, or differently built up, as for instance, with iron wire or iron sheets.

This method has a useful application in rendering it possible to separate not only the magnetic loss from the electric loss in the iron, but to determine the waste by eddies in the copper winding of armatures.

It is usually entirely a matter of opinion as to how much of the power absorbed in running an armature on open circuit is due to any of the various causes referred to ; and now that it is customary to wind armatures with heavy conductors, it becomes very desirable to be able to find in any particular case what proportion of the loss is in the copper, and what in the iron.

* Prof. Thompson's ' Dynamo-Electric Machinery." Third edition, p. 102.

In Fig. 3 are shown some results obtained with a four-pole (direct-current) Victoria dynamo run at various speeds up to 1,200 revolutions per minute, with constant excitation. Power readings were taken by means of a White's transmission dynamometer, constructed by the Brush Corporation for the purpose of testing dynamos ; and the horse-power absorbed in mechanical friction in dynamo, belt, and dynamometer was subtracted from the power spent electrically and magnetically.

To reduce errors in the dynamometer readings the dynamo was fitted with two pulleys, one twice the diameter of the other. This allowed of the dynamometer being run at the same speed, while two different speeds of the dynamo were obtained by changing the belt from one pulley to the other. Readings were taken at four speeds—viz., 450, 600, 900, and 1,200 revolutions per minute, corresponding to 15, 20, 30, and 40 periods per second. The position of O P was readily found by "trial and error," this being a shorter process for a concrete instance than the application of the general formulæ. The assumption on which this method of testing is based was found to be correct up to 900 revolutions. The reading at the higher speed of 1,200 revolutions, or 40 periods, shows that disturbing influences began to affect the results by reducing the rate of increase of the losses. The continuation of the curve, O N, in a full line shows the actual loss, while the continuation in a dotted line, which is a parabola on O P as an abscissa, shows what the loss would be if the rate of increase holding for low speeds were maintained.

This shows that this method is perfectly applicable to ordinary direct-current machines—for instance, to two-pole dynamos up to 1,800 revolutions per minute, or 30 periods per second—but that it is less useful for alternators.

The disturbing causes are probably rather complicated. They may be due partly to self-induction in the circuits of the eddy currents, to lower magnetisation (although this effect, if present, is very slight, as was shown by the E.M.F. being almost perfectly proportional to speed), and to vibration. "Viscous hysteresis," if it exists, will raise the magnetic loss. There may be such an effect in spite of the lowering of the curve, but it cannot be recognised, on account of the unknown variations of the eddies, at the higher speed. Iron-cored alternators working at high periodicities may be tested in the following way, which will give some approach to correct results : Let the test be taken at a low speed (not more than 30 periods). This will give the hysteresis per period, and the eddies at that speed. Then, if at any higher speed the E.M.F. is proportional to speed, it may be assumed that the magnetic induction is the same as before, and the hysteresis per period will at any rate not be less than at the lower speed. It may be more. The difference between the calculated hysteresis, O P, and the ascertained total loss, O N, will be the eddies ; or, if viscous hysteresis is a fact, it will be extra loss due to viscosity plus that due to eddies.

Heating of the armature-core, and consequent increase of the resistance of the iron, is not responsible for the bending down of the curve O N in Fig. 3 (although it would have that effect under ordinary circumstances), as the experiments did not occupy sufficient time to allow of any sensible rise of temperature. The effect is probably very complex and obscure, but it is one that well deserves study, on account of its present industrial importance.

It should be stated that the dissipation of energy (which has been spoken of as being in the armature) may be partly in the field-magnets. This was, however, not the case in the experiments referred to The conditions necessary for the prevention or reduction of eddies in the iron of field-magnets are now pretty generally understood ;* but it should be observed that it is not by any means as easy to check such waste in alternators as in ordinary dynamos. It is both better and easier to prevent than to cure them.

If a good transmission dynamometer is not available, results almost, or perhaps quite, as good may be obtained by running the machine at various speeds by means of an electric motor, and measuring the power required by the motor—first with the fields of the machine unexcited, to get the mechanical friction, and then with the fields excited, to get the total loss. The motor should then be run alone, to find what is absorbed in driving it at various speeds. The increase in watts over these last values, with the internal losses in the motor-conductors calculated out and subtracted, will give, with a very fair degree of accuracy, the energy dissipated in the machine under test.

The upper curve, O N', was plotted from readings taken after the armature was wound, and the difference in the ordinates between O N and O N' shows the eddy-current loss in the copper conductor at various speeds. This loss, like that of the eddy currents in the iron, rises as the square of the speed up to 900 revolutions, or 30 periods, above which it rises rather less quickly. The full line, O N, shows the actual loss, the dotted line above it showing what it would be if the rate of increase were maintained. The difference is no doubt due to self-induction.

That the effect of self-induction is not noticeable unless the eddy currents are considerable is in accordance with experiments that I published some years ago in connection with the Brush dynamo. The results then obtained are shown in Fig. 4. The straight line connects speed and the potential difference at the terminals with the laminated armature ; the lower and slightly curved line shows the potential difference with the old form of cast-iron armature, which had only coarse divisions, scarcely meriting the term "lamination." The curve shows that the E.M.F. rose less quickly than the speed on account of the serious generation of eddy currents.

In the laminated armature, although, of course, there were still eddies, their effect was not sufficient to cause any bending down of the E.M.F. line at any practicable speed of driving.

Coming now to an examination of the results obtained in the

* See numerous practical notes on this subject scattered through Prof. Thompson's "Dynamo-Electric Machinery."

Digitized by Google

experiments, and shown in Fig. 3, we see that the hysteresis loss in this particular dynamo—which I should mention is capable of working continuously with a normal load of 18,000 watts—was 0·195 h.p. at 450 revolutions, and 0·39 h.p. at 900 revolutions, the latter corresponding to 30 periods per second.

The magnetisation* was about 12,300 C.G.S. lines—not by any means a high density. The armature had a ring core, nearly square in cross-section, of 12 square inches area, and contained 615 cubic inches, or 10,096 cubic centimetres of iron strip 0·012in. thick (No. 30 B.W.G.) separated by paper. This is a degree of lamination beyond which it is inconvenient to go. The pheripheral portion was wound with this iron in parallel bands ½in. wide, in order to reduce eddies caused by lines entering the periphery. The main inner portion of the core was of wider strip.

We find from the figures that the loss in hysteresis at 900 revolutions was as follows:

0·39 h.p. = 291 watts = 0·473 watts per cubic inch, or 0·029 watts per cubic centimetre. As the periodicity was 30, the dissipation of energy per complete period per cubic centimetre was 9,613 ergs or 0·001 watts, nearly.

It is interesting to compare this result, obtained in what may seem a rather crude manner, with the values given in the papers referred to. Prof. Ewing says (*Phil. Trans.*, p. 553) ". . . the double reversal of a strong condition of magnetism in soft iron involves the expenditure of about 10,000 ergs per cubic centim." He gives the energy as 9,300 ergs, with a magnetisation of 13,190 in very soft annealed iron. Dr. Hopkinson gives 13,356 ergs, with a magnetisation of 18,250.

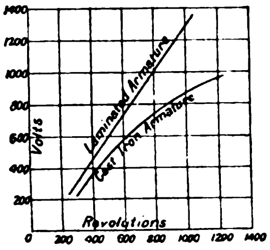

FIG. 4.

a a, Armature Coils; *b b*, Field Poles.

FIG. 5.

Much of course, depends upon the quality and hardness of the iron, but my results come out very close to those of Prof. Ewing and Dr. Hopkinson. This may be taken as proving the method capable of considerable accuracy. The eddies in the iron, it will be seen, are by no means to be neglected, even with the very fine subdivision that was used.

The eddies in the conductor are rather greater than usual, as the armature, being intended for a very low speed, had a larger amount of copper on it than usual.

The bearing of these curves on iron-cored alternators, and on open circuit working generally is obvious. With a magnetisation of 12,000, the loss in hysteresis alone, at 100 periods, would be over 1·5 watts per cubic inch of iron core, and the eddies would amount to a good deal more. I will only add that the eddies, both in the iron and in the copper, are greatest when no external work is being done, as was the case in my experiments. They are reduced by the effects of self-induction when the circuit is closed. A difference exists in this respect between generators and motors, a difference in favour of generators.†

I will not further extend this paper by dealing at greater length with this part of the subject.

APPENDIX.

Extract from remarks by Mr. Mordey in the discussion on Mr. Kapp's paper on "Alternate Current Machinery."—*Proc.* Inst. C.E., March 5, 1889.

"Alternators might be divided into two classes—those which had iron in the armatures, and those which had not. As his own machine, made by the Brush Corporation, and that of Ferranti were the only examples of the latter class described by the author, he might be permitted to mention the reasons which had led him to avoid the use of iron. He thought the makers of dynamos would agree that almost all the ills that the dynamo was heir to were due to the presence of the iron in the armature. Its use in direct-current machines might be said to be a necessary evil, as, although attempts had been made to do without it, all successful types of such machines required it for structural purposes. Iron in armatures, when worked at a high magnetic density, and with rapid reversals or variations of magnetisms, became heated, and wasted a good deal of power. In alternators, this objection applied with very much greater force than in direct-current machines, for in the latter the reversals of magnetism were comparatively slow. Thus the first result arrived at in quite recent practice is that the magnetic density that can be used in iron-cored alternators must only be about one-half that employed in continuous-current armatures. This alone meant a considerable increase in the size of armatures, without any gain in output or efficiency. Although the loss per cubic inch was reduced by decreasing the magnetic density, the armature had to be made larger to compensate for it, and the total loss was actually increased, not reduced. Iron was used to reduce the magnetic resistance, to afford mechanical support, and to introduce self-induction into the circuit. The latter, an evil in itself was said to be a modern necessity, caused by the convenience of working alternators parallel. Self-induction, for this or any other purpose, had probably not entered the minds of most designers at the time they first produced their machines, except, perhaps, as an objectionable feature, which they could not get rid of; but now it was being brought forward as an advantage. If iron was indispensable for this purpose, which he was not prepared to admit, it could readily be inserted in some part of the circuit where ample space and cooling surface could be provided, and from which it could be easily removed when not required, that was when it was only necessary to run one machine. The armature was the very worst place to put the iron, for there its presence was the most objectionable, and it was there least under control. Referring to the magnetic resistance of armatures, it would be seen that there were broadly two ways of arranging the armature-coils and the field poles. The poles could be arranged north and south, facing one another, the armature-coils having their axes parallel to the lines of force; or the poles could be arranged in successive order round an iron ring or drum armature-core, on which the armature-coils were wound or placed. If iron cores were used in the former case, the output would be only about one-half of what was obtained with air cores, on account of the necessity to work with reduced magnetic density, while at the same time magnetic and electric disturbances would be set up, both in the armature and field, wasting power, causing objectionable heating, necessitating lamination of the fields, and demanding an increase in the exciting power. These reasons were sufficient to explain why he had not used iron cores; but there were others. Magnetic resistance, between pole and pole, was made up partly of the necessary clearance space, partly in most cases of the space occupied by the copper conductors, and partly of the iron or other core. Now, if in air-cored armatures the core could be so arranged, as was quite possible, and was done in his own machine, that it occupied no more space than was taken by twice the depth of the conductors in iron-cored armatures, it would be evident that the former gained instead of lost by the omission of iron. They gained not only in magnetic resistance, but in all the other points to which he had referred, and they had the very great advantage that there was nothing to limit the magnetic density at which they could be worked except the magnetic saturation of the field-poles, the only losses to be met and provided for being the ordinary electrical losses in the conductor caused by the passage of the current, and a small waste by eddy currents in the conductors and supports. Such armatures had the further advantage that their self-induction was negligible, their power of self-regulation was very great, and that on open circuit or light load they ran very economically; whereas it was well known that, when iron cores were used, the losses under such circumstances were often very serious indeed. He thought it was quite unnecessary to use iron cores for the purpose of obtaining mechanical support for the armature-winding. The holding and driving, with a very limited clearance, of an armature consisting of thin iron, separated by such unmechanical substances as paper, and overwound with copper wire, itself covered with cotton, and expanding and throwing out from the combined effects of heating and centrifugal action, was a problem that had never been very successfully solved in direct-current machines, and was certainly to be avoided, if possible, under the still more onerous conditions obtaining in alternators, where the electrical pressure was usually much higher than in direct-current machines, and in which, as the author showed, the maximum mechanical strain on the wires was greater. He ventured to think it was much the best to make the armature stationary as he had done. It then had only to resist the tangential drag of the field. He thought a great mistake was made in some alternators in using Pacinotti projections. In all cases there should be, as nearly as possible, a steady magnetic flux in the field. This could not be done if projections were used. The Zipernowski and Parsons machines were faulty in this respect. It was impossible to tell, by inspection of the former, which was the armature and which the field. They seemed quite interchangeable, and this was, of course, not right. In these two machines, it would be seen that the magnetic resistance varied very much, as the iron projections passed through the cycle. This necessarily led to losses in the field, the lamination of which recently introduced in the Zipernowski machine showing that such losses must be serious. There was one other machine to which he wished to allude, and that was to him a very interesting machine indeed. He referred to the alternator shown and referred to by Prof. Forbes as in some respects a development of his alternator. In that machine Prof. Forbes used the form of field which he (Mr. Mordey) had in his alternator; but he used it in combination with a form of armature having, like the field, only one coil. He ventured to point out that, for a machine with an iron armature, that form of alternator had some advantages. The armature might be described as a Gramme ring, with the copper inside and the iron outside. The magnetic flux was, or might, be made perfectly even, the air-gap was very short, the magnetic resistance very low, and it followed that the excitation required was very small. The author had alluded to a very interesting and important matter, probably new to most people, as it certainly was to him, namely, that the armature-conductors in alternators showed a tendency to heat much more than in the continuous-current machines, but in this machine described by Prof. Forbes there was hardly any question of eddy currents in the armature-conductor, as the coil was not swept by the lines of force. Further, it was evident that a very low current density could be used in the armature-coil without sensibly affecting the size, cost, or output, and it was also clear that the insulation of the armature-coil was a very simple matter. Another good point was that neither the armature-coil nor the field coil need be rotated. For a machine with an iron magnetic circuit he thought this was a very good one; and he had only one other remark to make about it, and that was that he had himself invented and patented it some time ago!

* The use of the word "induction" in so many senses is apt to cause confusion. "Magnetisation" would, perhaps, be better than "induction," "magnetic induction," "density," "magnetic density," etc.

† *Phil. Mag.*, January, 1886, p. 26. "The Dynamo as a Generator and as a Motor."

Digitized by Google

It was, he thought, a natural development of his alternator. He was glad to find that Prof. Forbes had had the same idea, because that showed it to be a good one. Much had been said about the form of the wave yielded by alternators. He had some time ago made an experiment with the first of his machines, using the method described by Prof. Ayrton, and found that the curve was almost a sine curve. On the subject of the lag in transformers, to which Prof. Ayrton had also alluded, he might be allowed to mention that, in the discussion of another paper by the author, he had first stated the fact,* and had described a very simple experiment, showing that the primary and secondary currents reached their maxima and minima practically at the same time."

DISCUSSION.

Before the discussion was proceeded with, the author exhibited and described an automatic current regulator arranged to work within ½ per cent. without "hunting," and also explained a model and drawings of his "single coil alternator." During the week he had received letters, amongst others, from Lord Rayleigh, Prof. Ewing, and Mr. Zipernowski, bearing on his paper, from which he now read extracts. Lord Rayleigh pointed out in the *Phil. Mag.* for 1886 he had worked out the virtual resistance of conductors. He also thought the term "frequency" better than "periodicity." Prof. Ewing referred to the work lost in hysteresis, and Mr. Zipernowski promised to forward his criticisms later on.

Prof. Forbes read some notes by **Dr. Hopkinson**, who states that to obtain direct control in parallel working, neither large self-induction nor small self-induction are essential, but the best control is exerted when $\frac{2\pi\gamma}{T}=r+R$, where γ=coefficient of self-induction, T=per period, and r=R is the resistance of armature and leads. If the resistance of the leads or feeders be considerable, parallel working is more difficult. In his paper of November 13, 1884, the case of putting generators giving different E.M.F.'s in parallel was shown to be feasible, and from the equations of § 3 the work done by the leading machine becomes zero when $\frac{2\pi\tau}{T}=\frac{\pi}{2}$ where 2τ is the difference in time phase. Dr. Hopkinson also says that all the phenomena observed by Mr. Mordey could be predicted from his 1884 theory.

In a communication from **Prof. Adams**, read by Prof. S. P. Thompson, attention is directed to the South Foreland trials of 1884, and described in his paper read on Nov. 13 of that year, in which many of the experiments mentioned in Mr. Mordey's paper were performed satisfactorily. He regarded Mr. Mordey's statement on page 4, that alternators with small self-induction and resistance will best run parallel "because they will be the best synchronising motors," as equivalent to "saying that tuning-forks synchronise when in unison." Reference was made to the beats by the synchronising lamp when one machine was running at half the speed of the other, and from acoustical analogues Prof. Adams thinks alternators will run as motors at speeds corresponding to fractions or multiples of that of the generator. He attributes the active cause of synchronising to self-induction, and considers that the groaning heard when the machines were switched parallel to confirm this view.

Major Cardew, referring to the frequency at which the temperature of lamp filaments begin to follow the current, said that in experiments on signal-flashes about ten changes per second could be clearly seen. The section on safety and safeguards seems to him to imply that the faults (*a*), (*b*), (*c*), (*d*), must occur simultaneously if a person is to receive a shock, but the speaker thought (*a*) and (*b*) may exist unknown to a person who accidentally, or otherwise, touches the secondary whilst making contact with earth. Earthing the secondary, though safe as regards shocks, might considerably increase fire risks.

Dr. Fleming, speaking from information recently obtained in Milan, said there was no difference between the average life of lamps worked by direct or alternating currents. As a possible explanation of the observations on the periodicity which gives maximum efficiency, he suggested that for rapid changes the viscous hysteresis was most important, whilst for slow ones the eddy currents penetrated further into the metal, thereby wasting more energy. He thought the Institution was greatly indebted to Mr. Mordey for demonstrating successful parallel working without much self-induction or resistance, and pointed out that to work alternators parallel satisfactorily, not only must the machines come into step, but they must do so promptly, and considerable stability must exist. These conditions may be satisfied by suitably shaping the field-poles and armature-coils, for on these the shape of the E.M.F. curve depends.

Mr. Kapp complimented the author on his valuable paper, not as a formality, but because it was one of the best ever brought before the Society. In his remarks on the paper he thought it was not at all clear how the E.M.F. of a machine excited to give 1,000 volts rises to 1,500 when placed in parallel with one giving 2,000 volts, but, according to his idea, was probably due to the armature current demagnetising the fields of the generator and magnetising those of the motor. He questioned whether the self-induction of the armature was insignificant, for when the field-poles were central with the coils they would act as cores for the coils, which would therefore have considerable self-induction. This will vary with the relative positions of the magnet and armature, and tend to pull the machines into step.

Mr. Swinburne suggested, as a satisfactory test of parallel working, that the machines should be capable of being kept on full load without undue heating of the armatures. Referring to the word "synchronising," he thought its use in the paper rather ambiguous, for in some cases it related to "speed," and in others to "phase." As regards the efficiency of transformers working at different frequencies, he thought the comparison ought to be made on different transformers, each designed for the frequency under which it was tested. Under these conditions, and with 50-light transformers, increasing the frequency from 42 to 83 raises the efficiency from 92 to 93 per cent. when worked at full load all day, and from 60 to 62 per cent. when working at full load for two hours out of the 24. From some recent calculations he found the loss from eddy currents in direct-current armatures to be unimportant when thin plates were used.

Prof. S. P. Thompson, speaking of arc lamps, announced that he had recently localised the back E.M.F. in direct-current lamps, and found a sudden change in potential of 39 volts at the crater. He questioned Mr. Kapp's statement about the field-magnets increasing the self-induction of the armature, for the time was too small (about $\frac{1}{200}$ second) to allow such masses of iron to change their magnetism in obedience to the armature current. Prof. Thompson also gave a graphical construction for showing the distribution of work between two machines of different voltage when switched in parallel.

Prof. Ayrton, having obtained measurements of the self-induction of Mordey armatures by the secohmmeter, was in a position to say that neither Mr. Kapp or Dr. Thompson were quite correct, for the coefficient was 0·038 in position A (*see* Fig. 5) and 0·036 in position B; and both decreased about 14 per cent. when the magnets were fully excited. The frequency of the testing currents was about 100 in all the tests. From experiments recently made at the Central Institution on the efficiency of the Mordey transformer, with frequencies varying from 53 to 240, he said there is no evidence of greater efficiency for medium frequency; on the contrary, the efficiency increases with the frequency, particularly for small loads, and is nearly the same for all frequencies at the maximum working load.

Prof. Forbes thought the fact of the engines driving the alternators when the experiments were made being ungoverned, should be clearly stated in the paper, for this helped considerably to explain the phenomena. He also believed Mr. Mordey was perpetuating an error if he assumed that only two methods of distribution were possible—either separate large machines, or small ones in parallel; but it was quite common in America to divide the mains, and connect them to separate machines, when necessary, and the circuits are so arranged that two or more may be switched on one machine during the hours of minimum demand.

The **President** (Sir W. Thomson) suggested the expression "cophasedly synchronised," as meaning that the machines were in step both as regards phase and speed. To explain the result of coupling two alternators at 1,000 and 2,000 volts respectively, he considered the current resolved into two components, differing by a quarter of a period, and having their respective maxima at the position A and B in the above figure. The latter component would tend to magnetise the motor-fields and to demagnetise those of the generator, and in this way produce the observed phenomenon. Referring to the single-coil alternator, he thought it a beautifully simple and ingenious machine, and though some loss would arise from magnetic friction, this need not be great.

Mr. Raworth, who during the week had made experiments on the E.M.F. curves of alternators and transformers, exhibited a diagram showing the arrangement adopted. The results, though incomplete, were, he said, astonishing, and he thought the question of lag would be settled in a manner not in accordance with theory.

Mr. Mordey, in reply, said Dr. Hopkinson's difficulty arising from the loss in leads was not a serious one, for the high potential used in transformer systems rendered any considerable loss unnecessary. Referring to Prof. Adams's criticisms, he said he had laid no claim to the invention of parallel working, but had shown it to be perfectly practicable at a time when, in spite of the success obtained by Prof. Adams (to which he had drawn attention in his paper), considerable doubt existed as to its commercial possibility. He considered Dr. Fleming's explanation of the minimum generation of heat for mean periodicity a very probable one, and mentioned that, although the heating at periodicity 125 was more than that at 100, yet the current passing through the transformer was less in the first case. As regards Mr. Kapp's difficulty, Mr. Mordey admitted that a change of 500 volts did occur, and although he had not attempted to explain the matter, yet the straight characteristic given by the machine as a generator was a sufficient proof that as a motor the self-induction could not be great. Speaking of Mr. Swinburne's calculations on the loss due to eddy currents, he thought experiment far more satisfactory, and his observations showed the loss to be considerable. In reply to Prof. Ayrton, he said the method of determining the waste in transformers by direct currents was quite safe to use with efficient converters. From Prof. Forbes's remarks, he thought his views on parallel working had been misunderstood, for he did not recommend it under all circumstances, but in cases where all the prime motors and alternators would work without requiring a large margin, it is a great convenience to arrange the leads and mains so that they may be connected in parallel.

CITY NOTES.

Electric Construction Corporation, Limited.—Letters of allotment and regret in this Company have been posted.

Brazilian Submarine Telegraph Company, Limited.—This Company's receipts, for the week ended June 7, amounted to £4,689.

Great Northern Telegraph Company.—This Company's receipts for May were £22,800, making, from January 1, a total of £106,800, against £108,400 and £103,520.

Western and Brazilian Telegraph Company, Limited.—The receipts for the week ended June 7, after deducting the fifth of the

* *Journal*, vol. xvii., pp. 215, 216.

Digitized by Google

gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,230.

Lancashire and Cheshire Telephonic Exchange.—The eighth ordinary general meeting of the shareholders of the Lancashire and Cheshire Telephonic Exchange Company, Limited, was held in Manchester on Tuesday, when a dividend at the rate of 8½ per cent. per annum was declared. The Chairman, referring to the proposed amalgamation of the Company with the United Company, deprecated the opposition of the Postmaster-General, and maintained that the amalgamation would be advantageous to the public.

Companies of the Month.—The following electrical companies have been registered during the past month:

Crompton Howell Electrical Storage, £1 shares	£19,600
Electric Tramcar Syndicate, £10 shares	20,000
Electric Construction Corporation, £10 shares	500,000
Halifax and Bermudas Cable Company, £5 shares	50,000
Jensen Electric Manufacturing Company, £5 shares	80,000
Keswick Electric Light Company, £1 shares	5,000
Liverpool Central Hydro-Electric and Massage Company, £1 shares	500
Medical Battery Company, £5 shares	100,000
Pontypridd Electric Lighting Company, £5 shares	10,000
Portsmouth and South Hants Electricity Supply, £5 shares	50,000

NEW COMPANIES REGISTERED.

Municipal Electric Light and Power Corporation, Limited. Registered by W. Webb and Co., 6, Essex-street, Strand, W.C., with a capital of £25,000, in 2,490 shares of £10 each, and 100 founders' shares of £1 each. Objects: to generate, produce, supply, and use in any manner electric or magnetic currents for the purpose of providing light, heat, motive power, etc. The first subscribers are:

	Shares.
F. White, 30, Crewys-road, Peckham	1
W. Grey, 11, Tissington-street, E.C.	1
E. Day, 22, Canonbury-road, N.	1
F. Julian, 36, Powell-road, Clapton	1
M. Sleet, 75, Shrubland-road, Dalston	1
E. Laming, 53, Lewisham-road, S.E.	1

There shall not be less than three nor more than seven Directors. Qualification, 25 shares of £10 each. The first to be appointed by the subscribers to the memorandum of association. Remuneration to be determined in general meeting.

PROVISIONAL PATENTS, 1889.

JUNE 3.

9153. **An improved dry galvanic battery.** Don Juan Arnold and Harlan Brant Coryell, 52, Chancery-lane, London. (Complete specification.)

9162. **Improvements in the armatures of dynamo machines.** Charles Eugene Lancelot Brown, 46, Lincoln's-inn-fields, London.

9163. **Improvements in electricity meters, or apparatus for measuring electricity, partly applicable for other purposes.** Leslie Bradley Miller, 46, Lincoln's-inn-fields, London.

9166. **An improved electrical repeater and commutator to indicate the normal position and the movements of railway or other signals, slots, and the like.** David Wells, 14, Brunton-place, Edinburgh.

9182. **Improvements in apparatus or devices for switching or diverting electric currents, more especially intended for use with telephonic circuits.** Alfred Graham, 47, Lincoln's-inn-fields, London.

9183. **An improved exciting liquid for electric batteries.** Max Sussman, 45, Southampton-buildings, London.

9185. **Electric safety signalling devices for railways.** Josef Haas, 115, Cannon-street, London.

9192. **A new or improved fitting for electroliers.** William Winstanley Strode and William Davis, 70, Chancery-lane, London. (Complete specification.)

9197. **Improvements in and relating to relays for telegraphic purposes.** Hugo Lubliner, 45, Southampton-buildings, London.

JUNE 4.

9231. **Improvements in the method of and devices for regulating currents generated by shunt wound dynamo-electric machines.** William Edwin Heys, 70, Market-street, Manchester. (Ernest P. Clark, United States.) (Complete specification.)

9237. **Improvements in dynamo electric generators and motors.** George Edensor Dorman, The Hawthorns, Stafford, Staffordshire.

9241. **Electric meters.** Alan Archibald Campbell Swinton, 66, Victoria-street, London.

9258. **Improvements in electric signal lamps and appliances connected therewith.** Frederick Lawrence Rawson and William Stepney Rawson, 11, Queen Victoria-street, London.

9284. **Improvements in metallic telephone circuits.** Henry Lyman Burbank, 53, Chancery-lane, London.

9294. **Improvements in and relating to dynamo-electric machines and electric motors.** Henry Harris Lake, 45, Southampton-buildings, London. (Charles S. Bradley, United States.)

9300. **Improvements in and relating to dynamo-electric machines.** Henry Harris Lake, 45, Southampton-buildings, London. (Hermann Lemp, United States.) (Complete specification.)

9304. **Improvements in switches for electrical purposes.** Wm. Barnicoat, 17 and 18, Southampton-buildings, London.

JUNE 5.

9350. **Improvements in dynamo-electric machinery.** John Johnson and Frederick Russell, 68, Gaisford-street.

9352. **Improvements in electrical horology.** Fernand Espir, agent for Paul Klotz, 3, East India-avenue, London, (Ludovic Belzon fils, France.)

9376 **Improvements in miners' electric lamps.** Henry Inkson Harris, 21, Cockspur-street, London. (Complete specification.)

JUNE 7.

9440. **Improvements in ceiling roses for suspending electric lamps and other electrical purposes.** Edward William Johnstone Macdonald, Bow Electric Works, Arnold-road, Bow. (Complete specification.)

9445. **Lightning arresters for electric conductors.** James Waring Sec, 52, Chancery-lane, London.

9456. **Improved method for preventing fumes from secondary batteries.** Bernard Mervyn Drake and John Marshall Gorham, 2, Princes-mansions, Victoria-street.

9461. **Improved composite electric omnibus.** Daniel McIntosh Reid, 41, Lamont-road, Chelsea, London.

JUNE 8.

9509. **Improvements connected with electrically operated coal mining and drilling machines.** Elmer Ambrose Sperry, 1, Quality-court, Chancery-lane. (Complete specification.)

9528. **An improvement in telephony.** Henry Coles, 15, River-street, Myddelton-square.

9537. **Improvements in incandescent electric lamps.** Illius Augustus Timmis, 2, Great George-street, Westminster.

9541. **Improvements in appliances for attaching telegraph and other wires to insulators and similar uses.** Frederick Lindley, 3, Poet's-corner, Westminster.

9552. **Improvements in electric meters.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

9571. **Arrangement of circuits and apparatus to be used in connection with telephonic communication.** John Edward Kingsbury, 24, Southampton-buildings, London. (Francis Raymond Welles, Belgium.)

9576. **Improvements in and relating to incandescent electric lamps.** Henry Harris Lake, 45, Southampton-buildings, London. (Silvanus Frederick Van Choate, United States.) (Complete specification.)

NOTES.

Prof. Houston.—We understand that Prof. Houston has gone over to Paris, but will return to London later on.

Deptford.—A number of the American engineers now on a visit to this country and to the Paris Exhibition, were shown over the Electric Lighting Works at Deptford on Wednesday.

Blackpool Electric Tram.—On Whit Monday, the number of passengers carried on the Blackpool Electric Tramway was over 11,000, and the receipts exceeded £87, and recollect this was without cruelty to horseflesh.

Glass Insulation.—The method of laying underground wires by placing them in glass tubes protected by a layer of cement, and surrounding the whole with an iron pipe, is said to give a high degree of insulation, and to be watertight. It seems to us, however, to possess several palpable drawbacks.

Electric Sugar Fraud.—Mr. Howard, one of the persons alleged to be implicated in the electric sugar swindle, has been found guilty of "grand larcency" by the jury, and sentence will be pronounced in due course. Such is the New York telegram. Would that some of the men on this side also had their deserts.

Royal Military Tournament.—All the badges used at the above tournament by H.R.H. the Prince of Wales, H.R.H. the Duke of Cambridge, and all the officers and gentlemen composing the various committee, also judges, staff, and competitors, have been made by the Endolithic Ivory Company, Pomona-buildings, Fore-street, E.C.

Derby.—The central installation of Messrs. John Davis and Son seems to bid fair for success. The boiler for this installation has been supplied by a local firm, Messrs. Walley and Sons, the engine by Messrs. Marshall and Sons, and the dynamo by Holmes and Co. As the current to the lamps is from accumulators it is always available.

Felten and Guilleaume.—Referring to our paragraph *re* Mulheim cables, we are informed that Messrs. Felten and Guilleaume are manufacturing a sample half-mile of Ferranti cable for the company with which Mr. Ferranti is connected, and which is similar in construction to the short samples already submitted, and which gave excellent results.

Electric Hoist.—Messrs. Drake and Gorham are paying considerable attention to the application of electricity for motive power in private houses and offices, and have been very successful in their application of electricity to working electric lifts for banks, etc. Those which they put down last year are all working successfully, and the cost of maintenance is found to be extremely low. We are informed they have now received instructions to fit up a somewhat larger lift for the Bank of England, which is to be ready for use in the course of the next month.

Company Promotion or Progress.—We have received from the Secretary of Elmore's Patent Copper Depositing Company, Limited, a criticism on our statement on this subject in our last week's issue. The writer says that the Copper Depositing Company was formed about four months ago, and will soon be in a position to demonstrate from its actual output the value of the process. He also informs us that our figures at the close of the paragraph are incorrect, and refers us to Messrs. Woodhouse and Rawson to be put right, yet our figures were those supplied by the writer himself.

Electro-Plating.—*Ironmongery* says: "There is in many branches of the hardware trades of the Midlands a splendid field for enterprise on the part of makers of electro-plating apparatus. Day by day the process of electro-plating is entering more largely in the hardware branches, in which a high degree of finish is desirable. If an apparatus of simple description, and moderate in price, for occasional use only, were brought under the notice of the hundreds of small manufacturers who abound in this district, no doubt a large trade would be done, as having electro-plating 'done out' is too costly an experiment to be very largely adopted."

St. Martin's-in-the-Fields.—Messrs. Gatti have sent a letter to the Vestry stating that they are able to supply electricity in the district to the extent of 8,000 lamps of 16 c.p., and can extend it shortly to 30,000 lamps. Mr. Laing said that he and Mr. Prescott, together with the surveyor, attended before the Board of Trade and opposed the idea of any one company having a monopoly, which Mr. Courtenay Boyle endorsed. He would move that Messrs. Gatti have the same facilities as the two companies. Mr. Prescott seconded the motion, which was supported by Captain Probyn, who said that Messrs. Gatti were able to supply 7,000 lamps. The motion was carried.

Specimens of Wire.—We have received from the Telegraph Manufacturing Company an exceedingly neat and handy case of their wire. Some 50 or 60 samples are contained in the case, and the samples, being on cards, can be easily taken out and replaced by new ones. Of course, there is much more to be thought of when purchasing covered wire than can be shown in samples, though after experience with the make, orders might be freely given after inspecting such samples. However, the production of such a case as this shows that the company is endeavouring to provide for the wants of customers, and are pushing forward for business.

Royal Society.—The June conversazione was held on Wednesday last. At this reception it is well known that ladies are present, and this adds to the gaiety, and probably brings the evening more in accordance with what a conversazione is generally understood to be. Among the various exhibits, we may mention that Colonel Gouraud was to the fore with Edison's phonograph. Prof. Silvanus Thompson exhibited his acoustic apparatus, illustrating polarisation of light, while Messrs. Mond and Langer showed a new form of gas battery, said to be an improvement on that of Grove. The assembly numbered some seven or eight hundred, and included almost all the best-known names connected with science.

Another New Company.—The transference of the well-known electric machinery, lamp, and apparatus manufactory of Mr. S. Schuckert, Nuremberg, to a company under the title of Schuckert and Co., Commandit-Gesellschaft, as we learn from a circular sent out, was accomplished on the first of April. In addition to the Nuremberg business and its branches at Leipsic, Cologne, and Breslau, the Münchener Commandit-Gesellschaft fü elektrische Beleuchtung und Kraftübertragung S. Schuckert and Cons. has also been taken over by the new company. The members of the late firm, Mr. S. Schuckert and Mr. Alexander Wacker, will devote their personal attention to the new company.

Digitized by Google

Gillingham.—At the last meeting of the Local Board, a letter was read from the local electric light company stating that as the Board of Trade had intimated that statutory powers should be obtained for placing mains underground instead of overhead, the company begged to inform the Board that application was intended to be made on or before December 21 next, by memorial to the Board of Trade, for a provisional order to be confirmed in Parliament in the ensuing session, whereby it was proposed to authorise the company to apply electricity for any private or public purposes within the district of the Gillingham Local Board. Mr. Mackey supposed the Board would not offer any opposition to the application. The chairman replied that there was no intention of proceeding with any formal proposition.

St. James.—A letter from the Metropolitan Electric Supply Company was read to the Vestry, stating that they are gratified at the position that the Vestry has taken on their behalf, and adding that should they be so fortunate as to obtain a provisional order for this district, they will always do their best to meet the wishes of the Vestry in every way in their power; also one from their solicitors, stating that the company will use every means in their power to induce the Board of Trade to include this parish in their district, and that they believe they can supply electricity on well tried and established principles effectively to the parish from stations which the company have acquired in reliance on the parish having been granted to them by the Board of Trade last year, and the support of the local authority.

London County Council.—At the last meeting of the Council, the chairman stated that a letter had been received from the Board of Trade thanking the Council for the assistance it had given in the matter of electric lighting, and sending a copy of a model order proposed to be followed in the case of all the electric lighting applications now before the Board of Trade. This letter will be reported by the Highways Committee probably at the next meeting of the Council. In the meantime the Board of Trade stated that if the Council wished to bring any points in the order under the notice of the Board, the Board would be glad to see representatives of the Council, and to discuss such points with them. Perhaps the Council would authorise the Highways Committee if it should think necessary to depute to representatives to confer with the Board of Trade, and to suggest, on behalf of the Council, any alterations they might think desirable.

Inspection.—Mr. Land, in our American contemporary, *The Electrical World*, makes a suggestion which also meets with editorial approval in that paper. The author of the suggestion has visited several hundreds of lighting stations in the smaller towns, and has noted many imperfections which exist, and he suggests the imperative need of a competent general inspector. He thinks that the cost of such inspection should be borne by the various companies, and that the inspection would lead to improved service, and thus to greater economy. From a cursory examination of this question, we doubt altogether its feasibility. It seems to us that the weak point is not after the installation is started, but when the installation is being designed and before it is commenced. The superintendence wants to be close during the carrying out of the installation, to see that the workmen do their work properly and to see that the design is faithfully followed; but there may be something to be said for such a system, although we cannot at present see it, hence we refer to the suggestion for what it is worth.

Electric Lighting on the "Exmouth."—A report upon the subject of the electric lighting of the training ship "Exmouth," the vessel which took the place of the ill-fated "Goliath," destroyed by fire some years ago, was read at the last meeting of the Whitechapel Board of Guardians. The managers, the report stated, were anxious to secure the best form of lighting, not only as regards economy, but also as regards safety. Three years had elapsed since the electric lighting of the ship had been completed, and the managers had come to the conclusion that the approximate annual cost of such system was £665, while the annual average cost of lighting the ship by means of colza oil during a similar period was £680. A positive saving had thus been effected, besides obtaining a greater security from fire, together with other advantages, including the greater cleanliness and extended opportunity of training the boys in all parts of the ship, irrespective of atmospheric conditions, so that the actual cost of the electric light could only be regarded as approximate.

Lucerne.—The public electric light installation at Lucerne, says *Industries*, was inaugurated on the 25th ult. The town had already a central station for the supply of electricity to private customers, and now a very fine display of arc lamps, for the illumination of the quay and principal streets, has been added. The financial part of the work was undertaken by a private company, and the technical part was carried out by Messrs. Troller Brothers, who were the first to introduce electric power and light plant in Lucerne. For the street lighting there are provided twenty-two arc lamps, fixed on ornamental iron posts, and the town pays the company for the light supplied at the rate of £16 per lamp per annum.—In response to an invitation from the town authorities of Zürich for tenders for a central electric light station, nine tenders have been received, of which five are from Swiss and four from foreign contractors. Amongst the Swiss firms who tendered are the Zürich Telephone Company and the Oerlikon Works, and amongst the foreign firms are Messrs. Siemens and Halske and Messrs. Crompton and Co.

The Military Tournament.—Electricity plays its part in the entertainment which is now annually held at the Royal Agricultural Hall under the title of the Royal Military Tournament. A full dress rehearsal of the tournament was held on Wednesday when a realistic scene was rehearsed The southern end of the hall has been prepared, and presents a place of arms with its outworks. Across the hall, from north to east, is laid a river, with its banks. A cyclist corps comes as skirmishers, and signal the general advance. All is done with realistic force, and in due order a division advances to the attack of the fortified position, the division including infantry, a Bianconi car, a Maxim gun on field carriage, a horse artillery gun, a Hotchkiss revolving cannon, in the hands of the Field Artillery, who are considerate enough not to fire it even with blank cartridge, a Royal Engineers' bridging battalion, and medical staff, these formed of the useful Volunteer Medical Staff Corps. The Royal Engineers build a bridge with all celerity. The bridge built, the attack commences, and the enemy brings out the Hotchkiss gun, mounted on an armour-plated electric wagon. The work on both sides is well sustained.

Leeds.—A meeting of the Electric Lighting Committee of the Corporation, Mr. L. Hardwick presiding, was held recently to consider the report of Mr. Hewson, the borough

Digitized by Google

engineer, in reference to electric lighting in Leeds. The report was considered at great length, and it was agreed to adopt the recommendations it contained in reference to the lighting by electricity of the Council Chamber, the Courts of Justice, and the offices in the Town Hall and the Municipal Buildings. The proposal as to the establishment of a central electric station upon the "Midden" was deferred to a future meeting. As a result of the committee's action, the arc lamps in the Victoria Hall will be removed—assuming, of course, that the Council offer no objection—and will be replaced by incandescent electroliers. It is proposed that the arc lamps shall be fixed in the streets surrounding the Town Hall. It is estimated that over 2,000 lamps will be required to illuminate the Town Hall and Municipal Buildings, and that the scheme will cost £3,000. It is also proposed to ask the Corporation to apply for a provisional order to supply electric light generally. The estimated expenditure under the order is £68,000.

Taunton.—Mr. B. A. Wood writes the following letter to the *Somerset Express.* We give the letter as showing, not perhaps literary excellence, but that the electric light is appreciated, and, once adopted and fairly installed, those who use it once urge its extension. "The wonders of the electric lamp excel the anticipations of its most sanguine friends. The brilliancy and steady flow of its light leaves the glimmering and fitful flame of the old-fashioned gas-post far behind. The universal adoption of this beautiful, efficacious, and safe method of illumination cannot be far off. Science has, indeed, perfected at last one of the most useful discoveries, tending to the comfort and enjoyment of life, in these wonderful times. Darkness is abhorrent to nature; vegetable and animal existence—alike sleep it away. The modest daisy folds up her bosom within her protecting nightcap and retires to rest, joyfully welcoming the return of light. The lark 'from his moist cabinet' greets the return of morning, but man has now created for himself universal day and will forget his hour of rest, while 'nature's sweet restorer' will be less than ever necessary to his enchanted existence. Let us hope that the presiding genii of this 'wonderful lamp' 'at whose bright presence darkness flies away' will extend his radiant influence to some of the side streets."

Light and Power.—The *Transactions* of the Chesterfield and Midland Counties Institution of Engineers just issued, contains a paper by Mr. Winstanley Wallis dealing with electric lighting and transmission of power in mining. The author gives a list of English collieries at the present time using electric light. The total number is 42, and of these 6 are in Derbyshire, 3 in Durham, 3 in the Manchester district, 3 in Northumberland, 1 in the North Wales district, 20 in South Wales, 7 in Staffordshire, 3 in the Wigan district. There does not seem to be many installations for the transmission of power. The author refers to the well-known ones at Trafalgar Collieries in the Forest of Dean, and at St. John's Colliery, Normanton, so far as England is concerned. We are glad to see that the author objects to the cry of "Wait for further improvement." The electric light at the present moment is far better than any other, and there is little margin for improvement in the small installations such as are used in colliery work. One paragraph we may quote here: "It should be noted, said Mr. Wallis, that collieries possessing an electric light plant are in a position to adopt electric safety lamps at a small outlay, referring, of course, to lamps using storage batteries, such as the Edison-Swan, Pitkin, and others, as it is not probable that lamps with primary batteries will be extensively used till zinc costs as little weight for weight as coal."

School of Electrical Engineering.—Examinations for the certificate of this school have recently been conducted by Mr. Gisbert Kapp, A.I.C.E., and Mr. Kempe, of the Engineer-in-Chief's Office, General Post Office. For the certificate in electric lighting and power transmission, Mr. Kapp set a paper in mechanical and another in electrical engineering, and he devoted many hours to practical and *viva voce* examination of the students on (to quote his report to the managers) "steam-boilers, arc lamps, calibrating, resistance-measurements, jointing, photometry, switches and management of circuits, and practical use of graphic methods as applied to dynamos." A minimum average of 70 per cent. of full marks in the practical work, and of 60 per cent. in each of the two papers is a necessary condition of obtaining the certificate. Of eleven students at the practical examination, only three failed to exceed this minimum. Certificates in electric lighting and power have accordingly been awarded on Mr. Kapp's report to the following gentlemen: Messrs. Wm. J. Alexander, G. Horley, T. Raaschon, F. Wallis. Mr. H. R. Kempe set two papers, one upon electrical testing generally, and the second containing special and practical questions upon telegraphy and telephony, in which a minimum of 70 per cent. of full marks was required. As the result of his report, certificates in these subjects have been awarded to Messrs. W. St. J. Beale, H. C. Moberley, and H. H. Paynter.

Royal Agricultural Society.—The Jubilee Exhibition of the Royal Agricultural Society opens to-morrow in Windsor Great Park. A glance through the catalogue shows that there are a great many exhibits which should be interesting to electric light engineers, principally connected with engine-building. We may point out, however, that the electric light engineer often has to erect temporary buildings quickly, and perhaps an investigation of the yard at Windsor would show many different ways of doing this. With regard to the engines, we notice that at Messrs. Robey and Co.'s stands, Nos. 1 and 361, that out of the 16 items in this firm's exhibits, nine of them relate to engines, while Messrs. John Fowler and Co., at No. 4, show seven of their engines. Stand 58, is that of Messrs. Dennis and Co., the well-known agents for Messrs. Felten and Guilleaume, who exhibit wire, etc. Stand 64 is that of Messrs. Willcox and Co., who exhibit belting of various kinds, engine-packing, lubricating oils, and engineers' sundries. At stand 74 Messrs. Immisch and Co. show an electric carriage. Stand 275 is that of Messrs. Ransomes, Sims, and Jefferies, who have a very large exhibit, amongst which will be found seven of their well-known make of engines. At stand 316 Messrs. Ruston, Proctor, and Co. exhibit engines of various kinds—portable, horizontal, semi-fixed, and vertical. At stand 371 the British Gas-Engine Company show a number of their gas-engines, which engines are becoming more and more popular, and especially so since the trials before the Society of Arts. Advertisements referring to the manufactures of these various firms will be generally found in our advertisement pages.

Electrical Census Machine.—This system of machines may be described as follows: The census collector will call with his printed blank, and answers to questions will be written in the usual way. These sheets will then

Digitized by Google

be placed before a person who operates a machine which may be likened to a type-writer, except, instead of the usual ink mark on paper, small round holes are punched in a card. The cards, one for each person, are about 6½ inches in length by 3 inches in width, and the particular position of a hole in a card indicates an answer to some of the questions in the printed blank. As many as 250 items of information can be punched out upon a card, although no one card would ever have more than one-tenth part of the whole number, as, for example, no one person can be classed as both white and black, American and foreign born, and if foreign born he can only come from one country. These cards when punched are placed one at a time in a sort of press, and a lever operated by one hand is brought down, when a series of pins are brought against the card. Whenever a hole has been punched in a card the corresponding pin passes through into a mercury cup beneath, completing an electric circuit. These circuits, one for every hole, pass out to a large number of counters which operate electrically, and which add upon their dials all items of the same kind upon the same dials; as, for instance, all white men upon a dial marked white males; all business or professional people upon dials which indicate their particular business or professions. The cards, as they leave the press, are all sorted by means of an electrical sorting device, whereby they may be separated into groups or States of the Union. It will thus be seen that the machines are much more reliable than the most accurate human agency, and that one machine will do the work of a large number of clerks. The next census of this country will be taken with these machines, and two will be sent to New York soon for the 1890 census taking.—*Scientific American.*

Electrical Launches.—A new electrical launch, called the "Pioneer," has been especially designed and built for Mr. Andrew Pears by W. Sargeant and Co., launchbuilders and electrical engineers. The vessel was launched on Saturday, the 15th inst., before a large and enthusiastic audience, from the builders' works, Strand-on-the-Green, Chiswick. The boat is 40ft. long, with 5ft. 8in. beam, and designed to carry about 20 passengers, with a mean draft of 18in. The boat has a displacement of 5¼ tons. The speed is about seven miles an hour. The electrical apparatus is placed below the seats fore and aft, leaving a clear run the whole length of the launch. In the centre is a handsomely fitted cabin executed in bright teak, as are all the other fittings throughout. The hull is constructed of three skins, the inner being diagonal, with outside planking of bright mahogany in narrow widths. Deadwood aft has been entirely abandoned with the object of assisting the steering in narrow water, besides giving a clear run and obtaining greater efficiency from the propeller. The rudder, on an entirely new principle, is cast in Delta metal, with the object of clearing weeds, obviating sternpost, deadwood, and gudgeons, with facilities for quick removal and easy steering. The steering wheel is situated in the front part of the cabin, on the port side. The lead-lined compartments are arranged to receive sixty E.P.S. accumulators, 1889 type, placed in ebonite boxes. The midships section of this craft being perfectly flat, in the event of her taking the ground the acid will not slop over; and the construction is similar to the "Viscountess Bury," 65ft. by 10ft., also built and designed by W. Sargeant, which was launched in October. The motor is a 6in. Immisch machine, which is calculated to develop 6·0 maximum brake h.p., rotating at 1,400 revolutions per minute. Highest E.M.F. 200 volts, lowest 60 volts, half-speed 700, indicating about 3·5 b.h.p. The motor is placed under the floor aft and ventilated. All lights for port, starboard, masthead, and cabin will be incandescent electric lamps supplied direct from the accumulators; ammeter and voltmeter will be placed in front of the wheel and in sight or control of the steersman. All the machinery and power being placed under the seats and floor, leaves a clear space from stem to stern. The windows are of engraved plate glass, with teak folding doors leading into after-cabin, which is open on the port and starboard side. The "Pioneer" will be at Henley Regatta.

Woodhouse and Rawson.—This firm is appointed to the sole agency for the sale of a book, entitled "The Electric Railway," by Fred. H. Whipple, of Detroit. With this notification we have also received a small catalogue of Mr. Whipple's, which has a couple of pages devoted to suggestions, in the following strain: "If you are thinking of purchasing electric light machinery, always take advice from an electrical engineer as to what is best adapted to your needs. A great many plants are put in that do not give satisfaction, because they are of the wrong kind, or are too small. A person writes to a company that he wants a plant of a certain size, and the company puts it in, supposing that he knows what he needs. He, perhaps, finds that it does not suit him, that it ought to be arc light instead of incandescent or *vice versâ*, or that it is too small, and he condemns electric light as a consequence. Sometimes it is the agent who does it. How much better to go to a competent man, one who has experience and judgment, and who can advise as to what is needed, and save trouble. The construction work is as important as the machinery, and should be planned properly. If a man builds a house he generally consults an architect. If he is putting in an electric light plant why not consult an engineer? The difference between the various makes of electric machinery is similar to the difference between different makes of engines, in details and points of excellence and not in principle, and 'companies' are only manufacturers of machinery. Whatever you do, do not buy cheap electric light machinery. With some kinds of machinery it is impossible to get results which will do, even if cheap and inferior; but to get what is wanted—a good and economical light—it is necessary that the machinery be perfect, and therefore somewhat expensive. Do not buy machinery which is experimental, but take only that which has an established reputation. If you wish an estimate, send a sketch of your town, showing your opinion of the location of the lamps. Show the location of the proposed station, and state the kind of power you have, or whether power is to be put in also. If it is incandescent lighting, say whether the buildings are wood, stone, brick, or iron, and wet or dry, and also whether the wiring is to be surface-wiring or concealed. Competent engineers sent to any locality on a moment's notice. Plans and specifications prepared, and plants laid out in a first-class manner. If you want cheap work, do not invite us. We advise nothing but the best."

Edinburgh.—In connection with an exhibition of electrical engineering and mechanical inventions which is proposed to be held in Edinburgh, in the spring of next year, to commemorate the opening of the Forth Bridge, a deputation waited on Lord Provost Boyd in the City Chambers on June 13th at noon. The deputation consisted of Principal

Digitized by Google

F. Grant Ogilvie, Heriot-Watt College; Mr. A. R. Bennett, general manager for Scotland of the National Telephone Company; Mr. David Allan Stevenson, C.E.; Mr. G. W. W. Barclay, Mr. Mitchell Thomson, Mr. John Harrison, and Mr. George E. Watson, C.A., interim secretary. Treasurer Clapperton introduced the deputation to his Lordship, who was accompanied by Bailie Walcot. Mr. Bennet made a statement regarding the scope of the exhibition, for which the patronage and support of the magistrates and Town Council were desired. After some remarks by other members of the deputation, the Lord Provost expressed his willingness to give the matter his most favourable consideration. A large and influential committee has been formed for the promotion of the exhibition, including Professors Tait, Armstrong, Chrystal, and Crum Brown, the Lord Justice-Clerk (who is to be an exhibitor), Mr. W. H. Preece, Chief Electrician G.P.O., Sir Thomas Clark, Mr. J. R. Findlay, Mr. Robert Cox of Georgie, Mr. W. B. Blaikie, and some of the principal engineers and officials connected with the Forth Bridge. It may be mentioned that the exhibition is proposed to be held in a field at Meggat Land, in the neighbourhood of Merchiston, which is very easy of access by tram and rail; and, that should the exhibition be proceeded with, it is not unlikely that the convention of telephonic and electrical engineers might be held in the city at the same time. The following reasons are given for holding such an exhibition: (1) The completion of the Forth Bridge, which is likely to bring to Edinburgh a considerable influx of people specially interested in the branches and knowledge which the suggested exhibition is primarily intended to illustrate. (2) There never has been an exhibition of electrical engineering in Scotland before. (3) The combination of mechanical inventions, with electrical engineering, is likely to open an interesting field to all visitors. (4) There is no topic which is exciting wider interest than practical electricity, capitalists, small investors, men of science, and young men choosing a profession, are all looking towards it as a chief factor in business life. It is daily becoming more and more a convenient agent, even in household affairs, so that everyone is eager to form acquaintance with the many recent electrical inventions. (5) The space for the comparatively small electrical exhibition to be held this year in the Bingley Hall, Birmingham, has already been greatly over applied for.

The Telephone Controversy.—The following letter has been sent by the United Telephone Company in answer to that of Sir A. Blackwood, given in our issue of June 7, page 463: "Sir,—I am instructed by the directors of the United Telephone Company to acknowledge the receipt of your letter of the 4th inst. The directors are much surprised at the statement made by the Postmaster-General, that the amalgamation of the companies was not contemplated when the licenses were issued. It is impossible to suppose that the legal advisers of the Post Office were ignorant of the fact that it is competent for a company registered under the Joint Stock Companies' Acts to liquidate and sell its business to another company similarly registered. Such an arrangement is one of almost daily occurrence, and if there had been any intention or desire on the part of the Postmaster-General, when these licenses were granted, to interfere with such an arrangement, the obvious course would have been to have inserted a clause in the license restricting the company's ordinary rights in this respect. The directors desire respectfully, but firmly, to join issue with the Postmaster-General on the question of fact. Even if the license had been silent on the subject, it would have been impossible to suppose that the legal advisers of the Post Office had overlooked so obvious a point. But, as a matter of fact, the purchase by one company holding a license from the Postmaster-General of the telephone exchange business of another company holding a similar license was contemplated, and the license contains clauses (the precise wording of which was the subject of considerable discussion at the time) providing for the consequences which are to happen upon the sale by a company of the whole or of a part of its exchange business. One of these provisions (drawn by the solicitor of the Department, and inserted after the license was in type) requires that seven days' notice of any such sale shall be given to the Postmaster-General. How, under these circumstances, it can be said that the possibility of such a sale was not contemplated when the licenses were issued the directors are at a loss to understand. The Postmaster-General must surely have overlooked the fact that on three distinct occasions since the granting of these licenses, companies or persons holding licenses to carry on the telephone exchange business have transferred their exchanges to other companies holding similar licenses without the slightest objection being raised by the Postmaster-General. In all these cases the sale was by a competing company to a company working under the United Telephone Company's patents. In the present case (as the Postmaster-General is aware) there is and can be no competition between the companies uniting because, although each company has a license from the Postmaster-General, which entitles it to carry on the exchange business in any part of the United Kingdom, each company, by agreement with the others, works only in its own district. This fact was well known to the Department at the time the licenses were granted. The directors, therefore, fail to understand to what the Postmaster-General refers, when he speaks ot the state of things likely to result from the proposed amalgamation. The union will not affect the question of competition between the companies one way or the other, while it will undoubtedly lead to increased economy and efficiency in working. In objecting to the exercise by a joint stock company of its undoubted right to transfer its business to another company the Postmaster-General is seeking to impose upon the telephone companies the restrictions of a parliamentary company without any of its privileges. As the Postmaster-General is aware, the United Telephone Company has more than once applied to Parliament for incorporation upon the lines recommended by the Parliamentary Committee which investigated the matter and reported in the year 1885, but the Postmaster-General has consistently opposed these applications. The directors ventured to suggest that the interests of the public would be better served if the heavy tax imposed by the Department upon telephonic communication (a tax which is obviously really paid by the public in the shape of increased charges) were removed, and reasonable facilties were granted to the telephone companies, which would enable them to give to the public a cheaper and a better service. The directors have loyally carried out the engagements which they entered into with the Department when the terms of the present license were, after much consideration, settled by the late Mr. Fawcett, and they are unwilling to believe that the present Postmaster-General will attempt to reverse the policy of his predecessors or to withdraw from any assurances, honourable or legal, given by the Department."

THE PARIS EXHIBITION.

I.—GENERAL REVIEW OF EXHIBITS.

The great Exposition Universelle at Paris is now open and in full swing in every department, and no one need hesitate any longer to cross the Channel from the fear of being too early to properly inspect what is to be seen. To the electrical engineer this Exhibition will be thoroughly interesting, not so much perhaps because of great surprises or new developments—though the Exhibition is not without important novelties in electrical work—but for the very thorough manner in which the possibilities of electric lighting have been taken advantage of, both for the complete lighting the whole of the buildings, and for the magnificence of the effect of the decorations and illuminations, as well as for the indications which are apparent of the progress of electrical engineering in all the heavier departments of applied science.

As already announced, our intention is to publish the description of the electrical exhibits at the Paris Exhibition in French and in English in parallel columns, a method which will make it interesting and useful alike to the Continental as well as to the English and American exhibitors, and will serve at the same time to enable these latter to better introduce and describe their goods to the French visitors at the Exhibition. A special edition of the journal will be sent to the Exhibition for distribution amongst the exhibitors and their clients, and copies will be obtainable without charge by those desiring them at the stalls of the principal English and American electrical exhibitors.

Before describing the machines and exhibits in detail, it will be well to give some general idea of the Exhibition and of the electrical section in its main features, for every visitor will at first wish to look round and to take the main bearings of the place before commencing a thorough inspection of the exhibits in which he is particularly interested. Our technical readers will excuse us while we mention in a few words the beauties of the Paris Centenary Fête. Of the arrangement of the Exhibition itself too much praise cannot be said. Beautifully designed and admirably carried out, the buildings are a marvel of beauty and of interest, everywhere the most elaborate finish, the most artistic *tout ensemble*, alike pleasing to the eye as provocative of wonder that so complete and artistic architectural and decorative work should be expended upon a temporary erection. Buildings, apparently fit almost to vie with St. Paul's in size, and with Italian churches in detail of façade, are surrounded with gardens laid out with all the skill of the best landscape gardeners, furnished with central electric lighting stations of thousands of horse-power capacity, which are completely fitted in separate buildings, having marble switchboards, glazed mechanical regulators, and a complete system of underground mains. Throughout the dozen separate buildings Arabs, Egyptians, Servians, and other nationalities mix with the French, English, and American visitors, and throng the gardens, around which at night the arc lamps in profusion glitter among the trees, and the Edison lamps in thick rows fringe the grass plots, and surround the buildings. The illuminations are arranged, not, as with ours, simply in straight lines, but in curves, twists, crescents, and studied artistic effects, for which the French always bear the palm. The luminous fountain at night, shot with lovely and variegated colours, draws rounds of applause from the assembled crowds, who watch its dancing rainbow spray or drops glittering in the beams of the subterranean arc lamps, while above, away up in the sky, a long flare of light stretches away from the lighthouse projector to the very outskirts of Paris from the summit of the Eiffel Tower.

The Eiffel Tower is, of course, the great feature of the Exhibition, and dominates the whole scene, and no notice of the Exhibition would be complete without mention of it. In the daytime one cranes one's neck to see the top of it, while the great arches yawn half across the whole Exhibition ground, and from the second landing even the green country can be seen round the city of Paris. At night the tower is ringed with light from rows of lamps outlining the immense arches, while above the long projector-flash slowly revolves.

At the other end of the grounds, stretching from side to side, is the immense Palace of Machines, the largest building under one roof in the world, and it is here that the exhibits interesting to electrical engineers will mostly be found. The building is so large that it dwarfs everything within it. Those little arc lamps away in the roof are, in reality, large Crompton lamps with globes some 3ft. diameter, and when standing on the ground the lamps can be seen to be a foot or two taller than the workman who is cleaning them. Very neat is the arrangement adopted by Messrs. Crompton for pulling these lamps up and down, as we shall see when we come to describe them in detail. The Palais des Machines is one vast span of 330ft. wide, 150ft. high, and 1,500ft. long; it is crowded in every part with machinery in motion or otherwise, and the engineer visitor might well spend a week in inspecting the exhibits in simply this one building.

Down the middle of this immense concourse of machinery, two wide lines of overhead rails stretch from one end to the other, one on each side of the central aisle. On these run the electric rolling bridge—le Pont Roulant—originally the movable crane to place the machinery, but now fitted with a platform and chairs for 50 or 100 persons, and used to carry passengers from one end of the machinery hall to the other. From these movable bridges the best general idea of the gallery can be obtained, and a ride on one of them—after one o'clock, when the steam is turned on and the machinery is in motion—gives a splendid panorama of the multudinous engines and active machines below. These electric travelling bridges are by Messrs. Megy, Echeverrin, et Bazan, of Paris; they are worked by an electric motor geared by bevel friction-wheels, and appear to be extremely efficient in action, and very easy to manipulate.

Just outside the Palais des Machines is the central electric light installation, for which the power is supplied by Messrs. Davey, Paxman, and Co. The same boilers supply the steam power for the machinery in motion in the Palais, and a large underground network of steam-pipes serves to distribute the steam. At one o'clock an immense vibrating whistle or boomer shakes the whole building with its note and the engines start into motion, machinery begins to revolve, and electric lights, arc and incandescent, begin to glow in every direction.

The British section is at the further end of the hall. We notice first Messrs. Crompton's stand, with three large Westinghouse engines driving the Crompton dynamos which supply the hanging lamps for lighting the whole of the British section. Twenty-four of these lamps are of 25 amperes and are run in one circuit in series. Other 79 lamps are of 8 amperes and are run three in series and the circuits in parallel. Just near, on one side, is a magnificent exhibit of electrical instruments, in a fine kiosk to itself, by Messrs. Elliott Bros., and of this exhibit the British Commissioners consider themselves proud, both from the beauty and finish of the workmanship and the completeness of the exhibit. Mr. Ilius A. Timmis shows in working order his simple and effective long-pull magnetic semaphore for railway lines, with repeating indicators for the signalmen, a method which is rapidly achieving great success, especially on new Colonial and South American lines. Messrs. Avery show Snelgrove's electric weighing-machine, an ingenious instrument in which the principle of automatic regulation by means of a double tipping contact energising a motor, is made to advance or retire a weight on a yard-arm, and at the same time setting in motion geared wheels marked with the weights to be read off, thus automatically registering the weight.

The Hermite system of electrical production of bleaching solution, by means of plates filled with platinum gauze electrodes, made by Messrs. Paterson and Cooper, and recently described by us, is shown in one corner. Messrs. Paterson and Cooper's own stand of electrical measuring instruments is close by; next to it, on one side, Messrs. Mayfield's large Wimshurst machine, and on the other, the Globe Electrical Company's mica cut-outs, with switches and fittings, and the Hedges' rotating liquid speed indicator. Messrs. Latimer Clark, Muirhead, and Co. have also a fine stand of instruments, resistances, etc.; and the Eastern Telegraph Company are to the fore with a mouse mill Morse recorder, to be seen in action. The Electrical

Power Storage Company are showing the ingenious apparatus of switches and regulators for accumulator central systems, as adopted at Chelsea; while the India Rubber Company, of Silvertown, Messrs. Fowler, of Leeds, and Henley's Company show cases of samples of cable. It cannot be said that Britain is sufficiently represented to indicate its large share in the advancement of the practice of electrical engineering. The exhibits are certainly very good, but they are small, both in number and extent, as compared with the displays of the 290 exhibitors in the French section. This was to be expected to some extent, the Exhibition being, of course, a national enterprise, but we were sorry to hear that the Brush Company and other well-known firms had not thought it well, or were too busy with paying work, to represent England at the Paris Exhibition. All the more credit, then, to those firms who still show in finish of workmanship and arrangement of power or of lighting what position Britain takes in the electric progress of the world. One other firm well known in this country is well represented by means of its Paris house. We mean Ferranti. Just inside the Trocadero entrance across the river, and before one gets to the Eiffel Tower, is a central station in which the principal dynamo, of 12,000 watts capacity at 2,400 volts, is a Ferranti machine, made by Ferranti, Patin, et Cie., of Auteuil, near Paris, and this supplies a large circuit of both arc and incandescent lamps, extending a distance of some two kilometres.

To go back to the Palais des Machines, we come next to the American section. Here Edison is triumphant. Under Mr. Hammer's skilful arrangement, Edison makes a show which is the largest for any one person in the whole Exhibition, excepting, of course, M. Eiffel. His globe of incandescent lamps 40ft. high stands in the central of the Palais. It is composed of some 20,000 lamps disposed in the form of a large Edison lamp, and will be flashed at intervals at night. An immense Edison dynamo dominates his stand, the largest double-pole dynamo in the Exhibition, while near beside it stands one of the smallest practical dynamos, like Chang and the dwarf. The municipal three-wire system is represented by exhibits of cables and conduits, and by plans of the New York central station, and the illustration of the Edison lamp is carried out by various exhibits, while a large allegorical picture is exhibited, representing a "ghost" of a huge Edison lamp rising from out the windows of the old Edison laboratory at Menlo Park, and throwing rays of light from New York to all parts of the world—England, Japan, Russia, Africa, and South America. Electric meters, electric instruments, and electric pens are shown and, of course, the phonograph is in full blast with a long tail or "queue" of French visitors to listen to the sound of their own tongues. In fact, the endeavour has been to show at least one specimen of every important invention of Edison at this exhibit, and its crowded state indicates its popularity. Not far away the Thomson-Houston systems are exemplified: the celebrated Thomson-Houston arc-lighting system; the incandescent lighting in parallel and in series; the transmission of power; and the greatest of electrical practical novelties, the Thomson system of electric welding. Here might be seen Prof. Elihu Thomson himself enjoying the inspection of his own creations, while Mr. Meech and Mr. Downs entertained Lord Hartington with an exhibition of the welding.

A little way down in one of the cross aisles, superintended by Mr. A. Graner, secretary of the company, is at last in Europe the wonderful Heisler system of incandescent series lighting, which is achieving such marked success in many American towns. The Heisler lamps are 10 to 500 c.p., and can be turned off or on as desired, and are furnished with automatic cut-outs, and a very ingenious automatic regulator near the dynamo inserts resistance or shifts the brushes and keeps the potential constant. On a single line of No. 6 wire the whole lighting of a town's streets, with private or public buildings also, are connected in series, and yet the brushes of the dynamo have no greater difference of potential than 65 volts. We shall probably hear more about this system later on in England. The Sperry dynamo is just by: a machine with a hollow armature and field-magnets, both inside and out. The Sperry electric coal-cutter is shown on the same stand, a tool looking like a kind of noisy demon with a motor inside it, which deals continually violent digs or pecks—here at nothing—but in use, at the coal seams underground. The actual apparatus exhibited has already cut some hundreds or thousands of tons of coal in America. The Bell telephone is exhibited in all detail in the Palace of Industry adjoining; and Professor Elihu Thomson also shows a collection of his various electrical inventions in the same building. In an annexe to the Palais des Machines, the railway carriages find place, and here we find the Thomson-Houston electric street railway cars. The Sprague Company are also to exhibit, but they are one of the few exhibitors who are not yet in their places.

Coming now to the Continental exhibits, there is nothing but praise to be said of the energy and enterprise shown in the bringing of such a vast collection of machinery together, and of the ingenuity and skill displayed in the design and manufacture of many of the machines. Messrs. Sautter, Lemonnier, et Cie., who supply the light for the Eiffel Tower, fill a central position with a building representing the top of a lighthouse fitted with revolving electric light in all details. This is surrounded at the base with ship dynamos, portable installations for war purposes, and dynamos for torpedo boats. Maison Breguet have an immense Desrozier dynamo of 144,000 watts—the new type of dynamo with no copper, but iron wire only in its armature. The original Desrozier dynamo is also shown, and they have also a large and interesting exhibit of other electrical machinery. Messrs. Cuenod, Sautter, et Cie. show a compact six-pole dynamo of 105,000 watts, which has already been sold eight times over; and the Société Alsacienne show dynamos of 500 amperes, constructed with solid steel commutator bars simply insulated in air, which are also greatly admired, and have been sold six times over to a central lighting company. The same company show an immense dynamo coupled direct to an engine with revolving magnets and stationary outside ring armature, of which the copper sections are exposed to the air. Of Parisian companies, the Compagnie Continentale Edison has a large show in the Palais des Machines, besides a complete central station in conjunction with Messrs. Weyher et Richmond and Messrs. Belleville in the grounds. The Gramme Company exhibit dynamos and motors, and Victor Poff has a most interesting exhibit showing the compressed-air system. The Gramme Company have also a central station, the power, as mentioned, being supplied by Davey-Paxman, and they have also a large exhibit of dynamos and motors in the centre of the Palais des Machines. The Société pour la Transmission du Force par l'Electricité has a splendid double dynamo, while the Swiss firm of Oerlikon have a magnificent exhibit of an immense 600-h.p. generator and 300-h.p. motor of the same type, to which power is transmitted.

It will be impossible to mention all the interesting exhibits even thus briefly. We must content ourselves now by alluding to the new dynamo by Rechniewski, whose magnets and armature-core—the whole machine, in fact—are entirely built of iron plates; the Société Electricité et Hydraulique, near Edison's stand, with a turbine and dynamo in a street lamp-post, as used in Liège; Messrs. Serpollet Frères with their inexplodable boiler (this is at the same place as the Ferranti station); M. Paul Cadot and M. Julien with accumulators, the latter with a full exhibit of electric traction; H. Pieper, of Liège, and P. Jaspar, of Antwerp, have large exhibits, all in the Palais des Machines; the Société Cance show their arc lamps, and Gerard his lamps and dynamos; A. de Méritens et Cie. show their lighthouse dynamos and arc lamps, and also a wonderful process for destroying microbes in wines or liqueurs by *alternating* currents; M. Trouvé exhibits his motors, lamps, and instruments; M. Guyenet and the Compagnie Electrique show motors as applied to cranes, twist drills, lathes, and pumps. The French Government has sent a large collection of telegraphic apparatus.

Of the engines, we should like to call attention to Galloway's and Davey-Paxman's. The Bémer heat-engine is interesting, driving a dynamo at the very end of the Palais, while the straight-line engine is well worthy of a visit—a 100-h.p. engine in the space of 12ft. by 7ft., and 7ft. high. There are no backings whatever, and the valve has automatic cut-off and variable lead at the same time,

Digitized by Google

regulated directly by the load on the pulley. It is also fitted with a new invention of steel wire belting, made out of rings of steel twisted, rolled, and tempered. The French and Belgian engines form a magnificent collection, and engineers will doubtless spend some time with these, but we have left these in preference to things specially electrical.

It is impossible to see or mention all in one visit. Out of some three or four hundred exhibitors in the electrical section we have mentioned the principal ones, and shall return to these and others that are interesting more in detail. Outside, in the grounds, Messrs. Galloway's electric fountain scintillates and flashes as of old. Above all the Eiffel Tower is outlined against the sky, flashing from the summit in the darkness. All around are myriads of blue and yellow lights. It grows late, the people are going, and we go too.

A PRACTICAL DETAIL OF TELEGRAPH CONSTRUCTION.

The height of the supporting posts in a line of telegraph should be accurately adjusted to the inequalities of the ground to avoid sudden and heavy gradients. This, at all events, is the theory of scientific construction, but the practice, it is to be feared, frequently falls short of this ideal. The "rule of thumb" is followed, and the foreman "trusts to his eye" with more or less success. On high roads or railways in Great Britain it is comparatively easy to attain to some degree of regularity without taking levels, but in uneven, hilly country the assistance of an instrument of some kind becomes essential if the best results are to be attained. A really well-built telegraph line is a pleasing sight when viewed from some eminence as it winds in gentle curves across the valley beneath, and is presently lost to view amid the opposite chain of hills, its wires hanging freely in graceful undulations from supports of suitable height. Not only are we conscious that care has been taken with the "survey," but we feel that every post and every insulator is doing its fair share of the work and no more, the general effect being to secure the maximum of strength and freedom from possible "faults."

As far back as 15 years ago the importance of having some definite system of surveying to work upon was recognised in far-off Japan, and men were trained in the use of appliances of a simple character, whereby it became practicable to approach very nearly to perfection in the construction of cross-country lines. The ever-present bamboos made admirable flag poles, and by having a mainmast and a topmast, so to term them, connected by iron rings whereby the topmast could be slid upwards to the extremity, if need be, of the mainmast, and held in position at any fixed point until the precise height of the flag from the ground could be actually measured off in feet and inches, it become tolerably easy to determine what should be the length of the post subsequently to be erected on any given spot. Five or six men standing at points fifty to sixty yards apart held up these flags, and raised or lowered them a few inches at a time by signal, until the altitudes had been sufficiently adjusted; numbered pegs were then driven in to mark the sites for the holediggers who followed, and all particulars entered in the survey-book.

The writer found in practice, however, that even better results were to be attained by using a rough form of theodolite, and taking levels from peg to peg, after suitable positions for the poles to be erected had been determined by actual inspection. It was rarely feasible to preserve equality in the length of the spans, as so much depended on the nature of the soil, the relative position of the proposed posts to pathways and buildings, and the many other important considerations demanding the attention of the surveyor.

An ordinary theodolite would have taken too long to adjust, but a rough substitute was made for a small sum, by which the levels were ascertained within an inch or two. A small circular table, a foot in diameter, was mounted on a light pedestal, 4ft. 6in. in height. The edge of the table was divided in 360deg. A spirit-level was attached to a sighting tube, and mounted above the disc in such a way as to give both vertical and horizontal movement in a rough imitation of an actual theodolite. One man carried forward this instrument, which weighed only 5lb., from peg to peg, whilst another marched on by similar stages carrying a rod marked in feet and inches. It was the work of a moment to note the amount of rise or fall to the next peg, and simultaneously to note the angle in which the peg beneath the theodolite stood with regard to the one behind it and the one in front of it. By this means not only could the required length of any given pole be calculated to a nicety, but the *angular strain* upon it being also known, the surveyor was able to say what support, in stays or struts, it should receive to enable it to withstand the pressure.

The entries in the field-book took somewhat the form appended:

1 Site of pole.	2 No. of pole.	3 Rise or fall to next peg.	4 Angle.	5 Height above ground.	6 Depth of hole.	7 Sup-port.	8 Remarks.
		Ft. in.	Deg.	Ft.	Ft.	Ply.

The trouble taken at the outset in this way was productive of very satisfactory results, for the native foreman, having been furnished with the figures in columns 5, 6, and 7, was enabled to carry out the surveyor's design with confidence and accuracy.

In a country where native labour alone is available, and that unskilled, it is impossible to leave anything to the discretion of the workman. Every detail must be furnished, "cut and dried" for use. In the case of Japan the men were very intelligent, and accustomed to working on hard and fast lines. They were to be relied upon to adhere to the pattern provided, whatever it might be, without the deviation of a hair's breadth.

At first sight it might be supposed that the use of even the very rough apparatus indicated would be superfluous, and five out of every six of our own men will declare that nothing of the sort is necessary, as they can "guess it near enough." The writer believes that guesswork should be abolished in telegraphic construction as in other fields of labour, and that lines will last the longer and develop fewer "faults" for being built upon some approach to scientific principles.

If this be true of lines of telegraph, surely the argument applies with tenfold force in regard to telpherage. It is of the utmost possible importance that the supports of a line, such as that now in operation at Glynde, should be so adjusted as to reduce the inequalities of the route which it traverses to a minimum, and to effect this something more than the unassisted eye becomes requisite. J. M.

A STANDARDISING LABORATORY.

On Wednesday, a joint deputation of the London Chamber of Commerce and the Institution of Electrical Engineers had an interview with Sir Michael Hicks-Beach at the offices of the Board of Trade, to urge the Government to establish an electrical standardising laboratory. The President of the Board of Trade was accompanied by Lord Balfour of Burleigh, Mr. Calcraft, Mr. Courtenay Boyle, Sir Thomas Blomfield, Major Marindin, and Major Cardew. The deputation consisted of Sir William Thomson, president of the Institution of Electrical Engineers, Lord Rayleigh, Sir Douglas Galton, Sir Vincent Barrington, Profs. George Forbes, Silvanus Thompson, Perry, Hughes, Adams, and

Digitized by Google

Foster, Major Flood Page, General Webber, and Messrs. Crompton, Fleming, Lant Carpenter, Trotter, Kapp, and F. H. Webb, secretary of the Institution of Electrical Engineers.

Lord Rayleigh, in introducing the deputation, said that Lord Crawford would have been present, but was detained at the London Electric Works at Deptford receiving a large number of American engineers interested in electricity. Lord Crawford had, however, written a letter dealing with the points that he would have touched upon. Lord Rayleigh then read a letter from Lord Crawford stating that had he been present he would have "drawn attention mainly to the requirements of undertakers as affected by the clauses of the provisional orders, and to show that obligations are put upon them to supply all descriptions of instruments for measuring quantity or pressure of an electric current. . . Every consumer has a right to claim a meter which must be a certified meter. . . . There are presently existing good and reliable forms of this instrument, but, owing to the want of reliable standards, instruments are often found to vary as much as 8 to 10 per cent." The letter further stated that "the Department should without delay inaugurate a laboratory, where we may send in our instruments to be passed in a manner similar to the procedure in the Weights and Measures Act. I think there is but little doubt that such an establishment would very shortly pay its way, and would not be a burden on Her Majesty's Treasury. . . . . A small fee for certificates would suffice to pay the expenses of such a laboratory, as, in addition to large numbers of new instruments, every time that an old one is interfered with for cleaning, etc., it will have again to be certified." Lord Rayleigh urged that the time had arrived when there was a certainty of an electrical supply on a large scale. That supply could not be afforded in accordance with the terms of existing legislation without the use of certified instruments, and at the present time there was no means of getting such certification. By the Act of last session electrical engineers were to issue certified standards, but there was at present no means of obeying the law.

Sir William Thomson then read the joint memorial of the London Chamber of Commerce and the Institution of Electrical Engineers, as follows:

"1. That it is impossible that the supply of electrical energy under statutory powers can be efficiently carried out without the provision of some means of standardising the meters and other instruments used in connection with such supply. 2. That the Board of Trade has recognised the necessity for this by inserting in licenses and provisional orders clauses requiring that these meters, etc., shall be of a pattern approved by the Board of Trade and certified as correct by a properly appointed inspector. 3. That the ordinary trade in electrical machines and instruments is much hampered and rendered uncertain by the want of generally recognised standards of electrical quantities. 4. That the required standards should be maintained by the Board of Trade as the department of Government entrusted with the administration of the Electric Lighting Acts, and as the warden of the standards of quantities used in other trades. 5. That, being strongly impressed with the absolute necessity for the establishment of a standardising laboratory where measurements of the various electrical quantities could be effected with the requisite precision, and whence certificates could be issued which would be accepted generally, the Electrical Section of the London Chamber of Commerce approached the Council of the Institution of Electrical Engineers on the subject. 6. That in consequence a joint committee of the two bodies was appointed to consider the matter, and that this committee has arrived at the following conclusions: (*a*) That the absolute value of the accepted units of the various electrical quantities has now been determined with such accuracy that the possible error cannot exceed 1-400th, or one quarter per cent. The most recent determinations may therefore be taken for practical purposes as correct, and no future corrections vitiating previous certificates need be apprehended. (*b*) That instruments and methods are now available by means of which the constancy and accuracy of measurement of electrical units and multiples of these units in a properly-equipped laboratory, and under proper supervision, can be assured. (*c*) That the cost of establishment of such a laboratory exclusive of building on the smallest scale suitable for the present requirements of the trade will not exceed the sum of £4,000. (*d*) That the joint committee aforesaid has devoted much time and consideration to the question, and the estimate at which they have arrived is as close as it was possible to make. (*e*) That they further are of opinion that by charging moderate fees for comparisons and certificates the Board of Trade would be in a position to remit the Treasury interest on this outlay, and also to provide a fund for maintenance and possible extension of the laboratory. 7. That we have now the honour to bring the above-mentioned facts to your notice, and pray that they may receive the serious consideration of the Board of Trade."

From a scientific point of view the possibility of electrical measurement had become demonstrated within the last few years very much through the labours of Lord Rayleigh, who had given them a correct determination of the standard of resistance. Unless they had instruments to test with accuracy, it would be impossible to work out the Electric Lighting Act.

Sir Vincent Barrington, on behalf of the council of the London Chamber of Commerce, said that they had unanimously determined to support this movement.

Mr. Crompton said those engaged in the work of electricity were placed at a considerable disadvantage with foreigners, who had the advantage of making the whole of their instruments and sending them for certification to Berlin and Paris, where standardising laboratories had been established by their respective Governments. When instruments were thus certified, they had a higher commercial value in the markets of the world than our instruments that had no such certification.

Sir Michael Hicks-Beach, in reply, said they had been speaking on a subject of a highly technical character with which he could not pretend to be specially conversant. He thought in principle there were very good grounds indeed for their request, and more than that he could not say at present, but he would look very carefully into it. He should, of course, have to bring the subject, if he felt able to do so, before that rather difficult department, the Treasury. He thought that they had put before him very good grounds for some such provision being made as they had requested.

Lord Rayleigh having thanked the right hon. gentleman, the deputation withdrew.

COST OF MAINTENANCE.

The following figures are given as to the cost of the electric light at the Moliere Mines. A Brush dynamo lights 16 arcs, of 75 carcels, and gives at 1,000 revs. 839 volts at 9 amperes. The cost of the installation was 20,389f.—thus:

Engine and Gearing	5,400f.
Brush dynamo	6,000
Lamps	3,840
Cables	1,380
Installing	3,769
	20,389

The installation has been working since 1884, as the following will show:

Year.	Total Cost.	Hours Light Used.	Per Hour Cost.	Per Lamp Hour.
1884	1,728·85f.	370	4·67	0·28
1885	3,149·95	669	4·70	0·28
1886	2,126·90	608	3·49	0·20
1887	1,985·40	507	3·91	0·23
1888	1,311·55	440	2·98	0·18
	10,302·65	2,594	3·95	0·23

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence ; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

The index of the current volume will be given with our next number, and every purchaser should receive it free of cost.

We commence our report of the Paris Exhibition with a general article on the exhibits in this issue, and the descriptions of special exhibits will appear from time to time till the whole have been described.

Specimen copies of the paper will be sent on request.

THE PARIS ELECTRICAL CONGRESS.

If the French do not initiate much except exhibitions and congresses, they always manage to obtain a good deal of the world's attention in some way or other. Above all things, they are great on congresses. Some sixty-five have been arranged to be held during this year's Exhibition, and no doubt each one will satisfactorily settle some question or other. However, to the phlegmatic Dutch or Englishman the congresses resolve themselves into paying *vingt francs*, and getting nothing for it. A certain number of ardent spirits are always ready to provide the "francs," and to believe the talkee-talkee that goes on in the meetings is really good and valuable work. To those who have only "vingt francs" for congress or theatre, we say take the latter. We have before us a programme of the Electrical Congress, and our investigation of the programme—or our ignorance of a foreign tongue—leads to the conclusion that it has no "objective."

The Congress of 1881 always seemed to us a mistake, and it is now paraded before us as an epoch marking date when practical units were determined. The ten years' agreement which then took place has had no effect at all, either in the workshop or in the laboratory, nor would an agreement come to-morrow by a score or two of congressists to call the "yard" or "foot" by some other name, have any effect in assisting to better construct a dynamo, railway line, or Forth Bridge. This programme tells us that 1889 offers a natural occasion to complete the work of 1881. Small boys who have flower gardens are often seen pulling up their plants to see how the roots are getting on; they do not understand that the plants thrive best by being left alone. And this is the case with some people with "measures and units"; they want to be everlastingly tinkering and changing in order to get an "ideal" system. Orthodox and heterodox. The former are those who bow down and worship the dozen change-ringers, the latter are all the other nobodies. We prefer something settled and the nobodies. Was it not a Quaker who, acting on the defensive, pushed back an aggressor with "Thee is not wanted here"? Uncle Tom can tell, but with regard to measures and units we say, Let us have peace.

It is quite time a stand was made against the actions of those who have no object in life but to propose, agitate, and change, and we shall be prepared to view with disfavour any attempt to impose any alteration in our practical units. If the framers of this programme had contented themselves with discussing certain interesting practical questions, obtaining thereon a consensus of practical opinion, we could have supported it without a word of adverse criticism. The practical man does not at the present time require a lot of scientific finesse upon questions of minutiæ, but he wants to know

Digitized by Google

how his colleagues in various parts have overcome the practical difficulties that arise in constructional and installation work. He does not care a fig whether the ohm be 102·3 or 102·34 mm. of Hg with a given sectional area, but he does want to know if any colleague has left the trammels of "percha," "rubber" and Co., and gone into something new for insulation of high pressure. Like the gas manager, too, he wants to know how best to keep down leakage. He knows something of what can be done with the A. T. distributing system, also with the B. T. system, but the experience is comparatively limited, and with comparatively small installations, so he wishes to collect all the information he can. Then patentees and promoters tell us on paper that this method of traction is cheaper, and that this or that apparatus is economical. The manufacturer and the user both want actual figures, not hypothetical ones. A congress that would bring out information on these and on a hundred similar questions would indeed be valuable. Pile up your experiences, not your theories. Let history slide in the face of present practice. Time moves too quickly to trouble about what was done in 1881 or 1886. What is being done in 1889? is the question. The answer would enable us to avoid the errors of 1881 and of 1886, though those of 1889 will exist, and only the future will teach how to avoid them. If our suggestion could be carried out, nothing should be said at the congress except to describe apparatus in actual work—its successes and its failings—and apparatus installed since, say, January 1st, 1888. Apparatus untried should be as rigidly tabooed as references to the stone or bronze age.

The programme shows the work of the eight days from August 24th to be divided among six sections dealing respectively with (1) Measures; (2) Dynamos, Transformers, Distribution; (3) Electro-Chemistry; (4) Lighting; (5) Telegraphy with sub-sections Telegraphy, Telephony, and Various Applications; (6) Electro-Physiology. Now, in the first place, who are the men going to provide the papers to be discussed? Are they of the workshop, or are they of the study? The promotors of the feast should give some idea of what they will provide to enable the would-be guest to see if value for "vingt francs" is to be given. If we remember rightly, in 1881 the congress was followed by the establishment of an International Electrical Society. What has that society done? Does it still exist? and have the members been quite satisfied with its working? We are quite willing to assist society, congress, or exhibition that appears likely to do some good, but these mutual admiration congresses, got up for the glorification of the few at the expense of the many, leading to no general benefit, are to be condemned.

There seems to exist amongst the dilettanti an hereditary inability to see the problems of the day, and complete failure to grasp that which is important and that which is unimportant. The motto of the Royal Agricultural Society might be well kept in view—"Experience with Practice."

MAGNETISM IN ITS RELATION TO INDUCED ELECTROMOTIVE FORCE AND CURRENT.*

BY ELIHU THOMSON.

There is perhaps no subject which at the present time can have a greater interest to the physicist, the electrician, and the electrical engineer than the one which heads this paper. The advances which have been made in the study from its purely theoretical or scientific side, and the great technical progress in the utilisation of the known facts and principles concerning magnetic inductions, can but deepen and strengthen that interest.

On the side of pure theory we find the eager collection of experimental data to be submitted to the scrutiny of the ablest and brightest minds, to be examined and reasoned upon with the hope of finding some clue to satisfying explanations, and, on the side of practice, we find the search for new facts and relations no less diligent, though often stimulated by practical problems presented for solution. Indeed, the urgency for results is often the greater on the practical side, for theory can wait, practice cannot, at least in the United States.

We must look for continued triumphs in both directions, and the most welcome of all will be the framing of a theory or explanation which will enable us to interpret magnetic and electric phenomena. The recent beautiful experiments of Hertz on magnet waves have opened a fertile region for investigation.

It would seem that the study of magnetism and electricity will give us the ability to investigate the ether of space, which medium has been theorised upon at great length, with the result of leaving it very much where it was before—a mysterious necessity. Faraday says, speaking of magnetism: "Such an action may be a function of the ether, for it is not at all unlikely that if there be an ether it should have other uses than simply the conveyance of radiations." 3,075. Vol. iii., Exp. Res.

"It may be a vibration of the hypothetical ether, or a state of tension of that ether equivalent to either a dynamic or a static condition, etc." 3,263. Vol. iii., Exp. Res.

Faraday again says, speaking of the magnetic power of a vacuum: "What that surrounding magnetic medium deprived of all material substance may be I cannot tell, perhaps the ether." 3,277. Vol. iii., Exp. Res.

Modern views would seem to point that through a study of magnetic phenomena we may take a feeble hold upon the universal ether. Magnetism is an action or condition of that medium, and it may be that electrical actions are the expression of molecular disturbances brought about by ether strains or interferences. The close relations which are shown to exist between magnetism and light tend to strengthen such views. Indeed, it would not be too much to expect that if the mechanics of the ether are ever worked out we should find the relation between sensible heat and electric currents to be as close as that of light to magnetism, perhaps find ultimately the forms of matter, the elements and compounds to be the more complex manifestations of the universal medium; aggregations in stable equilibrium. It is a difficult conception, I confess, and a most shadowy and imperfect one, yet facts and inferences which favour such views are not wanting.

Our science of electricity seems almost to be in the same condition that chemistry was before the work of Lavoisier had shed its light on chemical theory. Our store of facts is daily increasing, and apparently disconnected phenomena are being brought into harmonious relation. Perhaps the edifice of complete theory will not be more than begun in our time, perhaps the building process will be a very gradual one, but I cannot refrain from the conviction

* Paper read before the American Institute of Electrical Engineers, New York, May 22, 1889.

Digitized by Google

that the intelligence of man will, if it has time, continue its advance until such a structure exists.

I have been led to make these general allusions to electrical theory in order to emphasise the fact that in the present paper no unravelling of the mystery is to be attempted, but rather the presentation of some few considerations upon a subject of absorbing interest.

The conception of Faraday in regard to the existence of lines of magnetic force representing directions of magnetic strain or tension in a medium has not only lost nothing of its usefulness up to the present time, but has continually been of great service in the understanding of magnetic phenomena. We need spend no time in showing, as Faraday and others have done, that these lines are always closed circuits, polarised so that the direction of the lines cannot be reversed without reversal of the actions. Nor need we take time to show that in any medium the lines are mutually repellant laterally if of the same direction of polarisation. Opposing this tendency to separation or lateral diffusion of magnetic force is the strong apparent tendency of the lines to shorten themselves in any medium. These actions are disturbed by the presentation of a better medium, as iron instead of space or air. Lines of force will move into the better medium, having apparently the constant tendency to diminish the resistance in their paths.

The peculiar and mysterious nature of media such as iron is to permit an extraordinary crowding of lines on account of slight resistance to their passage through it. We need not, in addition, do more than refer to the other well-known facts of an electric current developing magnetic lines encircling the conductor, as being the general type, which includes all forms of magnetic field, or electro-magnets, sustained by currents, and the fact of a development when magnetic lines or circuits and material masses are in relative movement of E.M.F.'s transversely to the direction of the lines of magnetism and also transversely to the direction of relative movement, as in the case of electric conductors traversing or cutting through a field, or a field traversing or being moved across a conductor. We must not forget that even insulators, as well as conductors, cutting lines of force, have the E.M.F. developed in them. The action simply develops potential difference, and this generates the current where a circuit exists. While we are in the habit of saying that a conductor moved across a field of lines, or *vice versa*, generates electric current, I think the statement incomplete. The movement only sets up a potential difference and the power expended in effecting the movement generates C × E. The current is energy less the potential, or the energy expended gives the two effects of potential or pressure, and current or rate of movement. Consequently, an insulator, or an open-circuited conductor, traversing a field, consumes no energy, potential difference only being produced. Nevertheless, as will be shown, the magnetic circuits or lines themselves may furnish the energy for their own movement across a conductor, and so develop current as well as potential. This occurs in the effort of lines to shorten their paths, to lessen their density, to pass to better media. Indeed, a close examination will show that wherever power is expended in developing current in a circuit, cutting lines of force, the energy expended is first employed in stretching the lines, which thus receive the energy required to permit them, in shortening, to cut the conductor and set up currents in the electric circuit in accordance with the potential difference developed in that circuit and its resistance.

I think, we may also say, though I do not remember to have seen the statement so put, that whenever electric potential is set up inductively, as in self-induction, mutual induction, induction from one circuit to another and induction from magnets or magnetic field, it is set up by the movement of lines of force laterally across the body, mass, or conductor in which the potential is developed, and that whenever current is set up in a wire or an existing current prolonged, or an existing current checked by induction, self-induction or induction from magnets, the action is a transfer of energy, represented by strained lines of force shortening or lessening their resistance, or lengthening and increasing the resistance in their paths. The magnetic field is like an elastic spring: it can in one condition represent stored energy—it can be strained and will store energy—it can be made to relieve its strain and impart energy.

Let us examine some known phenomena in this light. Take the case of a simple wire, conveying current, say, in a line away from the observer, Fig. 1. There exists a free field of circular magnetism (so-called), shading off away from the wire, and which is represented by concentric circles of increased diameter. The superior intensity or strength of the lines near the wire may also be represented by their thickness. This is often shown also by crowding the lines near the wire, though I am disposed to regard Fig. 1 as more nearly expressing the condition, unless we are to regard the lines as simply indicating a sort of atmosphere of magnetic effect whose density becomes less as we proceed outward from the wire, in which case either form of symbol suffices. The direction of polarisation of the lines may be indicated by an arrow-head pointing in a direction of right-handed rotation in the path of the lines. This is, the typical figure or expression for all forms of simple magnetic circuit—the form of the lines, their length, position, density, will depend on the shape of the conductor or conductors (when more than one) and the materials surrounding or in proximity to the wire or wires.

If the current traversing the conductor is constant, the magnetic field around it is stable and static, unless other influences come in to modify it. The cutting off of the current is followed by instability of the field whereby it can and must produce dynamic effects. I say *must* because the field represents stored energy and in disappearing *must* give out that energy. To throw light on this part of the subject is one of the objects of the present paper. Cutting off the current supply in the case assumed leaves the developed magnetic lines or strains unsupported, they at once shorten their paths or circuits, collapsing upon the conductor, as it were, and, continuing this action, cut the section of the conductor, and apparently disappear in magnetic-closed circuits of infinitesimal diameter, but of great strength of polarisation. It appears to me that we must either be prepared to give up the idea of lines of force, or take the position that the magnetic circuits precipitate themselves in shortening their circuits, and disappearing upon and cut the conductor. It was Hughes who put forward the idea that an iron bar, in losing its apparent magnetism, really short-circuits the lines in itself as innumerable strongly-magnetised closed circuits among the molecules. In becoming magnetic once more, these short circuits are opened or extended into the air by some source of energy applied to strain the lines, such as a current in a conductor around the bar.

May not this idea be extended, then, to include the magnetic medium, the ether itself? Does it contain intensely polarised closed circuits of magnetism which are ready to be stretched or extended under certain conditions by the application of energy, which energy is returned by the collapse of the extended circuits? This is doubtless but a crude expression of the real condition of things, for the lines are only symbols for a condition of strain in a medium which cannot be represented in thought, as we know nothing of its real nature. There is one point in this connection which I must emphasise. The strained lines, Fig. 1, are indications of stored energy in the ether, and the lines *cannot* disappear without giving out that energy. Ordinarily, it makes it appearance as the extra current, and adds itself so as to prolong the current which extended the lines when an attempt is made to cut off such current. Were it conceivable that the current could be cut off and the wire put on open circuit while the lines still remained open or strained, the energy must still escape when the field disappears. It would then produce such a high potential as to be able to discharge from the ends of the conductor, and if the conductor were of some section, part of the energy would be expended in setting up local currents in it. The field could not disappear without an outlet for the energy it represents. But we cannot cut off a current in a wire so as to leave the wire on open circuit with the lines of the magnetic circuit remaining around it without iron or steel or the like in the magnetic circuit. We can approach that condition, however

Digitized by Google

by breaking the circuit very quickly with a condenser of limited capacity around the break. This is done in the Ruhmkorff coil primary. The condenser forms a sort of blind alley for the extra current on its beginning to flow out of the primary coil; but the condenser charges and backs up and stops the discharge from the primary, even giving a reverse current. The lines of magnetic force collapse, however, and have their effect in the enormous potential set up in the secondary coil.

Take away the secondary coil so as to stop that outlet, the energy expends itself on the iron core and the primary coil. Take away the iron core, and the energy of magnetisation of the air or ether core expends itself on the wire of the primary, and possibly, also, on the dielectric of the condenser to some extent. The extra current becomes in this instance an oscillatory discharge of very high period back and forth through the primary coil from the condenser, until the energy is lost in the heat of $C^2 \times R$. This conversion is doubtless rendered all the more rapid by uneven distribution of current and eddy current set up in the wire of the coil.

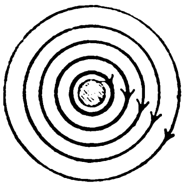

Fig. 1.

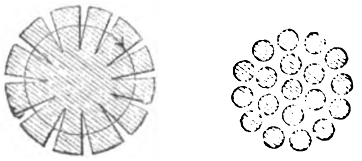

Fig. 3.

The considerations just given concern the loss of field or the shortening and apparent disappearance of the magnetic lines or circuits, as g'ving rise to the self-induction or increased potential on breaking. Where the energising current is slowly cut off or diminished the energy is gradually transferred to the wire in producing elevation of potential during the decrease; and the collapse and cutting of the wire by the collapsing circuits or lines is then only more gradual.

Let the current be returned to the wire after disappearance of magnetism, and the lines again seem to emanate from the wire and at the same time cut it and produce a counter potential in it, which is the index of the abstraction of energy from the circuit, and its storing up in the form of elastically strained lines of magnetism around the conductor. The effect is that of self-induction on making or upon increase of current, the measure of the amount being the

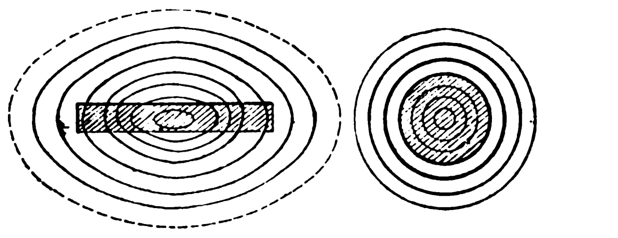

Fig. 2.

energy stored in the magnetic circuits which have been extended or opened up by the current. The greater the current and the shorter the path for the lines developed around the axis of the conductor, the greater the energy stored up. Hence, a circular section conductor has the highest self-induction, a tube of same section less as its diameter increases, a flat strip has less as its width increases and thickness diminishes, a divided conductor much less than a single conductor of same shape and section. Separating the strands of a divided conductor increases the length of magnetic paths around it, and so diminishes the self-induction. A striking instance of this latter fact was developed in conveying very heavy alternating currents of very low potential a distance of about three feet by copper conductors, the current being used in electric welding operations.

The conductors were built up of flat thin strips of copper for flexibility. When the strips were allowed to lie closely together the short conductor showed an enormous self-induction, which cut down the effective potential at its ends near the work. By spreading apart the strips, so as to lengthen a line around the conductor, the self-induction could be easily made less than 35 per cent. of what it had been before. The interweaving of the outgoing and return conductor strands as one compound conductor gets rid almost entirely of the self-inductive effects, because neither conductor has any free space in which to develop strong magnetic forces, but is opposed in effect everywhere by the opposite current in its neighbour.

Where a number of conductors are parallel and have the same direction of current, as in a coil or in a strand, it is evident that statically the conductor may be considered as replaceable by a single conductor with the same external dimensions and same total current in the area occupied, the magnetic forces or lines surrounding them being of same intensity. But with changing current strength the distribution of current in the conductor has also a powerful effect on the energy absorbed or given out in accordance with the magnetism produced. Hence the self-induction of a strand, coil, or conductor of the same section varies with the rapidity of current changes, owing to the conduction eing uneven.

The uneven distribution of current, or its tendency to

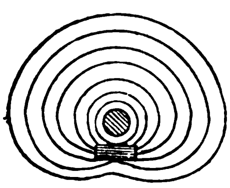

Fig. 4. a

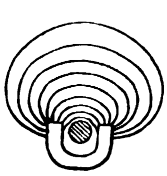

Fig. 4. b

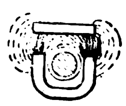

Fig. 4. c

flow on the outer parts of a conductor when the rate of variation or alternation is made great, is in itself a consequence of the fact that less energy is transferred into magnetism in this case, that when the current flows uniformly over the section or is concentrated at the centre. In other words, when a uniform current traverses a conductor of the same section the circular magnetism or surrounding magnetic lines are to be found not only outside the conductor, but also beneath its exterior. Since in forming these lines on passage of current the middle of section would be surrounded by more lines than any other

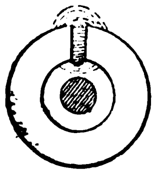

Fig. 5.

Fig. 6.

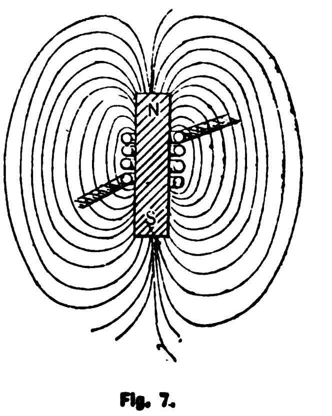

Fig. 7.

part of the conductor, the current tends to keep out of that part and move near the exterior in greater amount. Hence, in rapidly-alternating currents, the conductor section is practically lessened, being restricted largely to the outer metal of the conductor. If the round conductor, Fig. 2, were made of iron, the magnetism interior to it, and set up by a current in it, would be very much greater, the section of the conductor being filled with magnetic circuits or lines around the centre. The total magnetism, external and internal, would be much greater in this case for a given current flow, and the energy absorbed and given out in formation and loss of field, or the self-induction, would be much increased. This could, however, be greatly diminished by slitting the conductor radially, or making it of a number of separate wires out of lateral magnetic contact, one with the other, Fig. 3. In these cases the resistance of the interior magnetic circuits would be increased, as there would be several breaks in the continuity around the centre of the conductor. The total magnetism which could be set up by a current would be lessened, and the self-induction therefore, lessened.

The moment we begin the bringing of iron into proximity with an electric conductor conveying current, we provide a better medium for the flow or development of magnetic lines or circuits. In other words, the lines may then be longer, yet equally intense, or more lines may be crowded into a given section of this metal than in air or space. Figs. 4*a*, 4*b*, 4*c* show the effect brought about by bringing iron of different forms near to the conductor.

It shows, in other words, the development of the ordinary electromagnet of the horseshoe form, and the concentration of the lines in the better medium. The lines also tend to shorten and diminish the resistance to their passage, so that attraction of the iron to the conductor takes place, and if there is more than one piece of iron they tend to string themselves around the conductor in magnetic contact with one another.

When copper bars of 1in. diameter are traversed by currents of 40,000 to 60,000 amperes, as in welding them, the magnetic forces just referred to become so enormous that very heavy masses of iron brought up to the bar are firmly held, even though the current be of an alternating character, changing direction many times a second.

When a conductor is surrounded by a cast-iron ring, as in Fig. 5, the current in such conductor has an excellent magnetic medium surrounding it. A large amount of energy is then abstracted on the first impulse of current, which goes to develop strong and dense magnetic lines through the iron ring and across the gap in it. On taking off the current the energy is returned as extra current, and its force is many times what would be found with air alone surrounding the conductor. We have then greatly increased the self-induction, the storing of energy and opposition to current flow at the beginning, the giving back of energy and assistance to the current flow on attempting to remove or stop the current. Let us now complete the ring by making it of iron, endless, Fig. 6, with the conductor in the middle.

We now find that on passing current through the conductor it meets with a very strong opposing effect or counter potential. The evolution of magnetic lines or the opening out of magnetic circuits goes on at a very rapid rate. Each line or magnetic circuit evolved and cutting the conductor, flies at once outward and locates itself in the iron ring. This ring can carry innumerable lines, and they do not crowd one another. It permits the lines even to lengthen in reaching it, and yet, on account of its low resistance to their passage, the lengthening is equivalent to their having shortened in other media. We will suppose the current not sufficient to exhaust this peculiar capacity for lines which the iron has. Equilibrium is reached, the conductor has opened up innumerable closed circuits and caused them to exist in the ring still closed, but in iron, not space or ether merely. The current passing has continued its action and storage of energy until, to emit another line in view of the resistance now found in the crowded iron ring, is impossible.

Now, let us cut off the current. We are surprised to find a very weak extra current, a practical absence of self-induction on breaking, or at least a giving out of energy in no wise comparable to that on making. Let us put on the current as it was before. Another curious result. But little self-induction now on making, energy not absorbed.

Now cut off the current again. Same effect as before. Now let us put on the current reversed in direction. At once we find a very strong counter potential or opposing self-induction developed.

The ring had been polarised, or retained its magnetic energy, and we are now taking out one set of lines and putting in reversely polarised lines of force. This done, we break the reversed current without much effect of self-induction. The ring remains polarised and inert until an opposite flow of current be sent through. Iron is then a different medium from the ether.

The ring once magnetised must in losing its magnetism permit a closure of the lines by shortening. This involves their passage from the iron across the space in the centre of the ring, notwithstanding its great resistance to the lines of force. As passage from iron to air is equivalent to lengthening of the lines it is readily seen that such lengthening may oppose more effect than a slight shortening due to leaving iron, for air or space may give in provoking a closure and disappearance of the lines. Looked at from another standpoint, the lines on the iron may actually require a small amount of initial energy to dislodge them therefrom, so that after being dislodged they may collapse and yield whatever energy they represent.

I must reserve for the future further consideration of the iron ring, but in thinking upon this matter I am led to think that the production of a magnetic line in an iron ring around a conductor may represent a sort of wave of energy, an absorption of energy on the evolution of the line from the conductor, and a slight giving out of energy on the line reaching that position of proximity to the iron ring that its passage thereto may said to be a shortening process or a lessening of its resistance.

The magnetism in air, gases and non-magnetic bodies, being assumed to be that of the ether, this medium shows no such effects as those we get with the ring. It does not become permanently polarised, as does even soft iron under the condition of a closed ring. The iron possesses coercive force, or magnetic rigidity, and a steel ring would show more of it. The molecules of the iron or steel take a set. If we were to cut the soft iron ring, or separate it in any way, this introduction of resistance of air for ether in the magnetic circuit would cause the lines to collapse, and set up a current in the conductor. The energy of the ring would have been restored to the latter. The curious thing is that physically the polarised ring does not present any different appearance or ordinary properties different from those of a plain ring, and will not deflect a compass needle Its condition is discoverable, however, by the test of self-induction to currents of different direction. As a practical consideration, we may mention in this connection that a self-inductive coil for currents of one direction must be constructed differently from one to be used with alternating currents. The former must have in its magnetic circuit a section of air or the like, or be an imperfectly-closed circuit, as it were. The latter should have as perfectly-closed a magnetic circuit as can be made. We see here, also, the futility of constructing a Ruhmkorff core coil on the closed iron magnetic circuit plan, because the currents in the primary are interrupted, not reversed.

The considerations just put forward in relation to the closed iron ring, and its passive character under the condition of becoming polarised, are more important than at first appears. It has been found that the secondary current wave of a closed iron circuit induction-coil or transformer, whose primary circuit receives alternating current, is lagged from its theoretical position of 90deg. behind the primary wave an additional 90deg., so that the phases of the two currents are directly opposed; or the secondary current, working lamps only in its circuit, is one half a wave length behind the primary, instead of only a quarter wave length, as might have been expected.

But when it is understood that the iron core polarised in one direction by the primary impulse does not begin to lose its magnetism when that impulse simply weakens, but waits until an actual reversal of current has taken place, it will be seen that the secondary current, which can only be produced when magnetic lines are leaving the core and cutting the secondary coil, or when the lines are being evolved and passing into the core from the primary coil, will have a beginning at the moment the primary reverses, will continue during the flow of that impulse, and will end at substantially the same time with the primary impulse, provided the work of the secondary current is not expended in overcoming self-induction, which would introduce a further lag. Moreover, the direction of the secondary current will be opposite to that of the primary, because the magnetic circuits which are opened up by the primary current in magnetising the core, or which are closed or collapsed by it in demagnetising the core, will always cut the secondary coil in the direction proper for this result. Transformers of the straight core type with very soft iron in the cores and not too high rates of alternation should approximate more nearly the theoretical relation of primary and secondary waves, because the magnetic changes in the core are capable of taking place almost simultaneously with the changes of strength of the primary current. This fact has other important practical and theoretical bearings.

Let us assume a plain iron core, Fig. 7, magnetised as indicated, so that its poles N S complete their magnetic circuits by what is called free field or lines in space around it. Let a coil of wire be wound thereon as indicated. Now assume that the magnetism is to be lost or cease, either suddenly or slowly. An electric potential will be set up in the coil, and if it has a circuit, work or energy will be produced or given out in that circuit, and in any other inductively related to it. Hence the magnetic field represents work or potential energy. But to develop potential in the wire the lines must cut the wire. This they can do by collapsing or closing on themselves. The bar seems, therefore, to lose its magnetism by gaining it all, and in doing so all the external lines of force moving inward cut the wire. The magnetic circuits shorten and short-circuit themselves in the bar, perhaps as innumerable molecular magnetic circuits interior to the iron medium. To remagnetise the bar, we may pass an electric current through the coil. The small closed circuits are again distended, the free field appears, and the lines moving outward cut across the wire coil opposite to the former direction, and produce a counter potential in the wire, and consequent absorption of the energy represented in the free field produced. As before studied, the magnetism cannot disappear without giving out the energy it represents, even though the wire coil be an open circuit, and therefore unable to discharge that energy. The coil open circuited is static, not dynamic. In such assumed case the lines in closing cut the core and heat it. Let us, however, laminate the core or subdivide it as far as possible, and we appear to have cut off this escape for the energy. This is not really so, however. We have simply increased the possible rate of speed of closure, or movement of the lines, and so have increased for the divided core the intensity of the actions of magnetic friction and local currents in the core, the latter still receiving the energy of the magnetic circuit. This reasoning is based on the possibility in this case of cutting off the current in the magnetising coil and retaining the magnetic field. This is of itself probably impossible with soft iron. That the core receives the energy when the coil cannot is shown in the well-known fact that in some dynamos with armatures of bobbins on iron cores the running of the armature-coils on open circuit gives rise to dangerous heating of the cores, and that under normal work the heating is less. In the former case the core accumulates the energy represented in the magnetic changes. In the latter, the external circuit of the machine and its wire coils take the larger part of the energy which is expended in doing the work in the circuit. In this case, also, the current in the coils causes a retardation of the speed of change and extent of change of magnetism in the iron cores, which keeps down the intensity of the magnetic reaction. In fact, this retardation or lag and reduction of range of magnetic change may in some machines be made so great by closing the circuit of the armature-coils themselves, or short-circuiting them that the total heat developed in the cores is much less than under normal load.

I wish now, in closing, to refer briefly to phenomena of moving lines of force, and to the effects of speed of movement. In order to generate a given potential in a length of conductor we have choice of certain conditions. We can vary the strength of field and we can vary the velocity. We can use a strong field and slow movement of conductor, or we can use a weak field and rapid movement of the conductor. But we find also that where the conductor has large section it is liable to heat from eddy currents caused by one part of its section being in a stronger field than another at the same time. One part cuts the lines where they are dense and the other where they are not dense, with the result of difference of potential and local currents which waste energy in heat. We cannot make the conductor move in a field of uniform density, because it must pass into and out of the field. The conditions just stated are present in dynamos for heavy current work, where the speed of cutting of lines is low and the armature-conductor large in section.

But we find that in a transformer secondary we can use very large section of conductor, even (as in welding machines) 12 to 15 square inches solid copper, without appreciable difficulty from eddy currents in it. The magnetic lines certainly cut the heavy conductor and generate the heavy current and potential needed. What difference, if any exists? In the transformer the currents are generated by magnetic field of very low density, in which the lines are moving across the conductor with extreme rapidity. The velocity of emanation of lines around the primary coil is probably near that of light, and each line passes across the section secondary conductor in a practically inappreciable time. There is no cause, then, for differences of potential at different parts of the section heavy secondary. Then, to avoid eddy currents in large conductors, and generate useful currents in them, we may cause the conductor to be either moved into and out of a low density field with very great speed, or better, we must cause the lines of a very low or diffused field to traverse or cut across the conductor with very high velocity.

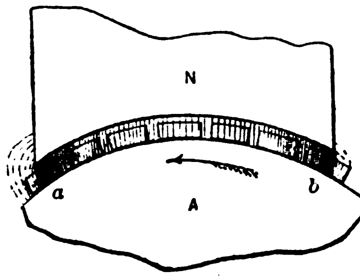

Fig. 8.

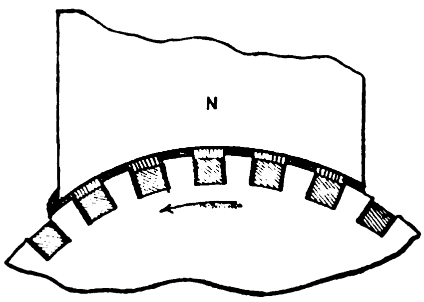

Fig. 9.

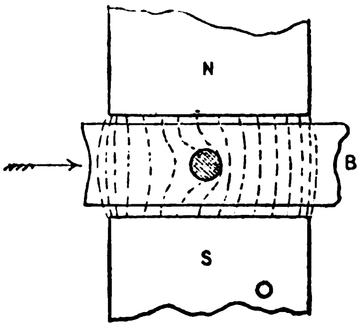

Fig. 10.

It is a known fact that in dynamos with large section armature-conductors there are less eddy currents produced in the conductors when they are provided with iron cores or wound upon iron cores, than when the conductors are made into flat bobbins moved in front of field-poles. Projections existing on the armature between which the conductors are placed have a like effect, and enable us to employ heavy bars or bundles of wire without much difficulty from local currents. The reason is simple. In the armatures with coils without iron in them or without projections extending between the turns the conductor moves into and out of a very dense field at comparatively low velocity, so that any differences of potential developed in the parts of the section of conductor have full effect and abundant time to act in setting up harmful local currents. In the cases in which iron projects through the coil or conductor the real action is that the lines of the magnetic circuits move at high speeds across the conductor, and the conductor is at all times in a field of very low density. Figs. 8 and 9 will make this plain. In Fig. 8 we have shown a smooth armature surface having a heavy conductor laid thereon, and which is at *a*, just entering a dense field at the edge of the pole N and at *b* leaving such field. It will be seen that when in such position the conductor, if wide, is subjected to varying field strength, and moves at a low speed for the generation of the working potential as it passes through the field, thus giving rise to eddy currents in the conductor.

In Fig. 9 the conductors are set down between projections, in which case both armature and field-poles are laminated or subdivided. As each projection leaves the edge of field-pole N, the lines which it had concentrated on and through it snap backward at an enormous speed and cross the gap to the next succeeding projection on the

Digitized by Google

armature, cutting the whole section of the heavy armature-conductor at practically the same instant. This brisk transfer of lines goes on from each projection to the succeeding one in front of the field-pole, leaving a very low density of field at any time between the projections. The best results would be obtained when the armature-conductor does not project beyond or quite fill the depth of groove between the projections. Of course there are other remedies for the eddy current difficulty, notably the stranding and twisting of the conductor on the armature so as to average the position of the parts of the compound conductor.

Perhaps the most extreme case of what may be called dilution of field by projections and by closed magnetic circuits in transformers would be that of a block of iron, B, Fig. 10, moved between poles N and S, and having a hole through it, into and through which a conductor is carried. The path through the iron is so good that we can scarcely consider that any lines cross the hole from N to S, yet as B moves forward there is a continual snapping transfer of lines from the right forward side of the hole to the left or backward side, cutting the conductor as they fly across, and developing an E.M.F. in it. I have described this action more in detail because we have it in whatever distinction in the manner of cutting the lines of the field is to be found between wire on smooth armatures and on projection armatures and modifications thereof; and also between flat, open coils passing through a field and bobbins with cores of iron. The considerations advanced also bring out the relation which exists between closed iron circuit transformers and closed iron circuit (projection) dynamos, as we may call them.

I had intended at the outset of this paper to deal to some extent with the propagation of lines of magnetism undergoing retardation in reference to alternating-current motor devices, transformers with limited secondary current, or constant average current, an alternating motor working with what I may term a translation lag, etc.; but it was soon found that these matters must remain over for a continuation of this paper at some future time. My endeavour has been in the present paper to deal with the lines of force theory as though it were a symbol of the reality; but I confess that it is done with many misgivings that I may have carried it too far. Yet, if we are to use the idea at all, it has seemed but right to apply it wherever it may throw any light on the subject or assist in our understanding of phenomena.

ELECTRIC MOTOR REGULATION.*

BY FRANCIS B. CROCKER.

Although this subject is one of great scientific and practical interest, it has not been very frequently or very fully treated up to the present time. Of course, motor regulation is very similar to dynamo regulation, but it is by no means identical with it, and it deserves and requires separate treatment. I do not think it is much exaggeration to say that at the present time there is no subject more generally important to electrical engineers than motor regulation. Considering this fact, it is certainly remarkable that the literature of the subject is so limited. We find stray articles in electrical periodicals, rarely more than a description of one particular invention, and in electrical books, regulation is referred to incidentally in connection with descriptions of the various motors. There is also, to be sure, usually one short chapter devoted to this subject, but it is apt to be either very general, merely mentioning a few regulating devices, or else it is confined to the mathematical analysis of some one particular method.

Motor regulation is a subject which is somewhat confusing, and requires therefore accurate definition of the quantities and conditions which enter into it. One case is, at first sight, very similar to another, and yet, more careful consideration will show, very likely, that it is exactly opposite. Take, for example, the two commonest and most important cases—viz., the constant-potential and the constant-current motors. The conditions of the two cases are precisely opposite, and the solution of the problem is, naturally, entirely different. To maintain a motor at a constant speed with a variable load, on a constant-potential circuit, which is the case of the ordinary shunt motor on the regular 110-volt incandescent circuit, is a very easy problem—in fact, it solves itself. A simple shunt-wound motor will run at a practically constant speed on a constant potential circuit, even if the load varies from zero up to the full capacity of the motor. Now this form of motor is exactly what we would use, even if we did not care to have it regulate. It is customary, to be sure, where very close regulation is required, to wind constant-potential motors differentially—*i.e.*, with series as well as shunt-coils—but this is not essential for ordinary work.

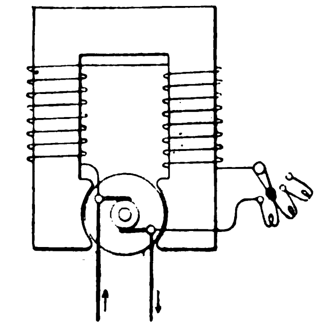

Fig. 1.—Shunt Motor with variable resistance in field circuit.

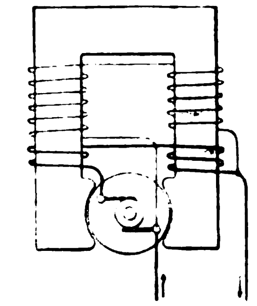

Fig. 2.—Differential motor. Self-regulating.

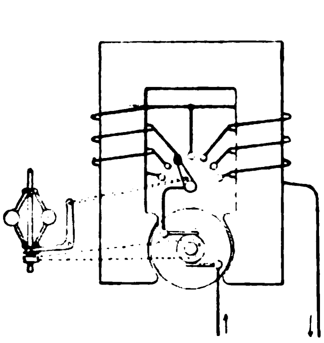

Fig. 3.—Series Motor with switch for cutting out coils in series.

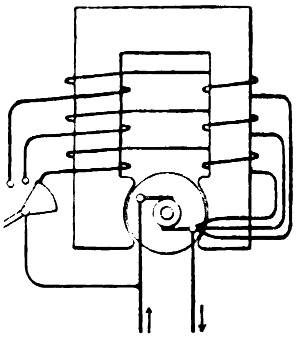

Fig. 4.—Shunt Motor with switch for cutting out field coils in multiple arc.

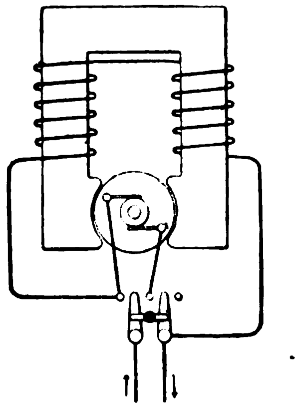

Fig. 5.—Motor with switch for throwing armature and field in series or in multiple arc.

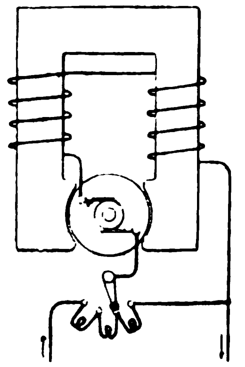

Fig. 6.—Series Motor on variable shunt.

The case of the constant-current motor, on the other hand, is as difficult as the first is easy. It seems as if it had to bear the burden of both. Neither a shunt-wound nor a series-wound, nor a compound-wound motor can be used practically on a constant-current circuit to maintain a constant speed with variable load. The ordinary series-wound motor, which is the natural and common form for the constant-current motor, will race away when the load is taken off and increase in speed until it tears apart or strains the armature and ruins the machine. We require some special and very effective device to accomplish the regulation in this constant-current case, and it seems to happen that almost every device that has been thought of has serious difficulties and complications. The ordinary, and what would seem to be the best, solution of this

* Paper read before the American Institute of Electrical Engineers, New York, May 22, 1889.

Digitized by Google

problem is to vary the magnetic effect of the field upon the armature directly in proportion to variations in the load. This is effected by cutting out the field-coils, and by other methods which will be described later. But there are difficulties with almost all these plans.

These two cases, which, as already stated, are the commonest and most important which occur, and yet which are so very different in almost every respect, give a general idea of what we have to deal with in motor regulation.

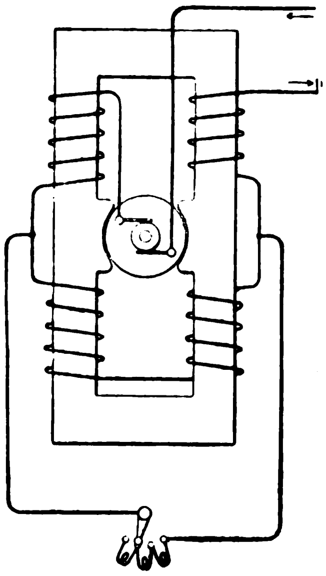

Fig. 7.—Series Motor with variable magnetic shunt.

20. Moving pole-pieces away from armature. Fig. 10.
21. Moving armature away from pole-pieces. Fig. 11.

Table II.—*List of Possible Cases with Direct Currents.*

P = Difference of potential in volts at terminals of motor.
C = Current in amperes supplied to motor.
S = Speed of armature in revolutions per minute.
L = Load or torque in pounds at 1ft. radius.

Any of these four quantities may be either constant or variable, making the following combinations :

Case.	Constant.	Variable.	Example.
1.	P	C S L	Series-wound motor with variable load on const. pot. cir.
2.	P S	C L	Shunt or comp.-wound motor with variable load on con. pot. cir.
3.	P L	C S	Shunt motor with con. load and var. field resist. on con. pot. cir.
4.	P S L	C	Not practical.
5.	P C	S L	Not likely to occur.
6.	P C S	L	Impossible.
7.	P C L	S	Impossible.
8.	P C S L		Shunt motor with constant load on constant potential circuit.
9.	C	P S L	Shunt motor with var. load on constant-current circuit.
10.	C S	P L	Series motor with speed gov. and var. load on constant-current circuit.
11.	C L	P S	Series on arc const. torque.
12.	C S L	P	Not practical.
13.	S	P C L	Motor with speed gov. and var. load on cir. of var. pot. and cur.
14.	S L	P C	Motor with const. load and speed gov. on. cir. of var. pot. and cur.
15.	L	P C S	Motor with con. load without speed gov. on cir. of var. pot. and cur.
16.		P C S L	Motor with var. load without speed gov. on cir. of var. pot. and cur.

In table I, motor regulation is divided into hand regulation, which, it happens, is almost always used for varying the speed of a motor, by a hand switch, Fig. 1, for example, and automatic regulation, which is almost always used to maintain a constant speed, and which is usually accomplished in one of the three following ways : First, by a centrifugal governor similar to that of the steam-engine, operating a switch or other device, Fig. 3 ; secondly, by a dynamometric governor—*i.e.*, a mechanism through which the load or torque of the motor is transmitted, which may also operate a switch and vary the power of the field by the direct effect of changes in the load ; thirdly, by an electromagnet device, such as a solenoid, through which the current, or a portion of it, is passed, which causes the core of the solenoid to move and operate a switch in accordance with variations in the current, Fig. 9.

The table next gives the principal methods used to regulate motors. These consist of different arrangements and combinations of parts to produce different effects or changes in the working of the motor, and they constitute the means which we have to employ to accomplish a certain object in motor regulation. Method 1 is simple shunt-winding, which consists in exciting the field-magnet with a circuit of comparatively high resistance in multiple arc with the armature (Fig. 1). This maintains a motor at constant speed with varying load on a constant-potential circuit, and does this all by itself, as it were, without any trouble, as already pointed out. The reason for this is that the field,

Digitized by Google

being fed with a constant potential, is therefore of constant strength, and a slight variation in speed of the armature, about 5 per cent., will vary the current in it from zero up to its full capacity, and therefore vary its power to an equal extent.

Method 2 is differential winding (Fig. 2), which is a refinement of the first, by which an almost absolutely constant speed—*i.e.*, within one or two per cent.—may be practically maintained. This consists in winding a series-coil of comparatively few turns upon the field-magnets, in addition to the shunt-winding in the previous case, the series-coil being wound in the opposite direction and opposed magnetically to the shunt-coil. The effect of this is to slightly weaken the field magnetism as the load on the armature, and consequently its current, increases. This tends to increase the speed of the armature and counteract its tendency to slow down with increased load, thereby almost entirely eliminating even the small variation of 5 per cent. in speed which occurs in the ordinary shunt-motor. The paradoxical fact that a shunt-motor increases its speed with the weakening of the field-magnet is well known, being due to the lowering of the counter E.M.F., and consequent increase of current in the armature as the field magnetism is reduced in intensity.

In the next three methods the external resistance in series with the armature or field, or both, is varied. Method 3 would be very wasteful, and is hardly allowable in good practice, because it is simply destroying the main current to put resistance in the armature circuit. Method 4, varying the resistance in the field circuit is very much less objectionable, and is very convenient and common (Fig. 3). This mode can be adopted with a very small loss of current, because the field current is only a small part of the total current used in the motor, and the loss of a portion of this small fraction is practically insignificant. Method 5, putting external resistance in series with both the armature and field is open to same objection as case 3, since it throttles and destroys part of the main current.

The next five modes of regulation, 6, 7, 8, 9 and 10, are theoretically more economical than the preceding, because we vary the internal or useful resistance instead of adding external or dead resistance. Method 6, in which the internal resistance of the armature is varied, is very difficult to carry out in practice, simply because it is hard to get at and change the connections of the armature while it is revolving. One of the few ways devised to accomplish this is to wind the armature with two or more circuits connected to a corresponding number of commutators, whereby one or more of these circuits may be used, thus varying the internal resistance and torque. This is clumsy, and practically little better than using two or more separate motors.

Method 7, cutting out the field-coils in series is a very simple and common plan. It is the ordinary way of regulating constant-current or other series-wound motors. This method, or some modification of it, is one according to which the constant-current or "arc" motors of the Baxter, "C. and C." and Excelsior companies are constructed. Method 8, of cutting out field-coils in multiple arc, is shown in Fig. 1, and is especially applicable to shunt-wound motors. The different layers, for example, may be respectively connected to the contact points of a switch and thrown into circuit successively, the innermost layer first, etc., thus obtaining the most economical result.

Method 9, of grouping the field-coils in series or multiple arc produces very great variations in field resistance, and is a combination of the two preceding cases. Like them, it consists in winding the field with separate circuits, which are connected to a switch. This is employed in street car motors to obtain the great variations in resistance and power required of them.

Method 10 is also merely a combination of two or more of the four preceding cases. A simple way of carrying it out is illustrated in Fig. 5, and consists in connecting the armature and field either in series or in multiple arc, by which a great variation in the total internal resistance of the machine is obtained.

The next method, No. 11, is open to the same objection as No. 6, because when the armature is shunted the main current of the machine is affected. This is, however, less objectionable than dead resistance, because in most cases it is better to divert the current than to destroy it.

Method 12, like methods 4 and 7, is a useful and common one, because in shunting the field we are merely handling a very small fraction of the total current.

Method 13, varying a shunt in multiple arc with both armature and field, is wasteful, like No. 11. It was, however, the plan by which the first arc motors were regulated, a variable shunt being placed in the main circuit, and the motor connected to the terminals of the shunt.

The variations in the shunt, of course, throw more or less current through the motor, thereby varying its power as required.

Method 14, varying the current in a separately-excited field, is merely historical, as this class of motors has gone out of use. The plan, however, is a very effective one, because, of course, it is very easy to control the field current when it is produced by a separate source.

Method 15 is shown in Fig. 7, and consists in shunting the field magnetism—*i.e.*, diverting the lines of force from the armature through some other path. In the arrangement shown in Fig. 7, there is a simple series-wound motor with consequent pole field-magnet, and if the coils exciting one magnetic circuit are short-circuited, it is evident that the magnetism produced in the other magnetic circuit will be short-circuited or shunted by the former. The short-circuiting of the coils is effected by the variable shunt, as indicated.

Method 16 is very similar to the preceding, and consists in short-circuiting the field magnetism, and diverting it from the armature by a keeper, which may be moved towards or away from the pole-pieces by means of a screw or other contrivance.

We now come to methods 17, 18, and 19, in which the line of commutation is varied. The first is the well known plan of shifting the brushes. This is very effective and easily carried out, and has, therefore, been used quite extensively; but it has the very serious and almost prohibitory objection that when the brushes are moved from the neutral point they spark very badly. This may be remedied to a slight extent by some heroic plan like blowing out the spark produced. But, as sparking is one of the worst drawbacks of a motor, it hardly seems as if this method of regulation would be permanent.

Methods of regulation which are all right for dynamos may not be allowable in the case of motors, because the former is usually in the hands of skilled men devoted to their care, while motors are often run by ignorant and careless persons.

Method 18, shifting the commutator, is simply another way of doing the same thing as shifting the brushes.

Method 19, shifting the magnetic resultant or direction of lines of force in the armature, may be accomplished by two sets of pole-pieces, the relative magnetic strength of which is varied. This is also open to the same objection as shifting the brushes.

Method 20, shown in Fig. 10, consisting in moving or separating the pole-pieces from the armature, had been used in the Diehl and other motors, but it is rather difficult to carry out mechanically, and introduces a hinge or joint in the magnetic circuit, which is, of course, very undesirable.

Method 21, moving the armature away from the pole-pieces, is very much easier to accomplish mechanically, and has a great many advantages as a means of regulation. Mr. S. S. Wheeler and myself have been working for some time on motors in which this method of regulation is employed, and the results we have obtained have been very satisfactory; in fact, we have found it to be extremely simple, effective, and reliable.

The second table gives a list of the possible cases of motor regulation which may occur with direct or continuous currents. There are four supremely important quantities or conditions in connection with electric motor regulation, viz., potential, current, speed, and load, and it is with reference to one or more of these that practically all motors are designed, built, sold, and used. Motors are always distinguished, both in science and in trade, as constant-potential or constant-current motors; constant or variable speed motors, and con-

Digitized by Google

stant variable load motors; hence a classification of motors based upon the constancy or variability of these four factors is very convenient, and at the same time scientifically correct. The second table is made upon this plan, and in it the four quantities are represented by their initial letters, P, C, S, and L, expressed respectively in volts, amperes, revolutions per minute, and torque in pounds at one foot radius, these being the units ordinarily used in practical as well as scientific work. We find that there are in all sixteen different cases, in the first four of which the potential is constant; in the second four the potential and current are both constant, in the third four the current only is constant, and in the fourth four neither the current nor the potential is constant.

Case 1, in which the potential alone is constant, is the case of a series-wound motor, for example, with variable load on a constant-potential circuit. Such a motor would rise in speed when the load was reduced, and *vice versâ*. It would not be at all self-regulating—in fact, it would tend to run at a very high speed with light load, and a very low speed with a heavy load. It is possible to give various other examples, but one is sufficient in most cases. In this case, however, I may say that the ordinary street car motor, fed from a constant-potential circuit, is also an example of case 1, the current being controlled by varying the external or internal resistance, according to one of the methods given in the first table.

(To be continued.)

PHYSICAL SOCIETY.—June 8.

Prof. AYRTON, F.R.S., Vice-President in the Chair.

Dr. Bond and Mr. Bretton were elected members, and the following communications were made:

A "Photograph of Lightning Flashes" was exhibited and described by Dr. Hoffert. The photograph was obtained during the storm on the 6th inst. whilst the camera was being waved about in the hands, and shows three similar and parallel flashes, thus proving that successive sparks in multiple flashes may traverse the same path and may be separated by appreciable intervals of time. The supposed primary spark is intersected by numerous tributary ones spreading out on both sides; the second spark one tributary, and the third none. Faint bands of light pass across the plate parallel to the direction of motion, and these prove that some residual illumination exists during the intervals between the successive flashes. Evidence of a dark flash is also presented by the plate.

Prof. Herschel, who had taken photographs during the same storm, referred to the fluttering appearance of the flashes, and on their long duration—in many cases the time was sufficient to allow him to direct the camera towards the flash and make a successful exposure. He had also observed multiple flashes with the unaided eye, and on waving his hand about he had sometimes noticed about a dozen distinct images of it during one discharge.

Mr. Gregory said that he watched the storm along with two others, and they could seldom agree as to the shape of the flashes, or on their simple or multiple character. The want of agreement as to multiplicity he thought might be caused by their eyes being directed towards different parts of the sky when a multiple flash occurred; the one who happened to be looking towards the flash might be conscious of only one impression, whereas the others in directing their eyes would receive the flashes on different parts of the retina. In some cases as many as three distinct flashes (occurring at intervals of about ten seconds) traversed the same path, and a number of the discharges presented a beaded or striated appearance. The beads seemed to remain after the main flash had faded, and this might account for the beads shown in Dr. Hoffert's photograph.

Mr. C. V. Boys, in referring to multiple flashes, said that although his statements made in the discussion of Mr. Whipple's paper on April 13th were not readily accepted, yet no one who watched the recent storm could doubt their existence.

Prof. S. P. Thompson thought the order of the flashes on the photograph may have been the reverse of that supposed, for he observed that the bands of light extended on both sides of the (so-called) primary flash, whereas the outside of the third flash was quite dark.

Mr. E. W. Smith noticed many cases of "sympathetic discharge," in which a flash in the north seemed to precipitate another in the N.W. within a few seconds, and in this he was corroborated by **Mr. Gregory**, who viewed the storm from a different locality.

Mr. C. V. Burton thought the heating of the air by the first spark might give rise to the tributary sparks in subsequent ones.

Mr. A. W. Ward mentioned a long flash observed at Cambridge, which passed from the zenith and struck some farm building at a distance, and he was particularly impressed by the considerable time occupied in its progress.

"On the Methods of Suppressing Sparking in Electromagnets," by Prof. S. P. THOMPSON, D.Sc. The object of this paper is to classify the methods which have been suggested, and to draw attention to a novel method of some importance. The classification is as follows: (1) *Mechanical Devices.* (*a*) Simple snap switch. (*b*) Break in magnetic field. (*c*) Break under liquid. (*d*) Wiping break (asbestos, etc., brushes). (*e*) Blow out. *Electrical Devices.* (A) Use of condensers, (*a*) placed across gap; and (*b*) across terminal of magnet. (B) Mutual induction protectors, (*a*) copper sheet around core; and (*b*) layers of coil between winding. (C) Short-circuit working. (D) Differential winding. (E) High-resistance shunt (non-inductive). (F) Voltameter, or liquid resistance across gap. (G) Multiple wire arrangement of Mr. Langdon Davies. (H) Electromagnet with two bobbins in series or parallel. The merits and demerits of the different methods are indicated. The multiple wire arrangement used by Mr. Langdon Davies in his harmonic telegraph consists in winding each layer separately, and uniting all in parallel. The effect of this is to make the time-constants of the layers different, and on breaking the circuit the energy is spent in mutual discharges.

"A Shunt Transformer," by MR. E. W. SMITH. Two conductors, A and B, of equal impedance are placed in series between alternate-current mains, and the same mains are connected through two incandescent lamps in series. The conductor A has great resistance, and B has large self-induction, and when their junction is joined to that of the two lamps, both lamps become brighter and the main current is reduced. These phenomena were shown before the society. Since A may consist of lamps, and B may be a choking coil, the arrangement will serve to increase the P.D. between the terminals of the lamps without wasting much energy. Experiments of a similar nature has been made on a Mordey transformer, wound with three equal coils. One coil was used as primary, and the other two as separate secondaries, their respective circuits consisting of lamps and an alternate-current motor. Under these conditions the arithmetical run of the mean secondary currents exceeded the primary current by 14 per cent., the secondary volts were 8 per cent. less than the primary. All these experiments strikingly illustrate the effects of acceleration and lag in alternate-current circuits, and (as was pointed out by the author) show that meters registering "ampere-hours" merely may give readings differing greatly from the numbers representing the energy used.

COMPANIES' MEETINGS.

SUBMARINE TELEGRAPH COMPANY.

An extraordinary general meeting of this Company was held on Wednesday at the offices, Throgmorton-avenue, Sir Julian Goldsmid M.P., in the chair, to consider the confirmation of the resolution passed at the recent meeting for winding up the Company voluntarily under the Companies Acts, 1862 and 1867, and for appointing Sir J. Goldsmid, the Hon. Henry R. Brand, and Mr. S. M. Clare liquidators.

The **Chairman** said he believed that when they had gone through that meeting they would have done all that the Post Office had demanded of them. They had realised the reserve fund, obtaining for their investments about £28,000 in excess of their original cost price. This realisation had enabled them to make a distribution of assets among the shareholders, who had received their warrants for 75 per cent. of the capital of the Company. They had now to receive from the Post Office the money for the purchase of the cables, the house where they were then met, etc., and they had also to receive the money which the Paris and New York Company had to pay them for their interest in the Déolen cable. There would then be only one matter to complete—that was, to come to some arrangement with the Anglo-American Company as to the Salcombe cable. He feared that that matter would take the longest time to arrange. The liquidators would, however, do all they could to press forward the settlement. He concluded by moving the confirmation of the resolutions above mentioned.

The **Hon. A Ponsonby** seconded the motion, which was adopted.

Mr. Carmichael then moved a resolution to the effect that the remuneration of the liquidators be settled when they presented the account of the liquidation.

Mr. King seconded the motion, and expressed a hope that the expenses of the liquidators would be made to bear as lightly as possible on the shareholders. He considered that the Government had squeezed the Company most unmercifully.

The **Chairman** assured the shareholders that the liquidators would require no undue payment. In reply to other questions, he stated that among the assets of the liquidation would be their share of the earnings for the first three months of this year. He believed the shareholders would receive something over par—between 105 and 110; but until they had come to a settlement in regard to the Salcombe cable and the expenses he could not say what they would get. As soon as the liquidators had the money in hand to make a further considerable distribution they would do so.

The resolution was then unanimously passed.

A vote of thanks to the Chairman terminated the meeting.

GERMAN UNION TELEGRAPH COMPANY.

Sir James Anderson presided on Monday at Winchester House, Old Broad-street, over a general meeting of the members of the German Union Telegraph and Trust Company, Limited.

The circular of the liquidators intimated that a final payment of £2. 4s. per share would be made in exchange for their share certificates (making a total return of £9. 10s. per share in respect of the £10 held in the trust).

The **Chairman** said that the shareholders were naturally disappointed at not receiving a larger sum of money for their shares, or such a sum as was held out to them as probable a year ago. The

Digitized by Google

irony of fate had, however, been very hard upon them—so much so that since they sold the cable to the Government, and before the latter took its working over, there were two breaks which cost £13,000, or £1,400 less than the cost of the repairs of the whole previous 17 years. The liquidators had distributed all the money they had received, and thus would end the German Union Company, which had been very useful to the German Government and the public. He was bound to say that the German Government had used them better than their own Government had used the Submarine Company; and if the cables were going to fall into the hands of the Governments, he hoped they would be treated in the same way as the German Government had acted towards this Company, or perhaps a little better even. It was with great regret on his own pa:t, and on the part of the Directors, that he proposed the following resolution: "That the liquidators' account submitted to this meeting, showing the manner in which the winding up of the Company has been conducted, and its property disposed of, be received and adopted."

Count Reichenbach seconded the resolution, which was carried unanimously; as was also the following resolution: "That the books, accounts, and documents of the Company, and of the liquidators thereof, be retained by the liquidators, with authority to them to destroy the same after the expiration of one year from the dissolution of the Company."

A vote of thanks to the liquidators closed the meeting.

NEW COMPANIES REGISTERED.

Electricity Supply Corporation, Limited.—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100,000, in £10 shares (100 of which are founders' shares). Object: to apply for, obtain, undertake, and carry out a provisional order for the supply of electric light and power within the parish of St. Martin's-in-the-Fields, in the county of Middlesex, and also generally any contracts, acts, provisional orders, licenses, decrees, and concessions for, or in relation to, the supply of electricity in Great Britain or elsewhere; to carry on the business of electrical engineers, electricians, engineers, and contractors, manufacturers of electrical and other apparatus, etc. The first subscribers are:

	Ordinary shares.
J. Irving Courtenay, 1, Elm-court, Temple, E.C.	1
J. Barclay, 5, Clarendon-place, Hyde-park-gardens	1
Sir D. Cooper, M.P., 6, De Vere-gardens, S.W.	1
L. W. Novelli, Oxford and Cambridge Club, S.W.	1
J. Meston, 75, Union-street, Aberdeen	1
F. D. Finlay, 70, Gloucester-place, W.	1
F. King, 65, Chelverton-road, Putney	1

There shall be not less than than five nor more than 10 Directors. Qualification: 50 shares, the first to be appointed by the subscribers to the memorandum of association. Remuneration to be determined in general meeting.

Electricity Supply Company for Spain, Limited.—Registered by Slaughter and May, 18, Austinfriars, E.C., with a capital of £100,000 in £5 shares, of which 100 are founders' shares and 19,900 ordinary shares. Object: to form centres in any towns and districts in the Kingdom of Spain, at which electric power may be generated or accumulated, and from which the same may be distributed by means of wires or other conductors of electricity for the purpose of lighting private houses or street lighting, or the lighting of public buildings, shops, factories or works, or for the purpose of giving motive power or heating in all such places. The first subscribers are:

	Shares.
R. Hammond, 117, Bishopsgate-street Within, E.C.	1
W. May, 18, Austinfriars	1
H. E. Warner, Beechcroft, Streatham Common	1
H. Mann, 12, Woburn-place, W.C.	1
W. A. Mann, 7, St. Helen's-gardens, North Kensington, W.	1
T. E. Towerson, F.C.S., 1, Portland-road, Finsbury Park	1
H. St. J. Winkworth, 22, Clareville-grove, South Kensington	1

There shall not less than three nor more than seven Directors. The first to be appointed by the subscribers to the memorandum of association. Qualification: £250 stock. Remuneration: £500 per annum, together with one-tenth of the net profits after 7 per cent. dividend, divisible as they determine.

Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited.—Registered by Newman, Hays, and Co., 31, Abchurch-lane, E.C., with a capital of £120,000, in 15,000 priority shares of £5 each, and 9,000 founders' shares of £5 each. Object: to purchase, take over, resell, and work the whole or any of the foreign or colonial patents, and provisional specifications for foreign or colonial patents of F. E. and A. S. Elmore, and all improvements thereunder relating to the treatment and electrical deposition of copper and other metals, and for the manufacture of all kinds of metal articles. The first subscribers are:

	Shares.
Sir J. H. Morris, K.C.S.I., 88, Queen's-gate, S.W.	50
J. M'Farlan, Invermay, Wimbledon	50
E. Carron, Rydal, Surbiton-hill-park	50
F. L. Rawson, 11, Queen Victoria-street, E.C.	1,150
J. H. Ward, 11, Queen Victoria-street, E.C.	1
R. Jones, Lily Lodge, Hampstead	1
W. Rawson, 68, Cornwall-gardens, S.W.	1

There shall not be less than three nor more than 11 directors. Qualification: 50 shares; the first to be appointed by the subscribers to the memorandum of association. Remuneration: £1,500 until the board exceeds seven, when it shall be £2,000, with 5 per cent. of net profits after 10 per cent. dividend.

CITY NOTES.

West African Telegraph Company.—A dividend of 5s. per share is announced by the Directors of this Company, in respect of the year ended December 31 last.

Mining and General Electric Lamp Company, Limited.—The works address of the above Company is now at 64, Millbank-street, Westminster, to which place goods or communications should be sent.

West India and Panama Telegraph Company.—The traffic receipts of this Company for the half-month ended June 15th are £3,157, as compared with £2,971 in the corresponding period of 1888.

South of England Telephone Company, Limited.—In the report of this Company for the year ended April 30, the Directors recommend a distribution of 1 per cent., leaving a balance of £627 to be carried forward.

Eastern and South African Telegraph Company, Limited.—This Company notify that the coupons, due July 1 next, on their 5 per cent. mortgage debentures will be paid on and after that date at the banking-house of Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E.C.

PROVISIONAL PATENTS, 1889.

JUNE 11.

9589. **Improvements in electric signals for indicating the direction and speed of revolution of engine shafts.** James Clark Ricketson, 52, Chancery-lane, London. (Complete specification.)

9659. **Improvements in and connected with electric batteries.** Arthur Harry Norman, 4, South-street, Finsbury, London.

JUNE 12.

9667. **Improvements in apparatus for the generation of electricity.** George Wilkinson, 2, Princes-mansions, Victoria-street, Westminster.

9681. **Improvements in electrical storage or secondary batteries.** Roger Tatham, 4, Clayton-square, Liverpool.

9713. **Improvements in electric conductors.** James Grieve Lorrain, Norfolk House, Norfolk-street, Strand. (La Société d'Exploitation des Cables Electriques Système Berthoud, Borel et Cie., Switzerland.)

JUNE 13.

9743. **Improvements in field magnets of dynamos and electro motors.** Charles Richardson, 74, Barrett-street, Brooks Bar, Manchester.

9745. **Improvements in or relating to dynamo-electric machines.** Wilfrid Swanwick Boult, 24, King's Mount, Birkenhead, Cheshire.

JUNE 15.

9828. **Improvements in secondary voltaic batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

SPECIFICATIONS PUBLISHED.

1888.

8525. **Electric trembling bells.** Rawson and John. 8d.

10092. **Supplying electricity to tramcars, &c.** Lineff. 11d.

10654. **Electric arc lamps.** Mortimer and Holloway. 8d.

11749. **Electric lamps.** Sellon. 8d.

12858. **Distributing electric energy.** Zipernowsky and Deri. 8d.

1889.

3881. **Regulating electric currents.** Balet. 1s. 3d.

4960. **Administering electricity.** Lawrance. 8d.

5912. **Suspending electric conductors.** Van Depoele. 8d.

6804. **Telephone transmitters.** Lake (Straton.) 8d.

6865. **Secondary batteries.** Heyl. 4d.

NOTES.

Llandudno.—The pier and pavilion at Llandudno are now lighted by electric light.

Conversazione.—The conversazione of the Society of Arts will take place to-night (Friday), at the South Kensington Museum.

Dundee.—The order for the electric lighting of the Albert Hall, Dundee, has been placed with Messrs. Paterson and Cooper.

Isle of Man Telegraph.—In the House of Commons on Thursday, June 20th, the Telegraphs (Isle of Man) Bill was passed through Committee.

Cuba.—The Thomson-Houston Company have put up a fine plant in Cuba for public lighting, consisting of 1,000 incandescents and 100 arcs.

Society of Arts Medals.—The silver medal of the Society of Arts has been awarded to Prof. Silvanus P. Thompson for his paper on "Arc Lamps and their Mechanism."

Sentence for Electric Sugar Frauds.—Howard was sentenced at Washington, on June 21, to nine years and eight months in a State prison for complicity in the electric sugar frauds.

Munich.—The electric light is very much appreciated in Munich. There are now 116 installations, fitted by nine firms, comprising a total of 588 arcs and 23,231 incandescent lamps in the town.

Electric Light in Mines.—The Llay Hall Colliery, Gwersyllt, is now fitted with electric light. There are 65 incandescent lamps in use, of 16 and 32 c.p., lighting the pithead, yard, crossings, offices, and workshops.

Electrical Exhibition.—A correspondent to the *Birmingham Daily Post* points out that sections Q to V in the exhibition at Bingley Hall will be at a disadvantage from want of sufficient access, unless the transept is continued into that avenue.

Errata.—Two somewhat curious errors crept into our last number. First we referred to Prof. Houston instead of Prof. E. Thomson as being at Paris; and gave the motto of the R. A. S. as "experience" instead of "Science with Practice."

New Cables.—The manufacture of the new Halifax-Bermuda cable is now in progress at Henley's Telegraph Works Company, North Woolwich. A Danish and a West Indian cable manufactured by the same firm, are also nearly ready for shipment.

The Column Printing Telegraph.—The Exchange Telegraph Company, Limited, notify that they are the sole proprietors of patents for column printing instruments, and will take legal proceedings against all persons using or selling instruments which are infringements of the same.

River Party.—It is proposed to hold a river party in connection with the Old Student's Association on the Thames above Sunbury, on Saturday afternoon, July 13. Inclusive tickets will be about five shillings, and ladies are specially invited. Further details of the Hon. Sec., 14, Garfield-road, Lavender Hill, S.W.

Edinburgh.—At the last meeting of the Edinburgh and Leith Gas Commissioners, a motion was notified: "That it be remitted to the Works Committee to consider and report as to what attitude the commissioners should assume towards electric light companies proposing to supply electric light and power for the citizens of Edinburgh."

Palais des Machines.—The heat from the steam-pipes and engines in the machinery gallery at the Paris Exhibition is a very serious drawback, especially as the weather now tends to become hotter. M. Vigreux proposes to instal large ventilating fans driven by electricity on a system similar to that adopted in the Hotel de Ville at Paris.

Paris Exhibition.—The proposition to permanently preserve the buildings at the Paris Exhibition has met with favour amongst the authorities, and the question having come before the Municipal Council on the 18th June, it was decided "that the prefectoral administration be invited to negotiate with the State for the preservation of the buildings of the Exposition of 1889 situated in the Champs de Mars."

Reading.—The Thomson-Houston arc lamps in Reading have awakened the gas company to action, and they have approached the Corporation with the proposition to supply more light to the streets. The Town Council, however, appear to be in favour of electric light. The majority are willing to enter into a five years' contract, under Messrs Laing, Wharton, and Down, for 30 arc lamps of 1,400 c.p., at £27 per annum, to be kept lighted all night.

Electricity on the Metropolitan Railway.—The Committee of the House of Lords on unopposed Bills passed on Monday last the Bill of the Metropolitan Railway Company, which, among other powers, authorises the company to use "electricity on their railways or any mechanical or other power other than steam power, either in addition to or in substitution for steam power." This Bill has already been sanctioned by the House of Commons.

Cable Repairing.—The India Rubber, Gutta Percha, and Telegraph Works Company has just received a telegram from Mr. Matthew Hamilton Gray, engineer in charge, saying that the cable steamer "Silvertown" had successfully removed three faults from the cables connecting Dakar (Senegal) with Teneriffe without interrupting the working of the lines. As one of these faults was in the neighbourhood of Teneriffe and the other two near Senegal, some 800 nautical miles southward, and the work was carried out in about 10 days, those engaged in the operations are to be congratulated on their success. The "Silvertown" is expected to arrive in London on 5th prox.

The Electric Carriage.—After the parade of the cattle before their Royal Highnesses the Prince and Princess of Wales and the Royal Family, at the Royal Agricultural Show at Windsor on Wednesday, His Royal Highness, being interested, asked that the electric carriage of Messrs. Immisch and Co. might be brought before him by a member of the firm, who explained the principle and action of this mode of locomotion. Their Royal Highnesses appeared greatly pleased with the simplicity of the details, and at the ease with which the carriage is driven and guided, the motive force being supplied to the accumulators from one of the Immisch electric launch charging stations now lying in the Thames off Windsor.

Electric Light in Pall Mall.—At a meeting of the St. James's Vestry, on Thursday, June 20th, the Lighting Committee recommended: "That Messrs. Trinders and Co. be informed, in reply to their notice of the intention of the St. James's and Pall Mall Electric Light Company to apply for a provisional order, under the Electric Lighting Acts, in the next session of Parliament, that the Vestry are not prepared to assent to the said company applying for a provisional order until they have acquired a generating station in the northern part of the parish, or are otherwise in a position to supply electricity throughout the whole parish." Mr. W. Jenkins moved the adoption of this recommendation, which was agreed to.

Plante's Researches.—The news of the death of M. Gaston Planté has been received throughout the country with feelings of the deepest regret. It is strange that although his genius and ability were universally recognised, so little is known of his very able book entitled "The Storage of Electrical Energy," which contains a description of all his experiments with voltaic batteries, which finally led to the well-known form of Planté cell. Besides his experiments with all the common metals, as voltaic couples, there are extremely interesting articles on the discharge of high-tension currents and globular lightning. It is doubtful if this latter subject has ever before been treated so completely, or with so many well-authenticated instances, which stands beyond dispute. The book cannot be too strongly recommended to all who have to do with secondary batteries, as it contains notes by the original inventor on the practical management of accumulators, and explains all the small but important difficulties which are so often met with, but which may be easily remedied and avoided by a little knowledge of their theory.

A Cheap Electric Current Regulator.—The *Scientific American* describes a cheap instrument, invented by Frank J. Crouch, of Eugene City, Oregon, for regulating electric lights, so that they can be turned up and down, as with gas or oil. A vessel is employed containing a saline or other chemical solution, and in connection therewith are diverging conducting arms connected in circuit with the main line and insulated, a central arm being adapted to be lowered into the solution to any desired depth, the brilliancy of the light being decreased or increased as the central rod is raised or lowered. A rack enables the plunges to be moved up or down. A shunt circuit connects the wires of the system, this circuit having a resistance coil made to balance the lamps used on the circuit, and the coil having a switch, to cut off communication between the coil and the shunt circuit. It is said that an instrument containing only three gallons of the liquid will readily regulate 80 lamps of 30 c.p. each, and it is stated that such instruments have been used for more than a year past, with great satisfaction, to theatres and elsewhere.

The London Electric Supply Company's Mains. The Electric Lighting Committee of the Rotherhithe Vestry reported that Union-road and Lower-road had been scheduled as the thoroughfares in the parish within which the London Electric Supply Corporation were to lay mains within two years, and that £1,000 had been deposited.—At the St. Olave's Board of Works, the clerk reported that the Board of Trade had scheduled Tooley-street, Duke-street, Mill-lane, and a portion of Shad Thames as the streets in which the electric light mains must be laid within two years, and that the company had deposited £1,000.—At the St. Saviour's Vestry, the Paving and General Purposes Committee reported that they had considered the letter from the Board of Trade, requesting to be provided with a list of streets in which, in the opinion of the Board, the London Electric Supply Corporation should be compelled to lay mains within a specified time, and had named the following—viz., Borough High-street, Southwark-bridge-road, Blackfriars-road, and Southwark-street. After discussion, the recommendation was adopted.

Juries at Paris.—The name of M. Marcel Deprez has been added to the members of the jury on electrical exhibits at the Paris Exhibition. The names of the members for foreign sections are: Messrs. Preece and Aylmer (England), Rousseau and Gody (Belgium), Turettini (Switzerland), Abdank (United States), and Hering (Russia). The officers are M. Mascart, president; Preece, vice-president; Potier, general reporter; Turrettini, secretary. The jury is divided into four sections: 1. Machines, transformers, instruments—MM. Fribourg, Hering, Potier, Sciama, Turrettini. 2. Telegraphy, telephony, signals, cables, wires—MM. Aylmer, Marcel Deprez, Jossoulin, Preece, Trottin. 3. Lighting, arcs, fittings—MM. Huet, Postel-Vinay, Rau, Rousseau, Sautter. 4. Electro-chemistry batteries, accumulators, bells, various—MM. Abdank, H. Fontaine, Gody, Mascart, Sebert. The final awards of the juries will take the following forms: 1, grand prize; 2, silver medal; 3, bronze medal; 4, honourable mention; 5, recommendations. The judgments will be based, as far as possible, on the conception of the idea, originality, and ingenuity of construction; construction—character of work and finish of detail; efficiency—electrical or mechanical; industrial value—cost price and maintenance.

Paddington and the County Council.—At the meeting of the Paddington Vestry on June 18, Mr. Mark H. Judge moved the following resolutions, which were agreed to with two dissentients: "That the Vestry of Paddington having considered the letter of the London County Council of June 5, 1889, addressed to the Board of Trade, on the subject of electric lighting, takes the strongest exception to the proposals therein made for transferring the control and purchase of electric lighting in the metropolis from the City Corporation, the Vestries, and the District Boards to the County Council, and this for the reasons which were detailed." "That this Vestry do place on record its opinion that the County Council has exceeded its functions in agreeing to proposals for interfering with the powers of the metropolitan representative governing bodies without first giving them an opportunity of considering such proposals." "That the foregoing statement of objections be forwarded to the Board of Trade, the County Council, and the other representative governing bodies of the metropolis, and the members of the County Council for Paddington." "And that the City Corporation, the Vestries, and the District Boards be asked to inform the Board of Trade and the County Council of their views on the proposals referred to."

The Proposed Electrical Exhibition in Edinburgh.—The first public meeting of the promoters of the Electrical Engineering and Inventors' Exhibition, which it is proposed to hold in Edinburgh next year, took place last Friday. Sir Thomas Clark, Bart., presided. The Chairman moved a resolution remitting the matter to an executive committee to carry out the scheme, and to report

Digitized by Google

progress to a future meeting of the promoters, which was adopted. The chairman said he hoped they would succeed in getting the project into proper shape. There could be no doubt that such an exhibition would be very useful, for they could not conceal from themselves the fact that electricity was to be a very important force in the future as it had to an extent been in the past. Mr. Hall Blyth, in seconding, said he thought a much nearer site than that proposed at Gorgie should be obtained. Mr. A. R. Bennett expressed the view that the proposed site possessed exceptional advantages. It was centrally situated for the railways and tramways, while the Union Canal would afford a means of illustrating water power. Mr. Hall Blyth said the site would be the life or death of the exhibition, and the question should be remitted to the executive committee to consider very carefully. This was agreed to, and the proceedings terminated.

Glasgow.—A special meeting of the Town Council of Glasgow was held on Monday to consider a recommendation of the Gas Committee as to electric lighting. The committee reported the receipt of a notice on behalf of Messrs. Muir, Mavor, and Coulson, Limited, of their intention to apply for an electric lighting order applicable to Glasgow. The committee agree to recommend that notices should be given, before the 1st prox., by the Lord Provost, magistrates, and Council as such, and also as police authorities and as gas trustees, of their intention, either conjunctly and severally, or one or other of them, to apply for a provisional order to supply electricity for public and private purposes within the area comprised within the municipal boundaries of the city. It was pointed out that for some years very little had been done by Corporations in regard to electric lighting; but owing to the adoption of the Electric Lighting Acts, they were becoming more active. Many large towns in England had been in the same position as Glasgow, having allowed private companies to start without having Parliamentary powers, who were now coming forward and applying for provisional orders. It was asked if, in the event of the provisional order being obtained, it would be actually carried out, or would it be used merely to block the way when other parties were applying? Mr. Ure pointed out that they could not possibly obtain this provisional order without giving guarantees that they would carry it out. The recommendation of the committee was then adopted unanimously.

London County Council.—The London County Council held their first ordinary meeting after the Whitsuntide recess on Tuesday afternoon, in the Guildhall Council Chamber, under the presidency of the Earl of Rosebery. The Chairman informed the Council that a letter had been received from the Board of Trade thanking the Council for their kindness, and the assistance it had given in the matter of electric lighting, and sending a copy of a model order proposed to be followed in the case of all the electric lighting applications now before the Board of Trade. The matter would be reported by the Highways Committee, probably at the next meeting of the Council. The Board of Trade stated that if the Council desired to bring any points in the order under the notice of the Board, the Board would be glad to receive representatives of the Council and to confer with them on the subject. Perhaps the Council would authorise the Highways Committee if it should think necessary to depute representatives to confer with the Board of Trade, and to suggest, on behalf of the Council, any alterations they might think desirable. The Chairman's suggestion was adopted. At the meeting on Wednesday, the Highways Committee reported that they have directed the letter from the Board of Trade, dated June 13, to be printed, and a copy to be sent to each member of the Council. The model provisional order referred to therein has been considered by the committee, with the assistance of the Council's officers and the Parliamentary agent; and, as the committee deemed some amendments desirable, they have, under the authority given to them on the 18th inst., requested their chairman and Mr. Benn, one of the members of the committee, to confer with the Board of Trade with a view to the amendments being made in the order.

Reduction in Incandescent Lamps.—The Edison Swan Company notify us that on and after July 1st, an important alteration in the tariff of charges for incandescent lamps will take place. The retirement of the Edison-Swan Company from the field of installations, and their devotion solely to incandescent lamps, instruments, and fittings, is not unproductive of result in meeting the requirements of the trade, and we only echo the widespread feeling of satisfaction in welcoming this step in the cheapening of the electric light. In view of the general interest to electrical engineers of such a reduction, we have no hesitation in printing the tariff *in extenso*.

Edison Lamps.

Nominal c.p.	E.M.F.	Tariff.
8	48 to 55 volts	3s. 9d.
10	89 „ 105 „	3s. 9d.
16	89 „ 105 „	3s. 9d.
32	89 „ 105 „	4s. 3d.
50	89 „ 105 „	5s. 3d.

Edison-Swan Lamps.

Nominal c.p. Miniature and Surgical Lamps.	E.M.F. in volts. E.M.F. to order.	Tariff.
1	3 to 8	3s. 9d.
2½	5 „ 8	3s. 9d.
2½	9 „ 25	3s. 9d.
5	10 „ 35	3s. 9d.
8	15 „ 25	3s. 9d.
8	26 „ 55	3s. 9d.
16	30 „ 105	3s. 9d.
25	45 „ 105	4s. 0d.
32	55 „ 105	4s. 0d.
50	80 „ 105	5s. 0d.
100	80 „ 105	7s. 6d.
200	80 „ 105	10s. 0d.

500	80 „ 105	17s. 6d.
1000	80 „ 105	30s. 0d.

Lamps not specified above, or which in any way vary from the standard lamps, are to be charged at a higher rate than those above stated. We understand that a new and complete lamp list is in preparation.

Electricity in China.—The news reaches us that a telephone has been put up at the palace of the "Seventh Prince." This is encouraging news from the capital of China, though telephones are not new to Peking, as several short lines have been set up experimentally within the past seven years. They have even been used at the Great Wall of China (the very existence of which wall was disputed not long ago), as well as in the Buddhist temple of the Azure Cloud, some few leagues to the north of the capital. The fact that the telephone is making its way into the palaces constitutes a distinct step in advance, and it is to be hoped they will speedily find favour in the eyes of the *literati*; among the mercantile population of the Southern ports they have long been accepted as useful aids to commerce. Electric lighting is likely to have a grand

Digitized by Google

future in Hong Kong now that regularity of supply can be depended upon, and before long the system is certain to spread to all the open ports. It is matter for regret that the uncertainty and oft-repeated failures which attended the earlier installations gave rise to so much delay, for Chinese merchants are always willing to embark capital in any undertaking which can be made to pay a dividend, when they are not interfered with by the mandarin element. We venture to say that those who knew China 20 years ago are now agreeably surprised to find our Western inventions have begun to take root even to the trifling extent already witnessed, for, as a rule, the progress made, though slow, is sure. For all that, we should like to see a little more life put into affairs out there, for we have proof that vital changes may be rapidly effected, without danger to the country or the individual, when we turn to China's enterprising neighbours, the Japanese, regarding whom there were such dismal prophecies a few years ago. It was freely asserted then that Japan was going ahead at a pace which could not last, but the change, stupendous though it undoubtedly was, has been permanent and beneficial in the highest degree, and has resulted in the development of large markets for English goods in that country.

Royal Meteorological Society.—At the last meeting of this society, held on Wednesday, the 19th inst., Dr. W. Marcet, F.R.S., president, in the chair, Mr. W. Marriott gave a very graphic and interesting account of the recent thunderstorms which have prevailed over this country. On Sunday, June 2, a thunderstorm passed across the country in a northerly direction from Wiltshire about 3 a.m., and reaching Edinburgh by 10.44. It travelled at the rate of about 50 miles an hour. It is possible that this storm travelled still further north, and reached Kirkwall at 3.37 p.m. A severe thunderstorm prevailed over the neighbourhood of the Tweed between 11 a.m. and noon, and was accompanied by hail of very large size, some of the stones being five inches in circumference. A very destructive storm occurred over the whole of the North-West of England and South of Scotland during the afternoon. Much damage was caused by lightning, and very large hail fell over an extensive area. Some of the hailstones measured seven inches in circumference, and weighed seven ounces. During the night of the same day a severe thunderstorm prevailed over Norfolk, which was also accompanied by very large hailstones, some of which were five to six inches in circumference. On Thursday, the 6th, thunderstorms prevailed during the afternoon over the whole of the South-East of England; that which passed over the metropolis about nine o'clock was remarkable for the brilliant and continuous display of lightning. During the same night, and in the early morning of the following day, a very destructive storm prevailed over the Eastern Counties, much damage being done by the lightning in the north-west of Norfolk. Severe hailstorms occurred between 2 and 3 a.m. both at Margate and Ipswich. During the afternoon of the 7th, destructive thunderstorms prevailed over the whole of the Southern Counties, much damage being done by lightning, while at Tunbridge Wells there was a most remarkable hailstorm—one of the hailstones, which was weighed, was actually half a pound in weight. An interesting collection of over 40 photographs of lightning, taken during the storm on June 6, was also exhibited to the meeting. In addition to the sinuous, ribbon, and meandering flashes of lightning, several photographs showed knotted, multiple, and dark flashes.

Leeds Proposed Central Station.—The following are additional details of the report of the Electric Lighting Committee of the Leeds Corporation, to which we alluded last week. The report begins by reminding the members of the Council that at its meeting held in May, 1883, the sum of £10,000 was granted to the committee "to carry out an experimental system of electric lighting within and about such portions of the municipal buildings as the committee may consider desirable," and then explains at some length how the money has been expended, and with what success. The total expense incurred up to the present has been £10,233. 18s. 11d., or practically the amount originally voted. Continuing, the report goes on to say that whilst the Council's instructions to the committee were limited to making experiments in and about the Town Hall, in compliance with a generally expressed wish, it has deemed it its duty to go into the question of lighting with electricity the centre of the town. Until recently distance has precluded lighting large areas from central stations, but this difficulty has been removed by an improvement which enables high potentials and small mains to be used in place of low potentials and large mains. To secure the best possible method the committee has visited various towns where the electric light is used, and then sought information from the tenants of shops bounded by Albion-street, Boar-lane, Briggate, and Commercial-street, to ascertain the disposition of the tradespeople in regard to an electric light supply. The desire to have the electric light was almost unanimous. The committee then mapped out the district bounded by Vicar-lane, New Market-street, Duncan-street, Briggate down to the Bridge, Boar-lane to the New Station, Park-row, Guildford-street, Upperhead-row, New Briggate, and North-street to Vicar-lane; and, after ascertaining the exact number of lamps which would be required in a given area, and using this as a basis, it was found that the number of public and private lamps required for lighting this district would be about 37,500. The piece of land known as "The Midden" has been fixed upon for the central station, and tenders show that the machinery and other plant required will cost in all about £58,000. To supply private residences, however, would cost an additional £10,000, making in all £68,000. The committee point out, however, that whilst the latter amount would be required to carry out the whole of the scheme described, the electric lighting station would consist of a unit or initial plant, which might be multiplied from time to time as the demand for the light increases. For this reason, they would not advise this central lighting installation for Leeds to be, in the first place, larger than would involve an expenditure of £25,000. As to the question of cost, the committee is of opinion than an incandescent 10-c.p. lamp can, after paying for depreciation and interest, but not making a profit, be run for one-eighth of a penny per lamp per hour. Comparing this with the present price of gas in Leeds, electric lighting can be supplied at 20 per cent. above that price; but as the customers would have in addition to pay for renewing their lamps, this would probably add 40 per cent. to the total cost, according to the present price, or, taking gas and meters at 2s per 1,000ft., the electric light would in price be equal to gas at 3s. 5d. per 1,000ft. But the great advantages of electric lighting when compared with gas lighting as affecting health, goods, furniture, books, decorations, etc., and the absolute freedom of the electric light from explosions and personal injury, must be borne in mind.

ELECTRIC LIGHTING AND TRANSMISSION OF POWER IN MINING.*

BY T. M. WINSTANLEY-WALLIS, A.I.E.E.

I.—ELECTRIC LIGHTING.

The application of electricity to mining (neglecting the familiar signals and exploders) may be divided into two heads—transmission of energy (*a*) for the purpose of lighting, and (*b*) for performing mechanical work.

The former is fairly well known, and is being employed more and more every year; amongst coal mines this rapid extension is mainly due to the fact (1) that the cost of electric lighting is practically the cost of steam power; (2) that the lights do not require individual attention; (3) that they do not flicker in the strongest wind; (4) that any candle-power from five to a thousand is easy of attainment on the same circuit; and (5) that no lighting, turning out, or trimming is required.

For underground lighting, the incandescent lamp is very valuable; in that strong currents of air do not affect it, that it will not fire gas when intact, and that it is nearly impossible for it to cause an explosion, even when broken accidentally.

In speaking of incandescent lighting, the writer should premise that he is referring to what is known as the low tension" or "low pressure," or "parallel" system. There are, broadly speaking, two ways in which electric lamps can be connected up: the "parallel" and the "series" systems. The system almost invariably used for incandescent lighting is the "*parallel.*" In this, two main wires run from the terminals of the dynamo, and the lamps are connected so as to form separate bridges between the mains; the dynamo maintains a constant electrical pressure between these mains; then, if the mains are bridged by a lamp offering a certain resistance to this pressure, a current (proportional directly to the pressure and inversely to the resistance of the lamp) will flow through it, and it will give a certain light; if another lamp is bridged across, of, say, half the resistance of the first one, obviously since the pressure is constant, double the current will flow, and double the amount of light be produced.

From this it will be seen that practically any number of different sizes of lamps can be used on the same circuit, and all lamps are independent of each other.

Lamps "in parallel" are extinguished or lit by interrupting or completing the circuit of the lamp between the mains. The "parallel" system is in no way dangerous to life, the pressure being only that required for one lamp, and the volume only of the current being increased as additional lamps are lit.

On the "series" system, the lamps are connected up one after the other in a continuous circuit. The positive terminal of the dynamo is connected to the first lamp, the first lamp is connected to the second lamp, and so on through the whole circuit to the negative terminal of the dynamo. Thus the same current passes through all the lamps in succession; the lamps are extinguished by giving the current an alternative path of lower resistance than the lamp, by connecting a wire to the main on each side of the lamp. This system is usually employed for long distance lighting with arc lamps, such as town lighting. With any considerable number of lamps in circuit it is dangerous to life; for since the same current passes through the entire circuit, the pressure increases in proportion to the number of lamps alight. There are several other methods of connection which, however, need not be discussed here.

The writer now proposes to enter into some calculation of the working cost, since that is the most important point in considering a system of lighting, and will take as an example a plant of the size recently installed at the Cossall Colliery, Ilkeston, under his supervision, of a capacity equivalent to 100 × 16 c.p. lamps. He will assume that, of the equivalent of 70 × 16 c.p. lamps on the surface, 26 will burn for 3,000 hours per annum, and the remainder (44) for 400 hours per annum.

Of the equivalent of 30 lamps underground, 20 will burn 3,000 hours per annum, and the rest (10 in number) for 7,000 hours; these latter are lamps which run continuously. (It may be stated here, that for easy calculation, the standard incandescent lamp at 16 c.p. is taken, and all lamps, though many will be of greater power, are reduced to the equivalent number of 16-c.p. lamps, which will take the same engine-power.) The total lamp-hours per annum of the above specified lamps will be about 222,000; to get the horse-power hours per annum, we may divide this by 10, since 10 × 16 c.p. lamps take 1 h.p. to drive them

	£	s.	d.
Assuming that a horse-power hour can be obtained for 10lb. of slack coal at 1s. 6d. per ton, the amount for coal will be, say, 110 tons	£8	5	0
Renewals of lamps on surface burning 3,000 hours twice per annum	8	10	0
Renewals of lamps on surface burning 400 hours ½ times per annum	2	5	0
Renewals of lamps underground burning 3,000 hours twice per annum	8	0	0
Renewals of lamps underground burning 7,000 hours 4½ times per annum	9	0	0
Interest and depreciation at 10 per cent. on capital outlay of £200	20	0	0
Oil, water, waste, etc.	5	0	0
	£61	0	0

This does not include the cost of an attendant for the dynamo, as, if not driven from the fan-shaft and looked after by the fan engine man, the small amount of attention required can be usually provided at a trifling cost.

	£	s.	d.
The gas used at 5 cubic feet per hour per 16 c.p. for 222,000 lamp-hours, multiplying by 5, will be 1,110,000 cubic feet, and this at 2s. 6d. per 1,000 cubic feet will cost	£138	15	0
Interest and depreciation of fittings and pipes, etc., say...	11	5	0
	£150	0	0

This is without any allowance for labour in lighting, etc., or leakage, which latter is a very serious item in a colliery, particularly when taken down the shaft. As yet arc lighting has hardly been mentioned.

Perhaps the greatest advantages of the "parallel" system are that every lamp is independent, and that, given a sufficiency of power and of dynamo capacity, any size of lamp can be run on the same circuit, and this applies to arc lamps as well as to incandescents.

On the "series" system it is obvious that, since large and small arcs require practically the same pressure, and since the same current traverses all the lamps, they must all be of the same size.

Arc lamps, however, though they cannot conveniently be smaller than 400 or 500 c.p., are much more economical than incandescents in the ratio of power consumed to light produced. For example, for 1 h.p. an arc lamp will give 1,000 c.p., a large incandescent 250 c.p., and small incandescents about 160 c.p. To set off against this, an arc lamp has the disadvantage that, while a 250-c.p. incandescent will last 1,000 or 1,500 hours, and need no attention, and then can be renewed for about 18s., a 1,000-c.p. arc in the same time will cost quite £3 in carbons and attendance. It should be stated that incandescents of various sizes can be run on a series circuit, as, though the current is constant, the pressure can be varied.

An accumulator or storage battery is a valuable adjunct to an installation, as it provides against possible stoppage through belts or ropes breaking, and, moreover, doubles the output of the plant if the dynamo is run to supply current at the same time as the accumulator is discharging; it is also a great convenience in private installations to charge during the day, and run off the accumulator at night.

The cost of an accumulator for the plant considered above, to run the whole of the lamps mentioned for 10 hours, will about double the cost of the plant, and increase the running cost by nearly 20 per cent.

In addition to the lighting functions of an electric light plant, the current can be utilised for signals, for firing fuses for blasting, etc., and power can be got by putting a motor on the circuit in exactly the same way as a lamp. This latter is a very valuable property, as a small fan or pump can be fixed for temporary work, and cables run to it in a few hours. The writer has heard people frequently say that "they should wait till more improvements were made before adopting electric light." It would, of course, be absurd to say that improvements will not be made continually in details, but this is going on in every other branch of engi-

* Paper read before the Chesterfield and Midland Counties Institution of Engineers.

Digitized by Google

neering. The dynamo is the main thing, and a well-constructed dynamo of average size will give a useful return of 90 per cent. of the power put into it. This does not leave any great margin for improvement; and, if it *is* to be improved, it may be fairly said that perpetual motion is within the range of possibility.

It should be noted that collieries possessing an electric lighting plant are in a position to adopt electric safety lamps at a small outlay—referring, of course, to lamps using storage batteries, such as the Edison-Swan, Pitkin, and others, as it is not probable that lamps with primary batteries will be extensively used till zinc costs as little—weight for weight—as coal.

The following is a list of most of the collieries in Great Britain using electric light, for which the writer is indebted to the various Government inspectors of the districts:

List of Collieries Using Electric Light.

Derbyshire (6).

II.—Transmission of Power.

Electrical transmission of power depends on what is known as the reversibility of the dynamo, which principle may be stated thus: a dynamo, if the armature is rotated by mechanical power, will generate an electric current, and if supplied with current will give out mechanical power just as an engine, if driven by another engine, will act as a pump, and if supplied with water under pressure, will give out power on its shaft.

This analogy also holds good, since a good engine by no means makes a good pump, nor does a good dynamo necessarily make a good motor.

When an electric motor is running, it has also a tendency due to its rotation to generate a current in an opposite direction to the current driving it; this produces a back pressure which checks the driving current; thus, when running free, this back pressure limits the current through the motor to the amount necessary to overcome its own friction; when a load is thrown on, the speed is slightly checked, and the back pressure thereby reduced, thus allowing a larger current, and one proportional to the load, to pass, and keep the motor up to its work.

From this it will be seen that an electric motor possesses great power of starting under a load, since when the motor is at rest the back pressure is zero, and a large current can pass; and since the torque, or turning effort of a motor, is proportional to the volume of current passing through it, an electric motor can exert at starting four or five times its normal power.

The losses of power in a system of power transmission are three: firstly, in the generator; secondly, in mains; and thirdly, in the receiver or motor.

In an electric transmission plant, the losses in the generator and motor together vary from about 40 per cent. in small machines, to as little as 10 per cent. in large ones. The loss on the mains depends on three quantities: the distance, the size of the main, and the volume of current; the loss may be regarded as being caused by something of the nature of frictional resistance of pipes, since it consists of a loss of electrical pressure in forcing the current through the wire. It is obvious that, other things being equal, the loss will vary directly as the distance.

With regard to the other two considerations, the resistance offered by a wire to the passage of the current is proportional inversely to the sectional area of the wire; thus, with a given current flowing along a given wire, and taking a certain amount of pressure to force it along, if the cross section of the wire is doubled, the amount of pressure required will be halved; also with a given wire, if the current is doubled, the amount of pressure required to force it through the wire is also doubled.

Now the energy of an electric current is made up of two factors—the pressure and the volume; taking a current of a certain pressure and volume, we shall get exactly the same amount of power if we double the volume and halve the pressure, and *vice versâ*. Thus it will be seen that since the loss on a given wire increases with the current, we must work with as high a pressure as is feasible; and also, since the loss decreases as the size of the wire increases, we must have as large a wire as possible. The limit in one direction is the pressure, which cannot be exceeded without danger to life, and in the other the size of wire, which will cost more in interest on capital cost than the annual cost of the horse-power expended in forcing the current through it.

At collieries, the cost of power is so small that it is generally advisable to have a rather large loss in the wire, and so use a small wire, and save in capital expenditure.

Electrical transmission of power is very flexible; it is possible to have motors of from one to 100 h.p. or over working on the same circuit. If a movable motor is required, it can be mounted on a truck, which can also carry a drum of cable to be paid out as the motor is moved.

The maintenance of a generator or motor must necessarily be less than that of any reciprocating engine, since the two bearings have no alternate push and pull to stand, but simply a continuous rotary motion.

Motors which require to be moved can be made to weigh as little as 70lb. per brake horse-power, and this with as high an efficiency as heavier stationary machines; and without any governing appliance, an electric motor will maintain a constant speed between no load and full load within 1 per cent. or 2 per cent.

Electric locomotives, either to carry their own power in the shape of secondary or storage batteries, as at the Wharncliff Silkstone Colliery in Yorkshire, or to take their current from a fixed conductor by a rubbing contact are coming into use, and an incidental advantage of electric transmission is that light can be obtained from the same circuit.

It may now be advantageous to compare shortly the most generally used systems of power transmission.

Transmission of power to a distance in mining is usually accomplished in one of five ways; by steam, wire rope, compressed air, water under pressure, and electricity. The

Digitized by Google

writer does not propose to consider either steam or hydraulic transmission—as steam is wasteful, and only applicable for short distances on account of condensation; and hydraulic transmission is usually inconvenient on account of the effluent water, and inefficient where less power than the full capacity of the motor is required. He will, therefore, discuss only the comparative advantages and costs of wire rope, compressed air, and electrical transmission.

There are three points to be considered : capital cost, working cost, and convenience.

For short distances, quick-running wire rope is far the best on the first two heads. On the third head, it has always the disadvantages of requiring the guide pulleys to be oiled, and loss of power when deviating from a straight line, as well as great wear and tear. Slow-running rope is shown by the statistics of the cable tramways to only give a useful return of 25 per cent. to 30 per cent.

Air compressors and motors are always inefficient, and there is a large percentage of loss in the mains, while the first cost is rarely less, and under most circumstances greater than that of electrical plant; the mains are expensive to lay down, and not easily shifted when the position of the motor requires to be changed, and there are practically two sets of bearings, brasses, etc., to be kept in repair —the one counterbalancing advantage, as far as the writer is aware, being the ventilation secured by the exhauster in driving headings, etc.

The capital cost of electrical transmission plant is usually rather less than that of compressed air, and for long distances, also less than that of wire rope. For shorter distances, under about three-quarters of a mile, wire rope is cheaper in capital cost; and it is more economical in working up to about one mile, after which electricity has the advantage.

As far as convenience goes, electricity leaves little to be desired. The conductor, or main, is easily laid and requires no attention. When fixed, there is no loss of power in sharp bends, the efficiency is as great when lightly loaded as when working at full power. The motors are small for their power, and can be shifted from place to place, or worked on a truck with a drum of flexible cable, to admit of any desired movement for coalcutters, portable pumps, fans, etc.

The comparative merits of the various systems, however, depend on a combination of the capital and working costs, which is given in the form of a table, showing the cost of 1 h.p. transmitted to various distances.

The table is quoted from a paper by Mr. W. Geipel, of Edinburgh :

Total power trans-mitted.	System.	Distance in Yards.			
		110	1,100	11,000	22,000
H.P.					
5	Electric....	2·25	2·41	3·29	5·20
	Pneumatic	2·70	3·30	9 53	16·70
	Wire rope......... .	1·13	1·83	10·40	22·70
100	Electric.............	1 79	1·91	2·63	4·08
	Pneumatic	2·00	2·09	3·10	4·50
	Wire rope...........	1·07	1·22	8·83	9·73

From this it will be seen that electricity is far ahead of both the other systems considered at long distances, and for short distances, though surpassed by wire rope, it is well ahead of compressed air, and it is, besides, more convenient than either.

The writer will now give a few particulars of electrical transmission plants at present working.

At Trafalgar Collieries, Forest of Dean, a pump lifting 35 gallons per minute 90 feet, at a distance of half a mile, has been worked by a motor for five years, and a pump lifting 120 gallons per minute 300 feet high, at a distance of 2,200 yards, for over a year. The pump of the latter is a double-throw, with 9in. plunger and 10in. stroke, driven at 25 revolutions per minute by spur gear, reducing 6 to 1, and the small pinion is driven from the motor by a belt.

The current is carried by a $\frac{19}{18}$ copper cable on insulators, the return cable being an old 4in. wire rope. The efficiency from generator to motor is nearly 60 per cent., and the total cost per annum is £408; the water power, which was superseded, having cost £878. At these collieries a 6ft. fan is worked by a motor at a distance of one mile.

At St. John's Colliery, Normanton, a set of pumps lifting 120 gals. per minute 900 feet high, has been working since the beginning of 1888, with an efficiency between dynamo and motor of about 60 per cent. The output of the dynamo is 53 h.p., and the horse-power in the water 33. The loss in gearing, pumps, and water friction is 13 h.p., and the loss in the cables 2·5 h.p.

Finally, 50 h.p. is transmitted electrically to Solothurn, in Switzerland, from a water power at Kriegstetten, five miles distant, with an efficiency of nearly 75 per cent. These figures are sufficient to show that electrical transmission is not inefficient; its convenience is best proved by experience, which the writer hopes will not be wanting in the immediate future among colliery managers.

THE ELECTRIC LIGHTING OF BRISTOL.

MR. PREECE'S REPORT.

About a fortnight since Mr. Preece, the well-known electrical engineer of London, met the Bristol Sanitary Committee, and discussed with them the feasibility of lighting the city by electricity. After a long conversation, it was decided that Mr. Preece should prepare a report on the subject, and this has now been issued to the members of the Electrical Committee, accompanied by a letter intimating that the contents of report should not be disclosed until it had been dealt with by the committee. We learn, however, that Mr. Preece's report is of a very lengthy character, and very general in its terms. It refers to what has been done in other towns in the matter of electric lighting and the results that have been obtained. He admits that electricity cannot compete on very fair terms with gas. It cannot be supplied as cheaply as gas. His experience in the Post Office at London was that a gas-burner giving a 10-candle light cost about 18s. per annum, and an electric lamp giving the same amount of light, which, by the way, was maintained more uniformly and with comfort, cost 22s. per annum. That might be taken, Mr. Preece says, as the difference in cost. As a motive power, he points out that electricity could be obtained cheaper in Bristol than in London and other places on account of the price of coal in this centre. Mr. Preece's view is that the electric light is undoubtedly the light of the future. He did not anticipate it would in the least do any harm to gas, because there were various means to which gas could be applied. Mr. Preece supplies numerous statistics of the installations elsewhere, and says it would probably require a capital of £300,000 to undertake the business in Bristol. The Corporation would have to look the matter boldly in the face, but at the same time Mr. Preece states that the only Corporation which had undertaken the electric light was Bradford in Yorkshire, and as they had no experience of the management by a Corporation of the light, it behoved the Bristol Corporation to consider the matter very carefully. There were advantages in the Corporation undertaking the matter because they could get the money on advantageous terms; the light could be supplied at the lowest price to the consumer, and any profit arising could be applied to the reduction of the rates. Mr. Preece seems to favour the alternate current system which had been introduced in the lighting at Liverpool, Taunton, Exeter, and Bath.

STARTING OF THE BARKING-ROAD ELECTRIC CARS.—The first of the Electric Traction Company's cars, having been duly licensed by the police authorities and the Board of Trade, commenced running on the Barking-road section of the North Metropolitan Tramway Company on the 14th instant. A second car was put on the following day, and the six cars, which will shortly entirely supersede horses, will be placed in active work as soon as the drivers become accustomed to the new form of traction. These cars carry 52 passengers, and do 17 journeys daily, with one change of accumulators.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

The index of the current volume is given with this number, and every purchaser should receive it free of cost.

We commenced our report of the Paris Exhibition with a general article on the exhibits in our last issue, and the descriptions of special exhibits will appear from time to time till the whole have been described.

Specimen copies of the paper will be sent on request.

ELECTRICAL ENGINEERS AT PARIS.

The party of American engineers which have recently been welcomed by their English colleagues, and have now gone to the Great Exhibition to see how their French professional brethren order this kind of thing in their country, consists nominally of civil, mechanical, mining, and electrical engineers, but in reality the electrical portion of the profession is very inadequately represented. America can boast of a larger number of distinctly electrical engineers in proportion to general engineers than any other country, and as these did not come with the present expedition it is safe to assume that they will come later on, and probably they will choose the time of the Electrical Congress for their visit to Paris. Our American cousins are far too practical to care much for the academic, not to say abstruse, questions which the organisers of this congress seem bent upon discussing, but the congress will be an opportunity for meeting electricians of almost every country, and, therefore, it may safely be predicted that the largest number of English and American electrical engineers will visit Paris at that time. We believe this state of affairs has already been taken into account by the Council of the Institution of Electrical Engineers, and if rumour may be taken to be a true forecast of the Council's intention, it would appear that there will be a Paris meeting of the Institution held during the time of the congress. This meeting will of course be largely attended by American electricians, and that the leading French electricians will also take part in it goes without saying.

As regards numbers only, the members of the Institution are likely to be in the minority at their own meeting, but this should not be allowed to interfere with the character of that meeting. If the meeting is to be a success and creditable to the Institution, it should be of the same character as the meetings usually held at 25, Great George-street, that is to say, it should be essentially of a practical nature. No abstruse problems should form the subject matter for papers or be allowed to be introduced into the discussions on practical papers, and especially all questions of nomenclature should be strictly forbidden. Such questions are likely to be discussed *ad nausum* at the congress, and the electrical industries will be none the better for all the vast amount of learned talk which will be poured forth on this occasion by the professors of abstract science for their mutual glorification. The idea of the Institution holding a meeting in Paris this year is a good one, and should be heartily encouraged by all English electricians, but on one condition, and that is that the meeting should be perfectly independent of the congress, and should be essentially practical in its character. There can scarcely be a question that amongst

Digitized by Google

European electrical societies, at any rate, the Institution takes the first rank. There is an International Society of Electricians in Paris, but it has only a kind of negative right to this title—namely, in so far as its proceedings are ignored by electricians of all nations outside the small group of French electricians who run it. In Belgium there is also an electrical society, but hardly to be compared with our Institution. The Berlin Society is somewhat better. It manages occasionally to secure a good paper, which is read outside its own circle of members, but the value of the papers is greatly diminished by the absence of anything like an adequate discussion. The society is completely under the control of a few large firms, whose representatives or servants are allowed to read papers, but are not allowed to discuss them, except in the most complimentary style, and anything like independent criticism is strictly tabooed. The proceedings of the Institution of Electrical Engineers are sometimes conducted in a warmer style than the sticklers for etiquette and decorum approve of, but they have, at least, the merit of being free and independent. Everybody is allowed to ventilate his views whether they be in accord, or in disaccord, with those of the "big firms," and in this freedom of discussion lies the principal value of the proceedings of the Institution. If a meeting is to be held in Paris let us have the same freedom of discussion, and let us have something worth discussing.

Now the question is, how can the latter condition best be attained? If the papers and the discussion thereon are to be supplied by the members of the Institution, there is no need to go to Paris to hold a meeting, since the same business could be transacted with very much more comfort and without expense in London. If the meeting is held in Paris it must be for some local reason. Now the only reasons which a scientific society has in organising a meeting are excursions to works and the securing of good papers, and in this connection we venture to make a suggestion to the Council of the Electrical Engineers which we hope they will take into serious consideration. They should make arrangements with French manufacturers of electrical apparatus for the inspection of their works, and they should endeavour to obtain, from French and other foreign authors, papers to be read at the meetings. There should be little difficulty in prevailing upon the various exhibitors of electrical apparatus to present to the Institution papers descriptive of them, and if the authors for commercial reasons should in some cases neglect to disclose all the scientifically important details, the process of free discussion which is a characteristic of the Institution, and to which we have already alluded, may be trusted to remedy the deficiency. The minutes of the Institution would thus become the most authentic and accurate record of the condition of the electrical industries in the year of the Great Exhibition, and acquire a practical value which can hardly be over estimated. We are quite aware that the programme we have here proposed for the Paris meeting of the Institution of Electrical Engineers will necessitate a considerable amount of work on the part of the Council and secretary of the Institution, and the success will also largely depend upon the exertions of the honorary secretary in Paris, but then the advantages which would result from this programme, not only to the Institution, but also to the electrical industries at large and to the French electricians in particular, are worth some little extra trouble. With Mr. Preece's and Mr. Aylmer's influence in Paris and with Mr. Webb's able and energetic co-operation at home, the success of the programme we have here briefly sketched may be confidently considered as assured.

THE MODEL ORDER.

The Board of Trade has issued a model provisional order, for a metropolitan order, in accord with the Electric Lighting Acts of 1882 and 1888 and the recent report of Major Marindin. As every firm and company desirous of obtaining such a provisional order must necessarily consult the idiosyncrasies of the Board of Trade, they will obtain this order therefore we may take it for granted that they either are, or soon will be, tolerably familiar with its clauses. We take it that this model is intended as a guide, and not to be too slavishly followed. Still there are clauses which must be common to all. The model must be more or less general, while each order granted will have to take into consideration the special character of the area over which the order extends. The Acts of Parliament and the regulations of the Board of Trade are intended, on the one hand, to facilitate the development of the industry by defining what may and what may not be done legally, and, on the other hand, to act as an arbitrator between the public and would-be "undertakers." Cannot some other word be found to express the people who desire to do the work, and this one be kept to its ordinary signification?

Besides this model order we have before us the orders granted to Messrs. Chamberlain and Hookham (Birmingham); the Liverpool Electric Supply Co. (Liverpool); and the Corporation of Swansea; from which it is evident that, as we say, the general portion of these orders is fashioned all on one principle, and many clauses are virtually the same. Each commences with a series of definitions which, though they may not be rigidly scientific, are practical, and continues with formal matters such as addresses and descriptions of undertakers, area of supply, etc., about which there can be few differences of opinion. Although a deposit has to be made to the

Digitized by Google

Board of Trade the money is released as the work proceeds, so that no hardship arises from locked up capital. In the case of Birmingham the deposit is £2,000, released £500 at a time upon the certificate of the Board's inspector as to work done ; with Liverpool the amount is not so predetermined, and in the case of Swansea, being a Corporation order, the capital case is altogether different. It would be well for those interested to carefully study these three orders, as well as the model of the Board of Trade. A most important set of clauses relate to "nature and mode of supply," because the question of "earth" plays a prominent part in all electrical distributions. Practically at present all "undertakers" use a complete metallic circuit. No earth returns can be permitted from the evil effects which would arise to telegraphic, telephonic, and other light or power distributing systems. The time may come, and that right soon, when the telegraph and telephonic systems will have to contemplate "no earth possible." This is one of the largest questions affecting the newer industries, as the tendency is to use very high pressures, and a leakage to earth that may be unimportant to the "light" people may play havoc with telegraphy and telephony. We are quite sure, then, that these clauses must be regarded as temporary only. With the next section other important questions arise, and unless the action of some of these is carefully considered, the case will arise when the "undertaker" under the order is in a worse position than the free lance who troubles about nothing but way-leaves. Neither existing Acts of Parliament, nor Board of Trade, nor County Council can say to the private contractor who has secured way-leaves, "Thus far shall thou go and no farther." These authorities can no more stop overhead wires erected as we have described than they can stop overhead telephone or telegraph wires, and this is as it should be, for, in our opinion, neither telephony, nor telegraphy (outside the Post Office system) should be allowed to claim vested rights in overhead wires or stop other industries from using similar wires. We are opposed, in such places as London, to all overhead wires, but if they are to be allowed at all, no restriction must be placed upon the industries that may utilise them. Returning to the "works" clauses, they may be taken to be an attempt to mediate between all the authorities interested, and, like all such attempts, will receive criticism all round, yet the unbiassed observer will be forced to admit the difficulties of the position, and acknowledge that every attempt to please all parties will probably end in pleasing none. The pith of the nine pages of clauses is that other people's interests must not be interfered with, and due notice must be given of interference with existing works, pipes, tram lines, bridges, streets, etc., etc., and when touched these must be put right again at the undertaker's expense. The following clauses relating to compulsory works must speak for themselves; we are unable to translate them into plain English:

"19. The undertakers shall, within a period of two years after the commencement of this order, lay down suitable and sufficient distributing mains for the purposes of general supply throughout every street or part of a street specified in that behalf in the second schedule, and shall thereafter maintain the same.

"20. In addition to the mains specified in the last preceding section the undertakers shall, at any time after the expiration of eighteen months after the commencement of this order, lay down suitable and sufficient distributing mains for the purposes of general supply throughout every other street or part of a street within the area of supply, upon being required to do so in manner by this order provided.

"All such mains as last above mentioned shall be laid down by the undertakers within six months after any requisition in that behalf served upon them in accordance with the provisions of this order has become binding upon them, or such further time as may in any case be approved of by the Board of Trade."

The section on testing seems very cumbersome, and we doubt if it is workable, but this question will have to be discussed at a future time at considerable length, and for the present we must leave these orders.

THE ROYAL AGRICULTURAL SHOW.

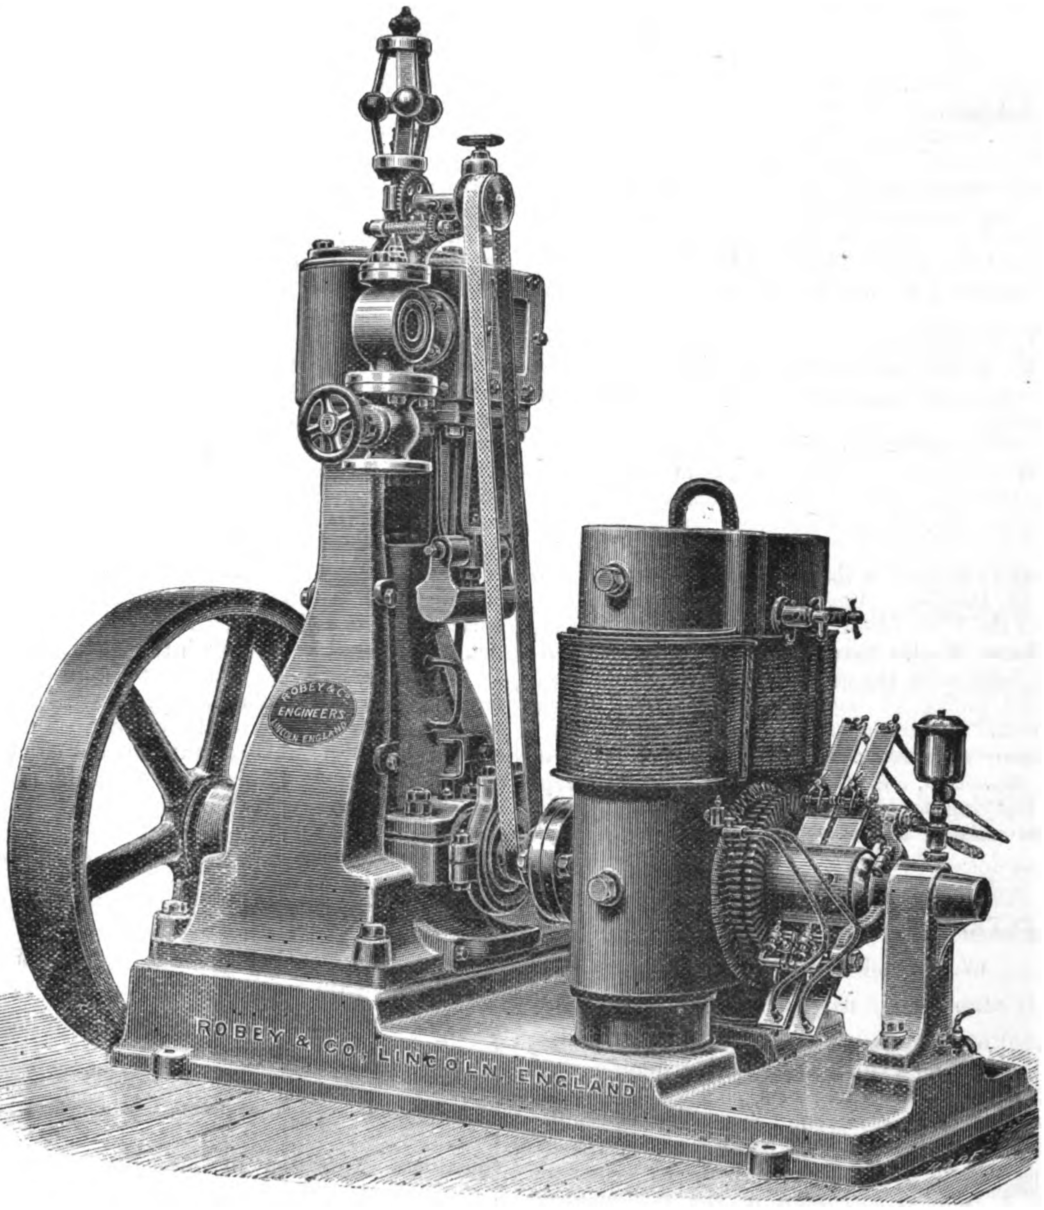
Year by year, as the Royal Show comes round, the exhibits of electrical apparatus, or of machinery concerned in the production of electricity, become more numerous. This year the site of the Show, which is one of the largest the Royal Agricultural Society have ever held, is Windsor Home Park. Prettier or more interesting surroundings there could hardly be, and owing to its accessibility from the metropolis, the attendance has been very large.

There is a splendid collection of engines on the ground, both steam, gas, and oil; and most of the big builders are represented. Taking them in alphabetical order, and dealing first with steam-engines, Messrs. Charles Burrell and Sons, of Thetford, Norfolk, exhibit a 16 h.p. compound undertype engine, fitted with automatic expansion gear controlled by the governor, and specially adapted for driving electric light machinery. Messrs. Clayton and Shuttleworth, of Lincoln, show an 8 h.p. portable, and a compound engine of 12 h.p. of the undertype class. Messrs. Davey, Paxman and Co., of Colchester, are well represented by engines of their well-known types, which we have so frequently described in these columns, and by their vertical Essex boilers, to which we referred in our de-cription of the Nottingham Show last year. Messrs. John Fowler and Co., of Leeds, have two engines, which we may specially notice, and hope in due course to illustrate and describe in detail—viz.: Scott's patent high-speed for dynamo driving, and a horizontal compound engine of 25 h.p., named the "Juanita," made for Colonel North, to be used in the installation at his house. It is fitted with automatic expansion gear on both cylinders, which is controlled by one governor, and has sight-feed and drop-sight lubricators and indicator gear. Mr. E. S. Hindley, of Bourton, D rset, always has a capital show of his small-power engines, and the present year is no exception to this rule. Messrs. R. Hornsby

Digitized by Google

AND SONS, of Grantham, besides their ordinary types, which are so well known to our readers, exhibit a new rotary engine, of which they hope great things. MESSRS. J. AND H. GWYNNE, of Hammersmith; MARSHALL, SONS, AND CO., of Gainsborough; RANSOMES, SIMS, AND JEFFERIES, of Ipswich; and RUSTON, PROCTOR, AND CO., of Lincoln, are firms who may be depended upon to supply good engines for any purpose.

Special attention has been given by many firms to the supply of engines to occupy a small space, run for long periods under considerable difficulties without giving trouble, wear well, cost little for maintenance, and be fairly economical steam users, in order to drive dynamos direct for ships' lighting. Among this class of engine, that shown by Messrs. ROBEY at the Royal Show (illustrated herewith) must take a very high place. The engine is intended to run at from 300 to 400 revolutions, and that exhibited is coupled to a Holmes's dynamo. The engine is thoroughly well built, and is spoken of with great praise by those who have used it. Every attention has been paid to lubrication, and the whole design and manufacture seems to have received the most careful consideration.



Robey Engine and Holmes' Dynamo.

Gas and oil engines are shown by MESSRS. J. E. H. ANDREW AND CO. of Reddish, Lancs., and London; THE BRITISH COMPANY, of Albion Works, Gospel Oak, N.W. (Atkinson's patent cycle); CROSSLEY BROS., Openshaw, Manchester (the "Otto"); DICK, KERR, AND CO., Kilmarnock, N.B., and London; J. H. KNIGHT, Barfield, Farnham, Surrey (a new paraffin oil engine); PRIESTMAN BROS., Hull (Priestman, Hume, and Eteve's petroleum engine, of which we illustrate a new portable form just brought out by the firm). This is a 6 h.p. (nominal) engine, and the makers claim that it is the first to be introduced as such to the public. In this form it is claimed that it is useful for many purposes, and in all cases where the portable steam-engine has hitherto been used, and as it requires no driver, and but little attention, it is likely to answer its purpose well. A 4 h.p. nominal horizontal type is exhibited, driving a 50-light dynamo, showing the utility of the engine for this purpose; the general design has been much improved upon, both as to compactness and otherwise, and the engine is now so constructed that every part is easily accessible. The third engine exhibited is a 1 h.p. horizontal type, similar in construction to the foregoing, but has an air compresser mounted upon sole plate at end of engine, and connected directly with same by gearing. This shows another application of the engine, which arrangement can be utilised for other purposes, such as pumping, etc. An improved method of supplying electricity for ignition purposes by means of a small storage cell, is also shown with the engines exhibited. The advantages of this improvement can be readily realised when it is considered the cell will last for about three months without being recharged. In connection with the dynamo before mentioned are exhibited some electrical plant provided by Messrs. Lea, Sons, and Co., of Shrewsbury.

Of turbines and water-wheels there are numerous exhibitors. MESSRS. GILBERT GILKES AND COMPANY, of Kendal, show a number of their useful vortex turbines, also a water-pressure reducer (Braithwaite's patent). MESSRS. J. J. ARMFIELD AND COMPANY, of Ringwood,

Digitized by Google

Hants, have brought out a new form of turbine, which they term the "British Empire." In this the water is admitted by means of double gates, working horizontally instead of vertically, which, so the makers claim, renders their working easier under a head of water. The turbine and water inlet is self-contained and ready for building into brickwork.

MR. C. L. HETT, of Brigg, Lincolnshire, has one of the best and most varied collections of turbines that has been seen at the Royal. One of these, "The Hercules," is only the second of this variety ever seen in England. It is destined for use in an electric light installation. Mr. Hett has had a large experience in turbine building, and if he cannot turn out a good one no one else can.

MESSRS. ABBOTT AND CO., of Newark-on-Trent, exhibit some of their "handy" hoists, which have come into use for elevating arc lamps. They are provided with two speeds capable of lifting 10cwt. and 20cwt. respectively. They are compact and neat.

MESSRS. T. J. SYER AND CO., of 45, Wilson-street, Finsbury, E.C., exhibit a new carpenter's bench with several improvements, among which may be mentioned instantaneous grip vices, screw stops, and a well down the centre, in which tools can be laid without interfering with the flat surface of the table. Messrs. Syer supplied six of these benches to the City and Guilds for their students' workshop.

MESSRS. W. F. DENNIS AND CO., of 11, Billiter-street, E.C., agents for Felten and Guilleaume, of Cologne, show their specialities on this occasion, chiefly, of course, of an agricultural kind.

In addition to a number of engineers' tools and sundries, MESSRS. W. H. WILLCOX AND CO., of 36, Southwark-street, S.E., exhibit specimens of their engine-packings and well-known lubricating oils, which have come largely into use for dynamos.

Pulleys were to be seen at the stands of MESSRS. J. and J. MACKIE, of Reading. MESSRS. F. MORTON AND CO., Liverpool, and the UNIVERSAL PATENT PULLEY COMPANY, Reading. Messrs. Mackie have introduced an interchangeable bush for pulleys, by the use of which no key is needed. Both bush and pulley are bored oval, and a dead grip is got by differential movement of the pulley on the wheel.

MESSRS. IMMISCH'S electric waggonette was a centre of considerable attraction, and their representative was kept very busy replying to the hundred and one questions of those who wanted to know "how the wheels went round."

ELECTRIC MOTOR REGULATION.*

BY FRANCIS B. CROCKER.

(Concluded from page 503.)

Case 2 is that of the ordinary shunt or differential motor, with a variable load on a constant-potential circuit. This is self-regulating and maintains its constant speed, as already stated, and is the commonest case of motor regulation met with. The current varies directly with the load.

Case 3 is that of the ordinary shunt motor with constant load, having a variable resistance in the field-magnet. This case is shown in Fig. 1. Increasing resistance of field circuit would weaken the field magnetism and the motor would run faster and take more current—*i.e.*, current would vary directly with speed.

Case 4 is not a practical one, because, if potential, speed and load are constant, the current cannot be varied without wasting it; that is, any excess of current would be simply destroyed, which, of course, is not permissible.

Case 5 is not likely to occur, because potential and current would not be constant with a variable load and speed, but if it did occur it would require that the speed and load should vary inversely.

Cases 6 and 7 are not practical for the same reason as given in case 4, because if potential, current and speed were constant the load could not be reduced without wasting electrical energy, and in case 7 the speed could not be varied without wasting energy.

* Paper read before the American Institute of Electrical Engineers. For the illustrations referred to see our last issue.

Case 8 is that in which all four factors are constant, and is best illustrated by a shunt motor with constant load on a constant-potential circuit, in which case the current and speed would also be constant.

Case 9 may be illustrated by a shunt motor with variable load on a constant-current circuit. The speed would run up as the load reduced. A more common example is a series motor on constant-current circuit, with switch for cutting out field-coils, or, in short, a constant-current motor with variable speed and load.

Case 10 is that of the regular constant-current or "arc" motor with governor, such, for example, as the Baxter or "C. and C." It is a series motor with a centrifugal governor which operates a switch to cut in and out the field-coils, as shown in Fig. 3. This is, next to the shunt and differential wound motors, the most common and important case of motor regulator.

Case 11 is that of a constant-current motor with constant load, with switch for vary field strength. The potential would rise directly with speed, but this case is not likely to occur.

Case 12 is not practical for the same reason as given in case 4.

The last four cases are those in which both potential and current vary. They are hardly practical cases, because electrical distribution is almost always either at constant current or constant potential. It is, however, of course, possible to have cases where both may vary, and examples of each case are given.

Case 13 is one which does occur to a certain extent in practice; for example, if a so-called constant-current circuit varies slightly, as it always does in practice—say, from nine to 10 amperes, then the current as well as potential is variable to that extent, and this must be taken account of in the regulation.

In the experiments which I have already referred to, Mr. Wheeler and I have built a motor of the constant current type which will govern for wide variations in current as well as in load. This motor, for example, will not fall in speed, even though the current be reduced from 10 to 5 amperes, which is a great variation for this type of motor, as the field and armature, being in series, the torque varies as the square of the current. This variation in current in the so-called constant-current circuits is a much greater percentage than the variation in potential of so-called constant-potential circuits, and amounts to $\frac{1}{2}$ to 1 ampere.

Having generally described the different cases of motor regulation, let us take up the mathematical relations of potential, current, speed, and load, which may be expressed quite simply.

Using the symbols P C S and L, as defined above, we have $P \times C$ as the total electrical energy supplied to motor in watts, or $\frac{P\,C}{746}$ in horse-power. Calling commercial efficiency a, the actual mechanical horse-power developed by a motor is $\frac{a\,P\,C}{746}$, expressed in electrical terms. The equivalent expression in mechanical terms is $\frac{2\,\pi\,S\,L}{33{,}000}$. Since the point at which load, L, is measured is 1ft. from centre of shaft, and travels $2\,\pi$ feet per revolution, or $2\,\pi\,S$ feet per minute. This, multiplied by the load and divided by 33,000, gives the horse-power developed by the motor.

Thus, we have $$\frac{a\,P\,C}{746} = \frac{2\,\pi\,S\,L}{33{,}000} = \text{h.p. of motor},$$

or $$P\,C = \frac{746 \times 2\,\pi\,S\,L}{33{,}000 \times a} = \frac{S\,L}{7 \cdot 04 \times a}.$$

For convenience, we may write $P\,C = \frac{S\,L}{7a}$ with an error of about one-half of 1 per cent.

If the efficiency, a, of motor is 85·2 per cent. the denominator, or $\cdot 04a$, becomes 6 exactly, and we have $P\,C = \frac{S\,L}{6}$; and if the efficiency is 75·8 per cent., we have $P\,C = \frac{S\,L}{5}$. The former is as high and the latter is as

Digitized by Google

low as is ordinarily met with in practical work; therefore, these are the limiting values.

The equation $P\ C = \frac{S\ L}{7{\cdot}04\,a}$, or one of the three simplified forms just given, may be advantageously used for solving problems in motor regulation. If we know any four of the quantities we may, of course, find the fifth by simply solving the equation with respect to it. It is also evident that if any three of the quantities are constant then the other two will vary directly or inversely with each other, depending upon their position in the equation. This is the ordinary case we have to deal with in regulation. Usually speed is required to be constant, either potential or current is maintained constant, and efficiency should be practically constant down to very small loads; thus we have either current or potential or load varying directly with load. The efficiency is rather a confusing element in motor regulation. For this reason it was not introduced as a fifth quantity in the second table, as it would have complicated it, and made a great many more possible cases. The efficiency should be high (close to 100 per cent.), and as nearly as possible constant, therefore it would not affect the figures much.

If the load or speed is zero, or very low, the potential or current should be correspondingly reduced, and the efficiency would remain constant. This is the condition for perfect regulation. Practically, it always takes some current to overcome friction, etc., even when load is zero, in which case efficiency is zero, but this current should be very small.

The equation $P\ C = \frac{S\ L}{7{\cdot}04\ a}$ applied to the cases marked "not practical" in second table, shows in case 4, for example, that if P, C, and L are constant, the efficiency, *a*, decreases directly with reduction in speed. This is not allowable. The same is true of the other cases, and shows that it is not proper to vary P C L simply at the expense of efficiency, or, in other words, waste current, to obtain regulation.

Having now given the general points of motor regulation, we will consider the forms of motors which are now being used extensively.

First and most important, we have the regular shunt motor for constant-potential circuit, which has already been referred to several times. Thousands of this type of motor are in use, and give very satisfactory results. A properly-designed motor of this kind will regulate within 5 per cent., which is near enough for most purposes. It has no regulating mechanism or complicated circuits to get out of order, and it may be called the ideal self-regulating machine. The next important form is the differential wound motor, which is even more perfect in closeness of regulation, theoretically, and it might be made almost absolutely constant in speed; practically, the speed varies about 2 per cent.

These are the figures given me by the company who manufacture these machines in the largest quantity and of the most excellent workmanship. Silvanus Thompson gives an example of one of these machines, which only varied ½ per cent. in speed, with a variation from 1·1 to 11·14 h.p.

The rule for winding differential motors is that the number of turns in the shunt divided by the number of turns in the series-coil are equal to the resistance of the shunt divided by the resistance of the armature plus the resistance of the series-coil. On this side of the Atlantic this is called Sprague's law of winding; on the other side it is called Ayrton and Perry's rule for winding. The slight variation in speed which does occur is due to the heating of the two coils and other slight disturbances. The shunt-coil varies considerably in resistance effected by heating; therefore the series-coil should have a few less turns than the rule requires. The heating of the shunt-coil weakens the current in it, and consequently the field magnetism, thus increasing the speed of the machine; therefore the motor runs faster after it has been running for some time. The proper way is, of course, to consider the true speed to be that which the motor has in steady running. At first, some trouble was experienced in this type of machine on account of short-circuiting between the series and shunt-coils, but this has been overcome by more perfect insulation.

The shunt or differentially-wound machines may be varied in speed by putting resistance in the field circuits, as shown in Fig. 1. This may, of course, be done automatically, or by hand, usually the latter.

The next important type of machine is the constant-current motor. As already stated, this is merely a series-wound machine, with switch for cutting in and out the field-coils, the latter being operated by an automatic centrifugal governor, as indicated in Fig. 3, or by hand. Various modifications of this type have been made—for example, a reversed coil may be wound on the field-magnet-coil and having a variable resistance in circuit with it. If this resistance is very high, the reversed coil has little or no effect. If this resistance is made very low, it will rob the main coil of its current, and also neutralise its effect, thereby greatly reducing the strength of the field-magnet. All these motors with varying field strength have the drawback that a certain time is required for the magnetism to vary, and the regulation is therefore sluggish. If we attempt to hasten this by laminating the field-core we have sparking at switch points, due to self-induction in field-coils.

Constant-current machines with regulator are now in great demand for arc circuits; in fact, it is not practical or safe to use a motor on an arc circuit without a regulator, as the danger of racing away is very great.

The differential winding of constant-current motors to maintain constant speed is not practicable. The solution of it requires either that the efficiency should be very low, or that storage batteries be used in connection with the motor to maintain a constant difference of potential. Any such plan as this is, of course, very objectionable.

The three types just given are really about the only continuous-current motors, used to any extent, in practice, and it seems that there is at present no demand for any other type.

Nothing has been said of the regulation of alternating-current motors, because it is a radically different subject, and, moreover, alternating-current motors tend to run synchronously, maintaining a constant speed and regulating themselves.

In conclusion, I would say that I would like to see this subject taken up by leaders in electrical science and given the attention which I think it deserves.

BIRMINGHAM ELECTRIC LIGHTING ORDER.

The Bill for confirming the Board of Trade provisional orders for electric lighting at Birmingham, Liverpool, and Swansea was issued on Tuesday as a Parliamentary paper. The Birmingham order, as agreed upon between the Board of Trade, the promoters, and the City Council, is granted to Arthur Chamberlain and George Hookham, of New Bartholomew-street, Birmingham, electrical engineers, but it is provided that none of the powers conferred by the order in relation to works or otherwise shall be exercised unless and until the undertaking has been transferred to a company duly constituted under the Companies Acts 1862 to 1882, or by a special Act of Parliament, and having a capital of not less than £50,000, and upon the transfer of the undertaking to such company that company shall be the undertakers for the purpose of the order. The area within which the undertakers are authorised to supply energy is described in Schedule A as follows: "So much of the borough of Birmingham as lies between the line formed by the following streets or parts of streets—namely, from the junction of Edmund-street and Easy-row, along Edmund-street to its junction with Livery-street, and thence along Livery-street to its junction with Colmore row, and thence along Colmore-row to its junction with Bull-street, and thence along Bull-street to its junction with the Minories, and thence along the Minories to its junction with the Old-square, and thence round the Old-square to the corner of the Upper-priory, and thence continuing round the Old-square down Corporation-street to its junction with Lawrence-street, and thence back along Corporation-street to its junction with Bull-street, and thence along Bull-street to its junction with Albert-street, and thence along Albert-street to its junction with Fazeley-

Digitized by Google

street, and thence along Fazeley-street to its junction with New Canal-street, and thence along New Canal-street to its junction with Bordesley-street, and thence along Bordesley-street to its junction with Park-street, thence along Park-street to its junction with Paternoster-row, thence along Paternoster-row to its junction with Moor-street, thence along Moor-street to its junction with Carr's-lane, thence along Carr's lane to its junction with High-street, thence along High-street and down the Bull-ring to its junction with Moor-street, thence across the Bull-ring and along Bell-street to its junction with Worcester-street, thence along Worcester-street to its junction with New-street, thence along New-street to its junction with Paradise-street, thence along Paradise-street to its junction with Easy-row, and thence along Easy-row to its junction with Edmund-street." The capital of the undertakers (being such company as above mentioned) for the purposes of the order is to be not less than £50,000, and the undertakers within a year from the commencement of the order, and before exercising any of the powers conferred upon them in relation to the execution of works, shall by special resolution cause such capital to be appropriated as a separate capital for the purposes of the undertaking; and if the undertakers fail to cause the capital to be subscribed and appropriated, the Board of Trade may revoke the order upon such terms as they think fit. The undertakers are also required within a year, or such extended period as the Board of Trade may approve, to deposit £2,000. The deposit will be repaid from time to time in sums of not less than £500, when and so soon as an inspector of the Board of Trade certifies that sums of that amount have been expended upon works for the purpose of the undertaking. The order contains clauses relating to the nature and mode of supply, and providing for the protection of various public interests. It is provided that the undertakers are within three years of the commencement of the order to lay down suitable and sufficient distributing mains for the purpose of general supply throughout every street within the specified area.

LEGAL INTELLIGENCE.

KING, BROWN, AND CO. v. THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION, LIMITED.

This is an action in the Court of Session, Edinburgh, before Lord Trayner, at the instance of King, Brown, and Co., Rosebank Electric Works, Broughton-road, Edinburgh, against the Anglo-American Brush Electric Light Corporation, Limited, 6, York-place, Edinburgh, for the reduction of letters patent obtained by the defenders in October, 1878, and other papers, for "improvements in apparatus for the generation and application of electricity for lighting, plating, and other purposes." The pursuers alleged that the defenders had threatened them with legal proceedings and liability in respect of the manufacture, use, or sale of the alleged invention said to be covered by the letters patent, and in particular of compound-wound dynamo machines. These threats, the pursuers said, had very seriously affected their business; and as, they alleged, the defenders' patent was anticipated by Varley, they were entitled to manufacture dynamos wound in series-shunt. In point of fact, they held that Varley had first discovered series-shunt winding, and that the defenders' alleged patent was therefore invalid. This was totally denied by the defenders, who maintained that they first discovered the series-shunt system, and that they were the first to apply it to its present purposes. A long proof was had some time ago, and on Wednesday Lord Trayner gave judgment.

He said: The question to be determined in this case is whether Mr. Brush is the inventor of (1) the peculiar form of commutator; and (2) the series-shunt machine for which the letters patent now under reduction were granted. In regard to both, the pursuers maintain that Mr. Brush is not the first and true inventor, and that both had been publicly known and used prior to the date of the letters patent. To some extent the determination of the question at issue depends upon the construction of Mr. Brush's patent obtained in 1878, and the patent obtained by Mr. Varley in 1876; to some extent also on matters of fact which are disputed. A long proof has been led before me from which it was not possible at the time to exclude evidence which ultimately resolved itself into expressions of opinion as to the meaning and construction of the two patents. In forming my judgment upon the questions submitted to me, I have carefully considered the proof, in so far as it was necessary thereby to instruct myself on scientific theory and detail, and in that respect I have obtained great assistance from the evidence adduced on both sides. I would like to add that I have been greatly assisted also by a remarkably able argument from both sides of the Bar. But in construing the letters patent I have put aside the different views of the witnesses on both sides, as construction is a matter for the Court, and not for the witnesses. In disposing of the case I shall deal separately with the questions connected with the commutators and the series-shunt machine.

First, as regards the commutator, Mr. Brush describes his invention in the provisional specification in these terms: "In constructing commutators cylindrical with an insulating hub or body to which are attached metallic sub-segments placed in electrical connection with the general mechanism in which the commutator is employed, and metallic wearing sub-segments detachably attached to said sub-segments." This is said to have been anticipated by Varley's commutator and the Manchester commutator, both of which have been produced. With regard to both of the last-mentioned commutators, I think it may be said that they are cylindrical, with metallic sub-segments having metallic wearing segments detachably attached. They also had an "insulating body"—or, I should rather say, "insulating substance," for the word "body" is ambiguous. Yet, with all those points of similarity, I do not regard them as anticipations of the defenders' commutator. The insulating hub or body of the defender's commutator is the "body" or basis on which his commutator is constructed, to which the various parts of his commutator are attached. This cannot be said of the Varley or Manchester commutator, in which the insulating substance does not form the body or basis of the commutator at all, and insulates not the whole commutator, but only one section of it. The purpose and effect of the Varley and Manchester commutators, electrically considered, were in my view the same as Brush's commutator; but it is not in that view that Brush claims that his commutator is a new invention. He claims it merely as a mechanical device or arrangement having certain advantages over existing arrangements used to serve the same purpose. But as a mechanical arrangement, I think it was new and useful, and not open to challenge. But the pursuers maintain that the letters patent under reduction are rendered invalid by reason of the patentee claiming in his final specification (as amended and disclaimed) something with reference to this commutator as an invention which is not foreshadowed in the provisional specification. The claim here referred to is the fourth, which is in these terms: "The commutator having metallic insulating segments T substantially as shown in division three." It appears to be necessary, or at least desirable and advantageous, to cut the armature bobbins out of circuit when they are crossing the neutral or current-reversing points of the magnetic field. To do this the continuity of the current-conducting segments of the commutators has to be broken, either by a mere space or by the insertion of some non-conducting material, at the given point. The cutting of the bobbins out of circuits was known and practised before the date of the defenders' patent; but it was not before then done by means of an insulated metal segment. The advantage which attaches to the defenders' method is this, that the insulated segment being metal like the conducting segments there is ensured a certain uniformity of wear over the entire surface of the commutator, which could not be preserved where a softer material like wood was used, or where merely a space was left. I am not aware that prior to the defenders' patent, any insulating body, metal or otherwise, was ever used, in the construction of the commutator, for the purpose of cutting the bobbins out of circuit. The insulating segment T of the defenders' patent was therefore a novelty, and its utility I do not understand to be disputed. But was it foreshadowed by the provisional specification? I think not.

In the first place, the defenders' second claim seems to me to be co-extensive with the provisional specification (in so far as it relates to the commutator) so that there was nothing left to claim under another head. If all that was foreshadowed in the provisional specification is included in the second claim, then the fourth claim (unless regarded as mere repetition, which nobody suggests) is for something not there foreshadowed. Secondly: the provisional specification relates only to the construction of a cylindrical commutator, whereas one of the chief purposes of, and one of the main advantages to be derived from, the insulating segment T is the preservation or maintenance of the cylindricity of the commutator: an object probably as important and as patentable as, but quite distinct from, the shape or mode of construction. Thirdly: the insulating segment T is not merely or necessarily a part of the cylindrical commutator having sub-segments with wearing segments detachably attached. It has and is intended to have a peculiar function which is not referred to in the provisional specification at all. Fourthly, it is said that the segment T is a part of the wearing segment, and therefore falls within the description of the provisional specification; but I think this is not so. The wearing segment is an essential part of the defenders' commutator. The segment T is not; it may be dispensed with altogether. I come, therefore, on this part of the case to the conclusion that the patent sought to be reduced is invalid in respect the invention claimed in the final specification is larger and different from that claimed in the provisional specification.

It is right, notwithstanding what I have said, that I should also express my opinion upon the remaining question in the case—viz., was Mr. Brush the inventor of the series-shunt machine, or had that invention been anticipated by Varley? For the pursuers it is maintained that Varley disclosed and published the invention of a series-shunt machine in his specification and patent of 1876, and constructed a machine in conformity with that specification, which was a series-shunt machine, and was publicly used as such in 1877. The defenders' patent, as I have said, is dated in 1878.

In considering whether the description given by Varley in his specification amounts to a publication of the invention claimed by the defenders, it is necessary to bear in mind the two different kinds of winding used in dynamos known at the time when Varley's specification was lodged. The first of these was the series. In the series machine, one wire was coiled round the magnets, and the current sent along this wire served both for the excitation of the magnets and the performance of the external work. There was thus one wire and one circuit. In the second—the shunt machine—there was again only one wire coiled round the magnets, but the electricity developed by the machine instead of being entirely conducted in one circuit (as in the series machine) was bifurcated immediately as it left the machine.

Digitized by Google

and one part went wholly to the excitation of the magnets, while the other went wholly to the performance of the external work. The current was thus divided in two, each part of which formed a branch or circuit quite independent of the other. The defects or weak points in each of these machines has been clearly explained by Mr. Imray, and need not here be repeated. These defects found their remedy in the third kind of machine now known as series shunt, which, speaking generally, is a compound of the other two ; it is in effect a series machine, with a shunt added to it. In this machine, the magnets are wound round with two insulated wires, one having a higher resistance (the shunt-coil) than the other (the series-coil). The electricity produced by the machine is diverted or bifurcated immediately after it leaves the armature ; part of it is taken by the shunt to magnetise the magnets, the remainder of it being conducted by the other wire (the series), so as to (1) excite the magnets and (2) perform the external work. The shunt-circuit is always closed, the other may be either closed or open. Thus, whether the series-circuit is closed and is exciting the magnets and doing external work, or is open and conveying no energy, the shunt-circuit is engaged in keeping the magnets sufficiently magnetised. For if the series-circuit is open, the only path from the armature being by the shunt more of the energy produced in the armature will pass through the shunt-circuit, and the effect of the shunt in exciting the magnets will be increased, thus compensating for the absence of any excitation from the series-circuit. The magnetisation of the magnets is in this manner maintained, so that the machine is kept ready to do full work on the series-circuit being again closed.

I turn now to Varley's description, which, for convenience, I here quote. He says, describing his machine : "Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light. There are several well-known ways of doing this, but the method I prefer is to wrap the soft iron magnets with two insulated wires, one having a larger resistance than the other. The circuit of large resistance is always closed, and the circuit of less resistance is used for the electric light. When the electric light is being produced, the greater portion of electricity passes through the circuit of less resistance, which I term the 'electric light circuit,' maintaining the magnetism of the magnets and producing the light. When the electric light circuit is opened from any cause, the electricity developed passes through the circuit of greater resistance only, and maintains the magnetism of the magnets." In this description I find disclosed (1) that the electricity developed by the machine is diverted or divided, one part going to maintain the magnetism of the magnets, and the remainder going to produce the electric light ; (2) that the method by which this may be accomplished (and the method which Varley prefers) is by wrapping the magnets with two insulated wires, one having a larger resistance than the other ; (3) that the circuit of larger resistance is always closed, and the current passing through it maintains the magnetism of the magnets ; and (4) that the current passing through the circuit of lesser resistance is used for "maintaining the magnetism of the magnets and producing the light." These four things appear to me to comprise every distinctive feature of a series-shunt machine. The series arrangement and the shunt arrangement are combined with the compensating or self-regulating result to which I have already alluded.

The defenders' scientific witnesses all express in their examination in chief the opinion that Varley did not disclose or publish the series-shunt arrangement in the description which I have already quoted. They find Varley's description to be inconsistent with series-shunt and suggestive of something quite different. The value of these opinions, however, is seriously diminished when consideration is given to the method by which they are reached. I think I do the defenders' witnesses no injustice when I say that their method is to take Varley's description paragraph by paragraph each by itself and detached from the context, and then proceed to show how each separate paragraph is, when so read, inconsistent with, or suggestive of something other than series-shunt. As an example of this method of dealing with Varley's description, I may refer to the evidence of Prof. Silvanus Thompson, the first witness examined by the defenders. Such a method is neither reasonable nor fair. To do justice to Varley's description it must be read in its entirety, and when this is done even Mr. Thompson has to admit, as he does on cross-examination, that the description is "consistent with the series-shunt arrangement, which is just a somewhat guarded way of saying that it is descriptive of a series-shunt arrangement. In like manner (but with a greater degree of fairness) Sir William Thomson deals with the description. He finds that there are some things inconsistent with series-shunt, that he "has been puzzled" in trying to understand the description which contains some words of a misleading rather than instructive tendency, and he concludes that an ordinary skilled workman would not in 1876 by Varley's description "have had disclosed to him the system of series-shunt winding." That opinion certainly undergoes modification in the course of his examination, for he concludes his evidence in chief (on this part of the case) by saying that he thinks "it quite probable that in 1876 he (the ordinary skilled workman) might have been led to series-shunt by these descriptions." His cross-examination, however, brings him still nearer to the view which I have taken. He says: "The whole passage is consistent with series-shunt winding except the partial inconsistency of the first lines, which is not an absolute inconsistency." On the whole, I think Sir William Thomson may fairly be claimed by the pursuers as a witness in support of their views.

A great deal of evidence is adduced to show that Varley's description would not have enabled an ordinary skilled workman to construct a series-shunt machine, although some of the defenders' witnesses say that from Varley's description it would have been difficult only, not impossible. But assuming the fact to be that from Varley's description alone the ordinary skilled workman could not have constructed a series-shunt machine, that is by no means conclusive of the question in the defenders' favour. A specification may so insufficiently describe the process or the machine patented as to render the patent invalid. It may, nevertheless, contain sufficient description to disclose or publish the invention so as to prevent its being validly patented by another subsequently. But I think it has been demonstrated that Varley's description was sufficient to enable a workman to make his machine. The model, No. 37, which everyone admits to be a model of a series-shunt wound machine, was made by a lad 19 years of age, apprenticed to an instrument maker, "from the information derived from Varley's patent with its drawings, and from nothing else." "It is entirely my own idea of Varley's patent." The same things was done by others. On the other hand, while there are witnesses brought to say that the description is misleading and inconsistent, no skilled workman has been brought to prove that having tried to make the machine from Varley's description he had been unable to do so.

It is further urged by the defenders that Varley had not when he invented his machine any knowledge of the value of series-shunt, and particularly of the quality of "constant potential," which by a series-shunt machine alone of the three I have mentioned can be approximately obtained ; that series-shunt was not in his mind, but some method of series-winding with a separate coil for separate excitation ; that, on the other hand, Brush knew the value of and was seeking to find a self-regulating machine. These matters have not, in my mind, any very direct bearing on the question at issue, but they require to be noticed. In the first place, Varley depones that in making his specification, he "understood the electrical significance of series-shunt winding," and I believe him. It is only due to Mr. Varley that I should say that, whatever may be the soundness or otherwise of his electrical theories, there is no doubt in my mind of his honesty. When he speaks to facts, I think he may be entirely relied on. In the second place, whatever value Varley placed on the compound winding of his machine, it was not in his view to make a machine which should proceed on the principle of separate excitation within the machine itself. He made a drawing (No. 40 of process) in November, 1876 (before the date of his provisional specification), which shows that he intended his machine to be a series-shunt, and not a series with separate excitation. With regard to that drawing, Prof. Silvanus Thompson says : "So far as that drawing goes, it indicates a series-shunt arrangement." In the third place, without expressing any opinion as to what may have been the state of knowledge of either Varley or Brush before 1876 or 1878 as to the value or obtainability of "constant potential," it is certain that neither of them in their respective specifications say anything to indicate their appreciation of the value of that quality or disclosed any view whatever as to the mode in which it was to be obtained. Even in 1878 constant potential was not felt to be a desideratum in electrical machines; and in regard to this matter, Varley and Brush, for all that appears, stand on an equal footing.

Lastly, on this branch of the case I have to notice that the defenders rely very much upon the fact that Varley in his specification did not claim the invention of compound winding. But Varley explains why he did not do so, and I have no doubt his explanation is true. Perhaps he was too timid ; perhaps he had given a construction and attributed a value to his brother's communication which it would not bear and did not merit. And yet it appears that another skilled electrician at first reading took the same view of that communication which Varley did. But the fact that Varley did not claim a certain invention is no proof that he did not publish it.

I come now to the question whether the defenders' machine was anticipated by user. A machine was constructed under Varley's specification in 1876 or 1877, which is produced. I think it is proved to be a series-shunt machine. It has the two coils of wire round the magnets, one of greater resistance than the other, and was capable undoubtedly of being worked as a series-shunt, having an appropriate commutator for that purpose. But some of the defenders' witnesses say it was a merely experimental machine, and could be connected in a variety of ways. It was certainly not worked as a series machine with separate excitation, for the commutator used was quite inappropriate to, and negatived, the idea of such use. How was it connected ? Varley says, "The machine No. 29 was connected exactly in the way that is represented by that diagram" (No. 40). Sir William Thomson says that diagram represents series-shunt. He is asked, "If you were told as a fact that this machine had been connected in accordance with the device shown in that sketch, would that convey to your mind a certainty that this machine had been worked as a series-shunt machine ?" And he answers, "Yes." There are other signs spoken to, which in the opinion of some of the witnesses indicate that the machine was worked as a series-shunt—but there are contrary opinions also. I rely upon the evidence of Varley that his machine, which was undoubtedly capable of being connected and worked as a series-shunt, was so connected and worked. He knew best how his machine was connected, and, as I have said, on any matter of fact, I have no doubt of Varley's accuracy and truthfulness. Then if it was so worked it was worked publicly. It was used publicly to illustrate certain operations in a diving-tank, and for the purpose of photographing an ice-machine. These were not experiments on the machine itself. They were the application of the machine to business purposes made in the presence of the public without secrecy or concealment. Very little use of a machine in such circumstances will constitute proper use. "If it is proved distinctly," said Lord Lyndhurst, "that a machine of the same kind was in existence, and was in public use—that is, if use or if trials had been made of it in the eye and in the presence of the public—it is not necessary that it should come down to the time when the patent was granted If it was discontinued, still that is sufficient evidence of the prior use so as to invalidate the letters patent." Such use of Varley's machine is I think distinctly proved.

I am, therefore, of opinion that the defender's machine was antici-

Digitized by Google

pated by Varley's, both by publication and user, and that the defender's patent is therefore invalid. I therefore give decree as concluded for, with expense.

CITY NOTES.

Brazilian Submarine Telegraph Company, Limited.—The traffic receipts of this Company, for the week ended June 21, amounted to £2,414.

Eastern Extension Telegraph Company, Limited.—The Directors of this Company have declared an interim dividend of 2s. 6d. per share for the quarter ended March 31 last, payable on the 15th proximo.

Western and Brazilian Telegraph Company, Limited.—This Company's receipts for the week ended June 21, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £1,567.

NEW COMPANIES REGISTERED.

Wolverhampton Electric Light and Power Company, Limited.—Registered by Waterlow Bros. and Layton, Limited, 24 and 25, Birchin-lane, E.C., with a capital of £50,000 in £10 shares. Object: to establish and carry on in Wolverhampton, or within 10 miles thereof, works for the purpose of the production, transmission, storage and use, by any means, and for any purpose of light, heat, electric, magnetic, or other force, and to supply to corporations, companies, firms, persons, or municipal bodies or authorities of any kind, light, heat, or force upon such terms as the Board may at any time think fit. The first subscribers are:
